Spherulites are commonest in acid glassy rocks but occur also in basic glasses such as tachylyte. Sometimes they compose the whole mass; more usually they are surrounded by a glassy or felsitic base. When obsidians are devitrified the spherulites are often traceable, though they may be more or less completely recrystallized or silicified. In the centre of a spherulite there may be a crystal (e.g., quartz or felspar) or sometimes a cavity. Occasionally spherulites have zones of different colours, and while most frequently spherical they may be polygonal, or irregular in outline. In some New Zealand rhyolites the spherulites send branching "cervicorn" processes (like stags' horns) outwards through the surrounding glass of the rock. Long, elliptical or band-like spherulites are called axiolites.

Spherulites may be ½in. or more in diameter. In composition they are a mixture of quartz and acid felspar.

Very large and cavernous spherulites have been called lithophysae; they are found in obsidians at Lipari, the Yellowstone Park, etc. The characteristic radiate fibrous structure is usually conspicuous, but the fibres are interrupted by cavities which are often so arranged as to give the spherulite a resemblance to a rosebud with folded petals separated by arching interspaces. Some of these lithophysae are rin. or more in diameter. In the crystallization of a glass there must be contraction, and it is supposed that thus the concentric cavities arise. The steam and other vapours in the magma would fill these empty spaces and exert a powerful mineralizing action on the warm rock. Analogous structures may be produced in artificial glasses, salt solutions and melts of organic substances. (J. S. F.)

**SPHINX**, the Greek name for a compound creature with lion's body and human head (Gr.  $\sigma\phi l\gamma\gamma\epsilon\nu$  to draw tight, squeeze). The Greek sphinx had wings and female bust, and the

male sphinx of Egypt (wingless) is distinguished as "androsphinx" by Herodotus The type perhaps originated in Egypt, where a defined type is usually recumbent. The most celebrated example is the Great Sphinx of Giza, 189ft. long, a rock carved into this shape, and from its situation likely to be the work of the IVth Dynasty.

According to inscriptions of the XVIIIth Dynasty in the shrine between the paws, it represented the sun god Harmachis It has recently been completely excavated and its head restored. Sphinxes of granite, etc., occur of the XIIth Dynasty and later. (See EGYPT. Art and Archaeology.) The heads of the sphinxes are royal portraits, and apparently they are intended to represent the power of the reigning Pharaoh. The king as a sphinx, in certain religious scenes, makes offerings to detities; and elsewhere he tears his enemies in pieces. Sphinxes in pairs guarded the approach to a temple, and the Great Sphinx at Giza so guards the entrance of the Nile valley.

The great temple avenues at Thebes are lined with recumbent rams, true sphinxes (a few late instances), and with the so-called criosphinxes or ram-sphinxes, having lion bodies and heads of the sacred animal of Ammon. A falcon-headed sphinx was dedicated to Harmachis in the temple of Abu Simbel, and is occasionally found in sculptures representing the king as Horus, or Mont, the war-god. It is distinguishable from the gryphon only by the absence of wings.

In Assyria the sphinx appears with a bearded male head on cylinders; the female sphinx, lying down and furnished with wings, is first found in the palace of Esar-haddon (7th cent. B.C.). Sphinxes have been found in Phoenicia, one at least being winged and another bearded. They are copies of the Egyptian, both in form and posture, wearing the pshent and the uraeus, but distinguished by having the Assyrian wings. The sphinx is common on Persian gems, and the representations are finely executed. On a Persian intaglio are two sphinxes face to face, each wearing a tiara and guarding a sacred plant which is seen between them; but the sphinx, whether of the Egyptian or the Assyrian type, is not found in Persian sculptures (Perrot and Chipiez, History of Art in Persia, Eng. trans., London, 1892). In Asia Minor the oldest examples are the "Hittite" sphinxes of Euyuk. They are Egyptian sphinxes treated in the Assyrian style. They are not recumbent, and the hair falling from the head is curled, not straight, as in the true Egyptian sphinx.

In the early art of Cyprus (the half-way house between Asia and Greece) sphinxes of Greek type are not uncommon. On the other hand, on a gem of Phoenician style found at Curium in Cyprus there appear two male (bearded) sphinxes, with the tree of life between them. With regard to Greece proper, in the third tomb on the acropolis of Mycenae (c. 1600 B.C.) were found six small golden sphinxes; they are beardless, but the sex is doubtful.

Moreover, the sphinx (generally sejant, in the Greek fashion) was well-known in Minoan art. It occurs in ivory (couchant) among the Mycenean antiquities from Enkomi in Cyprus, in the British Museum. In the ancient tomb discovered in 1877 at Spata near Athens (which represents a kindred but somewhat later art than the tombs at Mycenae) were found female winged sphinxes carved in ivory or bone. Sphinxes on glass plates have been found in graves at Camirus in Rhodes and on gold plates in Crimean graves. Sphinxes were represented on the throne of Apollo at Amyclae and on the metopes at Selinus; in the best period of Greek art a sphinx was sculptured on the helmet of the statue of Athena in the Parthenon at Athens; and sphinxes carrying off children were sculptured on the front feet of the throne of Zeus at Olympia. There have been found in Boeotia terra-cotta figures of wingless sphinxes. Roman sphinxes of a late period have sometimes a man's, sometimes a woman's head with an asp on the forehead.

In Greek mythology the most famous sphinx was that of Thebes in Boeotia, first mentioned by Hesiod (Theog, 326), who calls het he daughter of Orthus and Chimaena According to Apollodorus (iii. 5, 8), she was the daughter of Typhon and Echidna, and had the face of a woman, the feet and tall of a lion and the wings of a bird She dwelt at the south-east corner of Lake Copais on a bald rocky mountain called Phicium (mod. Fagas), which was derived from  $\Phi \iota \xi$ , the Aeolic form of  $\sigma \phi_{\nu} \gamma \xi$ . The Muses taught her a riddle and the Thebans had to guess it. Whenever they failed she carried one of them off and devoured him. The riddle was this: "What is that which is four-footed, three-footed and two-footed?" At last Oedipus guessed correctly that it was man; for the child crawls on hands and feet, the adult walks upright, and the old man supports his steps with a stick. Then the sphinx threw herself down from the mountain.

Among the remains of the Mayan culture in Yucatan are found examples of sphinxes, male and female, which are not unlike those of Egypt and Asia Minor.

See Milchhöfer, in Mith. d. deutsch. archäol. Instit. in Athen (1879), p. 46 seq.; J. Ilberg, Die Splinv in der griechischen Sage und Kunst (1895); Sir R. C. Jebb's ed. of Sophoeles, Oed. Tyrann., app., note 12. (J. M. M.; H. R. H.)

SPICE-BUSH (Lindera aestivalis), a North American shrub of the laurel family (Lauraceae), allied to the sassafras and Oregon myrtle (qq.v.), native to moist woods from Massachusetts to Ontario and Michigan south to North Carolina and Kansas. It grows from 4 to 20 ft. high, with smooth fragrant twigs and foliage, and bears bright yellow flowers, which unfold before the leaves, and scarlet fruit (drupe), maturing in late summer. The similar hairy spice-bush (L. melissaefolia) is found in swamps in the southeastern states. The bark of L. aestivalis was formerly of high repute in household medicine, being used as a febrifuse.

SPIDER MONKEY, a group of tropical American monkeys known to zoologists as Ateles. They take their English name from the slimness of the body, the elongated limbs, and the long tail, the under surface of the prehensile extremity of which is naked. The thumb is rudimentary or wanting. Their long coarse hair and the broader partition between the nostrils distinguishes them from the woolly spider monkeys (Brachyteles). The species are arboreal. (See PRIMATES.)

SPIDERS, or Araneae, form a natural order of the class Arachnida (q.v.). They are distributed all over the world, from Spitsbergen, Greenland and Alaska in the north, to Tierra del Fuego, Kerguelen and Macquarie in the south, from sea level to 7,300 metres above it on Mt. Everest. They are found on the ground and on vegetation, in forests and in meadows, in swamps and in deserts, in human homes and in subterranean caves. One may see spiders skipping over the surface of stagnant water, running on the beach between tides and in the case of at least one species, living in air-filled tents under water. All spiders are easily distinguished from insects by the subdivision of their body into two portions only: the cephalothorax and the abdomen. The former is the result of a fusion of the head with the thorax. The fusion is so complete that the outlines of the head may be recognized only from the shallow depressions which separate its dorsal surface from that of the thorax. The abdomen is attached to the cephalothorax by a very slender pedicel, a feature which spiders share with some other Arachnida. But by far the most important character of spiders, separating them not only from other Arachnida, but from all other animals, is the presence of spinnerets on the abdomen. The spinnerets are modified appendages of the fourth and fifth abdominal embryonic segments and are supplied with silk-producing glands situated in the abdomen. The ducts of these glands open at the end of specially modified hairs, the socalled spinning tubes situated on the spinnerets. The silk is produced as a fluid which is pressed out of the spinning tubes and solidifies immediately on contact with the air. Among the Arachnida, the Pseudoscorpiones are also able to produce silk, but their spinnerets are at the end of the movable finger of the chelicerae; i.e., of the first pair of appendages situated in front of the mouth and the silk glands are not in the abdomen, but in the cephalothorax. Some Acari are also endowed with the ability to spin silk. In their case the 215A SPIDERS

silk glands are really modified salivary glands, as is also the case in such insects as moths. So the spiders are the only possessors of their type of spinning apparatus.

Besides common spinning tubes with very fine ducts, spiders possess also a few larger spinning tubes, so-called spigots, present in small, but fixed numbers among the hundreds of regular tubes. In some species the total number of spinning tubes was estimated to be as high as a thousand, but in others it is less than a hundred. A spider's silk thread, as seen with the naked eye, is in reality a cable composed

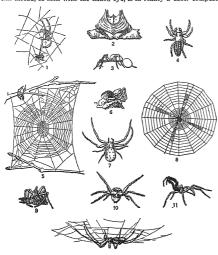

FIG. 1.-TYPES OF SPIDERS, VENOMOUS AND NONVENOMOUS

(1) Therdidis spider, wrapping a fiy in sticky throads; (2) Argloid spider, shown from behind (After Vinson); (3) Female Lycosid spider carrying egg cocono; (4) Common Attid spider (After Blackwall); (5) Epeirid spider and web (After Lulham); (6) Female Lycosa with egg sac attached to abdomen; (7) Thomasid spider (After Blackwall); (6) Argloid spider (After Hingston); (9) Grass spider (Agelena), pairing (After McCook); (10) Male Attid spider (After Bristowe); (11) Linyphid spider, on under side of her sheet web (After Blackwall); (12) Male Lycosa, in courting attitude (After Bristowe)

of many fine, individual threads. The diameter of such an individual thread is no more than three ten-thousandths of a millimetre, and in some cases, as in the inner lining of the cocoon of Agalena naevia, is less than one-tenth of a micromillimetre. Spider silk is finer, lighter and stronger than commercial silk produced by the silkworm; i.e., by the caterpillar of the silkmoth. Naturally, attempts have been made in the past to utilize spider silk, but without success. The reason for the failure lies in the cost of labour involved in the upkeep of a spider colony sufficient to produce large quantities of silk. In captivity each spider has to be kept separately and supplied with food and water, while under natural conditions the size of a garden adequate to accommodate numerous spiders, without danger of loss from overcrowding, is prohibitive from the point of view of reasonable profit. The most promising attempt at keeping spider gardens was made in Madagascar in the 19th century. The species used was the great orb-weaver, Nephila madagascarients. But even in Madagascar the cost of labour proved to be too high. At present spider silk is used only in the construction of optical instruments, because it is the finest thread available. For this purpose cocoons of northern species, such as the American Argiope auwantia, seem to be satisfactory. The length of the thread which Nephila uses in the construction of an egg cocoon varies from 1,500 to 4,000 cm etres.

All spiders have spinnerets, but one must not imagine that all make webs or snares. On the contrary, the majority of species use their silk for purposes other than the capture of insects: they spin egg cocoons, sperm webs, moulting sheets, gossamer threads, attachment discs with cables, lining of burrows, hinges for trap doors, etc., while relatively few species build snares of various types for the capture of prey. In using silk for different purposes, spiders do not use the same glands. Each spider has in its abdomen numerous glands belonging to several different types. Even males and females of the same species differ in this respect, because only females have glands producing silk for egg cocons. Only spiders which make snares to capture insects

produce silk with adhesive droplets. Since spinning of silk is so intimately connected with the activities of all spiders, it is clear that the spinning apparatus is one of the most important features of their anatomy and one of the chief factors which determined the course of their evolution.

Webs.—There are several types of webs built by spiders, more or less characteristic of whole families. One can distinguish sheet webs, funnel webs, tube webs, reticular webs, geometric orb webs, etc. In the early days of arachnology spiders were even classified in accordance with the type of web they build. Attempts have been made later in derive one type of web from another and thus to catablish trends in their evolution. Unfortunately all such attempts disregated other evidence of spider relationship and of changes involving the anatomical structure of various organs. In many cases comparatively close relatives belonging to the same family build webs of a very different type, while spiders belonging to wildly separated families may build webs of the same type. Thus so-called trap-door nests are characteristic of spiders belonging to the family Ctenizidae among the Mygalomorphae, yet some species of the Dipneumonomorph family Lycoside, notably the European Lycosa (Tarentialo) objics, make trap-door-nests of the same type. Theriduscoma nechodomae makes a little geometric spiral web, Epcirotypus gloriae, a triangular web and Wendigarda theridionina spins a single fine thread across brooks; yet all three belong to the same subfamily of orb-weaving spiders and occur in the same locality on the island of Puetto Rico. Litraphia marginata, a species common in Europe and America, builds a dome web, its close relative Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia communis makes an inverted dome or bowl web and another relative, Linyphia com

The most complex snares are undoubtedly those of the typical geometric orb-weavers of the family Argiopidae. A finished web consists usually of three or four outer foundation lines, several inner foundation lines, many radii, a central hub, an intermediate zone and a viscissiral. Besides this many species build a tent of silk or of a leaf rolled up and held together by threads of silk. In this tent the spider hides during the day, holding in its claws the guy line which is connected with the centre of the web and which transmits the vibrations caused by entangled insects. Before the adhesive spiral is made, the spider makes a corresponding spiral of common silk. When this is finished, the adhesive spiral is attached to the radii in the space between the turns of the common spiral. The latter is now clipped off, rolled up by the chelicare and dropped to the ground as having no further use. Species of Argiope weave additional X-shaped bands called stabilimentum, although they have nothing to do with stabilizing the web. Some weave in the middle of the orb a dusc of lacework. Cyclosa covica, a little orbewaver common both in Europe and America, suspends in the vertical diameter of her web a series of silk pellets to camouflage her egg

diameter of her web a series of slik pellets to camouflage her egg coon occupying a place in the same row.

The county occupying a place in the same row. The county of the county of the county occupying a place in the same row. The county occupied web is made by Hypochilus thorelli, a peculiar relict species found in the Great Smokies and adjoining mountain ranges in the United States and having close relatives only in Tasmania and China. Its web has the shape of a truncated cone suspended by the smaller, apical end from the underside of horizontal ledges, while the web, hangs freely down and is held in place by only a few threads. The long-legged spider sits inside the web, flattened against a flat foundation sheet, which is attached directly to the surface of the rock. Another very interesting same is made by Divopis longupes of Central America. The spider is long, with very long legs, the span of which measures as much as 150 mm. and when the spider hangs fully relaxed with legs and body stretched out in a single line, it looks more like a slightly curved twig than like a spider. It is suspended from a horizontal line by a single vertical thread, holding on to it with its spinnerets and its four posterior legs. With its four anterior legs, it holds the corners of a rectangular net made of special slik produced by so-called cribellar glands. When an insect falls on top of this trap, the spider immediately displays tremendous activity by swinging the trap in a spiral motion with great speed, until the victim is completely enswathed in silk. A new trap has to be built after each capture. Hyptiotes cavatus of America and Hyptiotes paradoxus of Europe, both belonging to the family Uloboridae, make triangular snares which they swing with the family Uloboridae, make triangular snares which they swing with the said of a guy line held in their legs. Their nearest relatives of the genus Uloborus construct orb webs of the same type as the Argiopidae, but use cribellar silk for the solar.

The construction of tents was already mentioned in connection with the building of orb webs. Many spiders of other families build tents which they use as retreats or hiding places in which they find shelter from rain, cold, light and enemies, or from which they can pounce upon unsuspecting victims. The European and Asiatic aquatic spider, Argyroneta aquatica, builds her tent under water in the shape of a bell and fills it with air. Special tents are often used for moulting, during which process all spiders, even the most formidable ones, are quite helpless. Some females make complete envelops of tough silk for themselves and their brood and stay inside until the spiderlings become capable of taking care of themselves. Some species winter in special tents made for that purpose under loose bark of trees.

Egg cocons present a great variety of structure. Some are circular or oval and perfectly flat. Others are globular and smooth. The egg-shaped, pointed cocons of Latrodectus geometricus are covered with numerous little knobs. Some cocons are white, others are coloured

yenow, brown, pink or green. The cocoon of Argiope argentata is a yenow, now, now, pank we geten. The coccon or Arginge argentata is a flat, elongated hexagon, often grass-green on one side and golden yellow on the other. The coccon of Hypochius therefil is white when made, but the female then camouflages it with pieces of moss which she collects from the surface of the rock or from the ground. Most foccoons are made with at least two walls, an inner and an outer one First, the spider spins a sheet, deposits the eggs in it, covers them with rits, the spice spins a sixty appoint the eggs in it could be another sheet and binds the two together, neatly clipping the edge. Then the outer sheath is made, often of much tougher silk. In Argope aurantic, the outer sheath or envelope is almost globular, made of brown, loosely woven silk. The inner sheath is cylindical, with a round bottom and a strongly constricted neck which protrudes through the top of the outer sheath. The cocoons of Agalena naevia, the common American funnel-web spider, are fastened under bark to which their flat base is attached. They are gray, unattractive and dirty looking. The female guards them until she dies.

guards them until she dies.

Attachment, discs or anchors are made by all spiders whenever they want to be safe from injury by falling from an elevation or when they jump from one place to another. An anchor is made instantaneously by pressing the spinnerets against the surface of the object on which the spider happens to be. The pattern of an anchor is characteristic of each species and consists of numerous loops of the control of the c fine threads brought together to a median line which is then conline threats brought together to a median me which is that con-tinued as a single cable. On reaching the object of its destination, the spider either breaks off the end of the cable or, if it mtends to return, fastens the end and climbs the cable to the point of its anchorage. Silk is used for enswathing insects captured in a sna.e. This makes

their escape impossible and serves to store them as food for use at a later time. In case the insect is a dangerous adversary, such as a wasp or hornet, silk may be squirted as far as an inch from the spin-

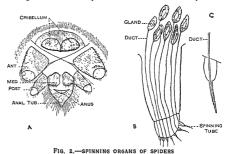

nerets, a distance sufficient to make the combat safe

nerets, a distance sufficient to make the combat safe. The maximum number of spinnerets which a spider may possess is four pairs. This number, however, is found only in the Liphistic nouphae. In some spiders the anterior median pair is transformed into a flat, perforated plate, the cribellum. In most spiders only six or four spinnerets are present. A few species are known with a single pair of spinnerets, the minimum possible, because the complete loss of spinnerets would require such a readjustment of habits, that the very existence of such creatures would become impossible. The size very existence of such creatures would become impossible. The size and shape of spinnetes, on the other hand, may vary considerably and apparently have very little to do with the type and complexity of the web. Spiders belonging to the Mygalomorph family Dipluridae have very long and slender spinnerets. They make large, irregular sheet webs or reticular webs which are usually provided with a funnel-like retreat, whereas spiders of the Dipneumonomorph family Hersiliidae, also with very long and slender spinnerets, make no webs of any kind.

Reproductive Organs.—Another character which spiders alone possess and by which they differ from all other animals is of a sexual nature: it consists in a complete separation of the male copulatory apparatus from the reproductive system pioper. The latter is situated in the abdomen in both sexes. The female has two ovaries, two oviducts and a single, very short uterus which opens in the median line

ducts and a single, very short uterus which opens in the median line between the organs of respiration belonging to the second embryonic segment. Another pair of openings is situated in front or at the sides of the genital opening. These openings lead into sperm receptacles. or the gentral opening. Iness uponings read into sperim receptactes. In more highly developed spiders the latter are connected with the uterus by special fertilization ducts. Various chitinous accessory structures, known as the epigynum, are present in many species. These are more or less intimately connected with the genital opening, are characteristic or the species of the connected with the genital opening, are characteristic or the species of the s more or less intimately connected with the genital opening, are characteristic of each species which possess them and in some way, not yet clearly understood, have to do with the act of copulation. The reproductive organs of the male are also in the abdomen. They consist of a pair of sperm glands or testes, a pair of deferent ducts and a short, common ejaculatory duct. The male genital opening is in the identical position described for the female genital opening. But the organs of copulation are in no way connected with the reproductive organs and are instead situated on the terminal joint of the pedipalpi. This is what makes them unique in the entire animal kingdom and organs and are instead situated on the terminal joint of the pedipalpi. This is what makes them unique in the entire animal kingdom and what necessitated the development of special instincts, of strictly inherited behaviour of male spiders, peculiar to sexually mature male spiders and only to them. Because the female has a pair of seminal receptacles and the male has a pair of pedipalpi, the males have a pair of copulatory organs. In its simplest form the apparatus consists of a bulb ending in a more or less curved spout or embolus. Inside the bulb a blind receptacle for sperm is situated, with a single duct which opens at the end of the embolus. The receptacles have to be filled with sperm before copulation can take place. This requires the construction of a special sperm web, the ejection of the sperm into the web and its transfer into the palpi through the opening of the embolus. How such an arrangement could have originated remains the web and its transfer into the palpi through the opening of the embolus. How such an arrangement could have originated remains a mystery. We have something similar in the case of the Ricinulei, another order of Arachinda, in which the metatarsus and tarsus of the third pair of legs in the male is modified as an organ of copulation. We find something similar, but without any structural modification, in the Solifugae, also an order of Arachinda, in which the male transfers the sperm into the genital opening of the female by means of his chelicerae. We do not know in which geological age the pedipalp of male spiders became modified as an organ of copulation. Oligocene spiders of the Baltic amber and Tertiary spiders of the Florissant shale possess fully developed copulatory organs of the same type and as complicated as recent spiders. The Mesozoic era left a single record of a tossil spider and that so imperfect that nothing can sugge record of a cossil spacer and that so imperiect that nothing can be learned from it. The tew fossil spiders from the Upper Carbon-iferous of Europe and Pennsylvanian of North America, as well as the still fewer tossils found in the Devonian red sandstone of Scotland, are not sufficient to determine whether at that distant age male spiders had as yet unmodified pedipalpi, or whether all available fossil specimens belong to the female sex or at most represent immature individuals. But it is clear that whatever the geological age may be when the pedipalpi became modified into organs of copulation, the change must have involved a corresponding change in sexual habits and this, in its turn, required a change in other habits. It is quite possible and even probable that previous to the development of organs of copulation on the pedpalpi, male spiders used a method of iertilization comparable to that of pseudoscopions. The males of these Iertilization comparable to trant of pseudoscorpions. In males of these small Arachinda attach a spermatophore to a stalk on the ground, grasp with the pincers of their pedipalpit the corresponding pincers of the female and drag her until her genital opening comes in contact with the spermatophore. Since spiders have no pincers on their pedipalpi, or for that matter on any other appendiages, males could never grasp a female in the manner of the pseudoscorpions. But they could perhaps have used their pedipalpit to hold a drop of sperm by could peniagis may ease their peningint to note a drop of sperin by simple adhesion and transferred it into the gential opening of the female in the best way possible, or may have dropped sperm onto a web and pushed the female until her genital opening came in contact with it. With the development of a special copulatory apparatus in the male, the development of sperm receptacles in the female must have gone apace until the bewildering diversity and complexity of structure and habits has been reached, by which the many thousands of species of spiders are now better distinguished than by other

Poison.—The third character which is found only in spiders among Arachnida is the presence of poison glands either in the basal joint of the chelicerae or in the cephalothoiax and opening by means of a of the chemical of in the Cephanonical and opening by means of a duct near the tip of the fang. With few exceptions the structure of the glands is the same in all spiders. It is an elongated, cylindrical sac, the walls of which have a single layer of glandular epithelial cells and an outer muscular covering composed of spirally wound, striated fibres A structureless membrane separates the two layers and another thin membrane formed by highly flattened cells protects the outside of the gland. The flow of poison is under control of the spider. In

(A) Spinnerets of Eresus latifasciatus, ventral view; (B) One of the spinnerets of Trechalea magnifica, showing slik plands and duots; (C) Greatly enlarged spinning tube of Trechalea magnifica

fact, spiders which ensnare their prey do not use their poison, while those who hunt for their prey or hide on flowers and capture insects by grasping them with their fangs when the insects come within their by grashing mean with their actings when the insects come within their reach, kill their victims with poison. All spiders, however, use their poison in self defense, when escape is impossible. Spiders of two families, Uloboridae and Heptathelidae have no poison glands.

The poison of spiders attracted early attention and was studied many times. Unfortunately, the results of most of such studies are

many times. Comortunately, the results of most of study stimes are vitiated by the application of wrong and faulty methods. Observations on the effects of bites on man and animals are of very little value even when the species of spider is known and at best may serve only as confirmatory evidence. But experiments conducted in the laboratory have also led to wrong conclusions until ways were found laboratory have also led to wrong conclusions until ways were round to get the poison in a pure state, without any admixture of other substances such as invariably happens when an entire cephalothorax is used for extraction of poison in a fluid. As now practiced, poison is obtained either by dissecting the cephalothorax and removing the glands, or still better by applying an electric current to the immobilized, live spider and collecting the pure poison as it appears in droplets at the ends of the fangs. Poison obtained in this manner may be dried, weighed and used in measured quantities and known concen-

tration. Few spiders are poisonous to man. Among these the black widow alone is dangerous in the United States, as are other closely related species in Europe, Africa, Asia and Australia. All these species belong to the genus Latrodectus of the family Theridudae and their poison is neurotoxic. The only other spiders known to have a neuro-

SPIDERS

toxic poison belong to the genus Ctenus of the family Ctenidae A Brazilian species, Lycosa raptoria, causes a creeping ulceration of the skin. Some observations point to the possibility that other species belonging to various families may be poisonous to man. But the majority—even large tarantulae—are no more dangerous to man than wasps or hornets and a great many spiders do not attempt to bite

even when taken in one's hand.

Respiratory System .- A fourth feature peculiar to spiders among other Arachnida is the presence of two types of respiratory organs in the same individual, book lungs and tracheal tubes. This peculiarity is restricted to a single suborder among the spiders, th Dipneumonomorphae, but the vast majority of spiders belong to it. It seems certain that originally spiders had two pairs of book lungs and no tracheal tubes; the second pair was later replaced by tracheal tubes and finally the first pair was also replaced by tracheal tubes. Thus we have in spiders a condition unique among the Arachmda Of late, Tasmanian spiders have been discovered in which only one pair of tracheal tubes remains.

Digestive System .- Several features, while not unique among Arachnida, nevertheless are of great importance in the life of spiders The first of these has to do with the structure of their digestive sys-The first of these has to do with the structure of their digestive system. The foregut, consisting of a pharynx, oesophagus and gizzard, is concerned only with the mechanics of ingestion. The pharynx is so structured that it acts both as a pump and a strainer, preventing coarse particles from passing into the oesophagus. The latter is merely a tube connecting the pharynx with the gizzard, but the gizzard is a second, powerful pump. The mid-gut is provided with several a story connecting the party of with the gazzard, but the gazzard is a second, powerful pump. The mid-gut is provided with several branched diverticles, the finest branches ending each in a little spherical ampulla and the whole lot of them held together by interstitial tissue. The mid-gut serves two purposes: it produces digestive enzymes and absorbs the fluid substances into which food is converted after the action of enzymes on its constituents. A pair of maxillary glands situated in the maxillary lobes of the pedipalpi also produce digestive enzymes. The mid-gut forms a large stereoral pouch in which excrements are stored before they are excreted through the hind-gut and anus. Now this arrangement of the digestive system found also in other Arachnida, makes ingestion of only fluid food possible and necessitates predigestion of food outside the body. It is a mistake to think that spiders suck blood. That is the one thing they never do. Instead, they inflict a wound with their fangs, inject digestive enzymes into the wound and as the tissues of their prey become liquefied, pump the insect dry, leaving nothing but an empty, chitinous shell behind. For some reason which is not quite clear, spiders have never learned to make use of vegetal food or even to when the latter do not move. Spiders may be fed in captivity by little pieces of raw meat, but the latter must be attached to a thin thread and dragged or dangled in front of the spider to induce the latter to

Sense Organs.—The second feature which naturally has a great influence on the entire behaviour of spiders, is the structure and funcinfluence on the entire behaviour of spiders, is the structure and function of their sense organs. Spiders belonging to different families differ greatly in this respect. Some have well developed eyes with keen vision. Such spiders have less perfectly developed tactile organs other spiders have eyes with much poorer vision and depend more on the perfection of their sense of touch. The latter is the best developed sense even in spiders with good eyes, while in species with poor eyes it is almost unbelievably fine and diversified. The body and less that padigately and check the production of the spine of the spiders and summer the spine of the spiders and spiders and spiders and spiders and spiders and spiders are spiders. and legs, the pedipalpi and chelicerae and even the spinnerets of spiders are covered with numerous hairs of various kinds, some stiff splicers are covered with indicated and so various among, some since and stout, others slender and pliable, some smooth, others provided with serrations. Many spiders have plumelike soft hair. Some hairs lie flat on the surface of the skin, others stand at an angle of 30° or more, some are erect. Not all are sensory hairs, but each sensory hair has its own nerve fibre which conveys impulses to the central nervous system. Especially fine, erect hairs arising from the centre of little drumlike membranes, are sensitive to slow currents of air. Such hairs are called trichobothria and their distribution has systematic nars are called trichobothria and their distribution has systematic value. Once the trichobothria were suspected of being capable of transmitting sound-vibrations, but this proved to be incorrect. Many spiders possess sound-producing organs, but organs of hearing have not yet been discovered, nor is it known how acute hearing is in spiders. It is probable that the range of sounds which they can perceive is quite different from the range of the human ear and presumed by much bisher.

sumably much higher.

Except for a few blind species, all spiders possess eyes which are on the carapace. The maximum and most common number is four on the carapace. The maximum and most common number is rour pairs; but spiders with three, two, or a single pair of eyes are known. Some families have only six eyes, as for example the Dysderidae; but usually the reduction in the number of eyes occurs in different genera of the same family. The so-called anterior median eyes have always of the same ranky. The same ranky are a direct retina; i.e., one in which the rods face the dioptric apparatus, consisting of a glass body and a corneal lens. The other eyes have always an inverted retina and are often supplied with a tapetum of

pigment cells, reflecting light and giving the eyes a pearly appearance. The disposition of the eyes is characteristic of whole families and is responsible for the diverging directions of the axes of the eyes. Convergent eyes do not occur in spiders. The respective fields of vision are determined by the shape and curvature of the lens, the acuity of vision by their diameter, the size of the image and the distance at which the image of two points falls on a single rod. Each pair of which the image of a size different from that formed by the other eyes forms images of a size different from that formed by the other eyes and the fields of vision are mostly quite different. Thus a fairly large potition of the horizon is covered, but only small portions are ever covered by overlapping fields of four eyes, still smaller ones by six eyes and scarcely ever by all eight eyes. The best eyes have lenses with spherical surfaces, but the acuity of vision with even the best eyes is far below that of the human eyes.

with spherical structes, but the actiny of vision with even the best eyes is far below that of the human eyes.

The olfactory sense is very poorly developed and apparently restricted to what one may call sexual odours. The males of some species are able to follow the invisible spoors left by a female on a smooth surface, such as a sheet of paper. But other scents are not perceived unless the substance is of a highly irritating nature.

Behaviour.—Spiders have a highly developed nervous system, possess memory and their reflexes may be conditioned by methods used in such experiments. But since none of the spiders developed a social state comparable to that of insects and only few species at best may be said to be gregarious, the behaviour of spiders is entirely of the type usually spoken of as instinctive. Some of these patterns of inherited behaviour appear early and persist throughout life. Others appear at the time of sexual maturity and disappear rapidly. Generally speaking, the life cycle of a spider may be pictured as follows. A spiderling, on emergence from the egg, is incapable of taking care of itself, because its digestive system is not yet fully developed. The mid-gut is filled with embryonic yolk and ingestion of food is impossible. Consequently spiderlings either stay in a web built by their possine. Consequently spliceting statics as a ma we built by their mother mother for that purpose before she died, are guarded by their mother inside a brood-cocoon, or are carried by the mother on her back, as the case may be. Their life is restricted to slow digestion of the embryonic yolk. The completion of its digestion coincides with the completion of the digestive system itself and is accompanied by the shedding of the skin and some changes in the proportions of the body. With the mid-gut emptied, hunger sets in and the spiderlings would attack and destroy each other but for the simultaneous emergence of an inherited desire to escape. Dispersal of spiderlings may be accomplished by different methods. In some species, spiderlings simply run away in all directions. But in the majority of species aerial dispersal takes place. This so-called ballooning coincides in temperate persai taxes place. This so-tailed ballooning coincides in temperate zones with the sunny days of autumn or of spring, if the eggs remain quiescent through the winter. Each spiderling climbs to the end of a blade of grass, a twig, a pole or any protruding object, raises its abdomen and spins a thin thread of silk. As this gossamer thread is caught in the breeze, the spiderling lets go of the support on which it sat, climbs to the middle of the thread and is carried by air currents to a considerable height upward and to great distances horizontally. Gossamer threads have been encountered by aeroplanes five miles above sea level and one observer stated in a letter to the author that he saw spider threads in the stratosphere. Spiderlings have been also caught in the rigging of ships several hundred miles from shore. When other currents of air finally bring them down to the ground, when dude currents of an many bring their down to the ground, the spiderlings enter upon the new phase of their life, which will last until maturity. Each spiderling follows the pattern of behaviour characteristic of the species. Some build a web, orb web, sheet web, reticular web, etc., as the case may be, others make burrows or run about on the ground among leaves, remaining vagabonds without a home. From time to time they moult, shedding the entire skin, including the corneal lens of the eyes and the lining of the fore-gut and the organs of respiration. During this period the spiders are quite helpless and cannot eat nor bite. The number of moults varies in neipiess and cannot eat nor bite. The number of moults varies in different species and even in the same species, but the usual number is seven or eight and up to 13. Males of all species and most females never moult after maturity, only some Lycosidea and Theraphosidae do so. The usual behaviour of females is not appreciably changed when they become mature, except that sexual excitation becomes manifest and they respond to the advances of a male in a manner different from that which governs their attitude toward their prey or unwelcome intruders. Otherwise they still lead the same life, build the same type of snares, etc.

In the case of males, the entire behaviour pattern changes as soon

as they mature. The filling of their palpi with sperm is now their chief concern. The males of some species use the old web for the purchief concern. The maies of some species use the old web for the purpose, merely adding a few threads of silk to which they attach the drop of sperm as it comes out of their genital opening. Other species weave special sperm webs, even if they have never built a web of any kind before. The pumping of the sperm takes from 45 minutes to a hours time. When the palpi are charged with sperm the male goes in search of a female. This is a rather hazardous undertaking, considerate the fact that no female has ever seen a male in her life and sidering the fact that no female has ever seen a male in her life and that each female is familiar only with animals suitable for food or those that must be handled as enemies. Courtship is the means by which a male overcomes the hostile attitude of a female. In jumping spiders endowed with a good sense of sight, courtship consists of a love dance in the presence of a watching female, but at some distance

from her. In spiders with a less keen sense of sight, actions involving autobiography, Finder und Erfinder (2 vols., 1890). touch or smell or a combination of these two senses take precedence Some orb weavers show a discrepancy in the time of maturation, the males maturing considerably earlier than the females. In such cases one or more males get into the web of a female and live in it until she becomes mature. In some species the male builds a tent in which he stays with the immature female, sharing food with her until she moults for the last time. Some males offer a captured insect to the female to appease her hunger. Copulation lasts but a few minutes. The palpi are used one at a time and courtship is sometimes repeated in the interim. When both receptacles of the female are filled, the relationship between her and the male reverts to that between any two relationship between are and the mane reverts to that between any two spiders of the same or of opposite sex. The male being the smaller of the two and the more agile, seeks safety in escape. The female, with the sexual desire appeased and the feeling of hunger returning, treats the male as an intruder if he persists in remaining in her we or stays too close to her on the ground. But the often repeated stories that female spiders always devour their mate after copulation are based on misinterpretation of observed instances when a male was prevented from escaping and later fell victim to the hungry female. The majority of males die naturally soon after copulation, because the supply of their energy is completely spent. In captivity a male may linger for several weeks if kept alone, but he usually refuses food and dies with the abdomen showing considerable shrinkage of all

Females live longer. In some species they die soon after egg laying, remaiss live longer. In some species they due soon after egg laying, but in other species they may live several years and copulate annually. To the former group belong the majority of spiders in temperate zones, to the latter the larger Lycosidae and the Theraphosidae. Some large tarantulae are known to have lived in capitivity as long

as 15 years.

Spiders have many enemies among vertebrates and invertebrates. Many lizards, some toads and various birds feeding on insects also eat spiders. The large Bufo maritima was observed greedily feeding on hairy translulae. Solitary wasps are perhaps the greatest enemies of spiders. Many of them depend entirely on spiders as food for their larvae. Collectors know that the easiest way of getting certain for finer larvae. Concerns know main me easiest way or getting certain species of splicers is by examining the nests of mud daubers. Species of the genus Pepsia among solitary digger wasps paralize Mygalomorph spiders, bury them and lay a single egg on the abdomen of each victim. Some Hymenoptera and Diptera spend their larval life as external parasites of spiders. Nematodes of the family Mermithidae external parasites of spiders. Nematodes of the family Mermithidae are not uncommon parasites in the body cavity of spiders. Protozoan and helminth intestinal parasites have not as yet been found, perhaps because infection is impossible on account of predigestion and filtering

More than 50,000 species of spiders are known, distributed among more than 3500 genera and many new species are discovered every year. The spider fauna of Europe is known fairly completely, that of the United States much less so.

Palaeontology.-Fossil spiders have already been found in the

of the United States much less so.

Palaeontology.—Fossil spiders have already been found in the red sandstone of the Devonian. Many species have been described from the Carboniferous of Europe and America. A single species has been reported from the Mesozoic, but the Tertiary of Europe and America and particularly the Oligocene Amber of the Baltic are rich in fossil species the great majority of which are now extinct.

Bibliography —The following short list of books may be of help to the uninitiated. More or less complete bibliography published yearly will be found in the Zoological Record. L. Berland, "Les Arachnides," Encyclopédie Entomologique XVI (Paris, 1932); W. S. Bristowe, The Comisty of Spiders, 2 vols. (London, 1939-41); J. H. Comstock, The Spider Book, Revised by W. J. Gertsch (1940); Sukh Dyal, "Spiders of Lahore," Bull. Depth. Zool. Panjab Univ. (1935); U. Gerhardt und A. Kästner, "Araneaa," Kükenthal's Handbuch der Spinningwork, 3 vols., Philadelphia (1289-93); K. C. McKoown, Spider Wonders of Australia (Sydney, 1936); E. Nielsen, The Biology of Spiders, 2 vols. (Copenhagen, 1932); A. Petrunkevitch, Systema Aranearum, Trans. Conn. Acad., Vol. 29 (1928); C. Fr. Roewer, "Araneae," Die Tiervelle Mitteleuropas (Leipzig, 1928); Th. Savory, The Biology of Spiders (1934); E. Simon, Les Arachnides de France, 7 vols. (Paris, 1892-1903).

SPIELHAGEN, FRIEDRICH VON (1829-1917), German novelist, was born at Magdeburg on Feb. 24, 1829. He was

man novelist, was born at Magdeburg on Feb. 24, 1829. He was brought up at Stralsund, studying also at Berlin, Bonn and Greifswald. He became a master in a gymnasium at Leipzig, but upon his father's death in 1854 devoted himself entirely to writing. After publishing Klara Vere (1857) and Auf der Düne (1858), he obtained a striking success with Problematische Naturen (1860-1861). His powerful Sturmflut appeared in 1876. He died

Feb. 25, 1911.

Spielhagen's Sömtliche Werke were published in 1871 in sixteen volumes, in 1878 in fourteen volumes; his Sömtliche Romane in 1898 (22 vols.), and these were followed by a new series in 1902. See his

SPIKENARD or NARD, a celebrated perfume which seems to have formed one of the most durable aromatic ingredients in the costly unguents used by the Romans and Eastern nations. The ointment prepared from it is mentioned in the New Testament (Mark xiv. 3-5; John xii. 3-5) as being "very costly," a pound of it being valued at more than 300 denarii (over £10). This appears to represent the prices then current for the best quality of nard, since Pliny (H.N. xii. 26) mentions that nard spikes reached as much as 100 denarii per lb. The source of the true or Indian nard is now identified as Nardostachys jatamansi, a plant of the family Valerianaceae, the fibrous root-stocks or "spikes" of which are still collected in Bhotan and Nepal.

The great spikenard of the United States is Aralia racemosa, and another species of the same genus, A. nudicaulis, or wild sarsaparilla, is known as "wild spikenard." In the West Indies Hyptis suaveolens is called "spikenard," and in Great Britain the name "ploughman's spikenard" is given to Inula squarrosa (I.

SPILITE, in petrology, a rock of basaltic character, but possessing in place of the normal labradorite, a felspar of the composition of albite. The ferromagnesian mineral is an augite of pale brown colour; spilites are, however, usually very completely decomposed, augite being represented by chlorite and calcite. They are commonly vesicular or variolitic and show wonderfuly preserved pillow structure, a feature in most cases indicative of a submarine origin of the lavas. The individual pillows are filled with concentric zones of vesicles filled with chlorite and calcite. The formation of pillow structure in volcanic rocks has been directly observed by Dr. Tempest Anderson in the case of the lava poured into the sea from the volcano Matavanu, in Samoa. On the surface of the lava, buds form and expand, giving rise to "pillows" with a glassy crust. The interspaces between the pillows are frequently filled with sediment representing the soft ooze of the sea floor. Not all pillow lavas are spilitic in character.

Some spilites showing pillow structure are not strictly lavas but shallow intrusions into unconsolidated submarine ooze. Excellent examples of such intrusive spilites are provided by the Devonian spilites of Nundle, New South Wales. Though the term spilite was first used by Brongniart for altered basic lavas free from phenocrysts and possessing well marked vesicular textures, a new significance was given to the term by Dewey and Flett, who urged that a special group of rocks-the spilitic suite-should be recognized. According to these authors, a large suite of igneous rocks is genetically associated with the spilites. Their composition varies widely, but they all have some characters in common. They possess a high percentage of soda and are usually extensively altered. These rocks are albite-dolerites, minverites, picrites, keratophyres, soda-felsites and soda-granites. The spilitic suite was originally given a status comparable with that of the alkaline and calc-alkaline suites. The spilitic series is regarded as peculiar to districts that have undergone a long continued and gentle subsidence with few or slight upward movements and no important faulting. The lavas are poured out on the margins of geosynclines while their common sedimentary associates are black shales, limestones and radiolarian cherts. As geosynclines are the centres of subsequent fold movements many ancient spilites have become extensively folded and metamorphosed with production of new minerals, including albite of metamorphic origin. Eruptions having the spilitic facies have occurred repeatedly over a wide area and on a large scale. The analyses of average basalt and spilite are as follows:

	SiO <sub>2</sub>	A12O2	Fe <sub>2</sub> O <sub>3</sub>	FeO	MgO	CaO	Na <sub>2</sub> O	K20	H2O(+)	TiO	co <sub>z</sub>

SPINA, an ancient city of Gallia Cispadana, Italy, between Ravenna and the mouths of the Po. In Etruscan times it was the principal port of Felsina. (See Bononia.) Near Comacchio, in the draining of the lagoon of Valle Tiebba, a very extensive necropolis has been found and some 450 tombs have been excavated, ranging from the 6th to the 3rd century B.C. They contained fine

Greek, Italic and Etruscan vases.

SPINACH (Spinacia oleracea) (family Chenopodiaceae), a hardy annual of Asiatic origin, long cultivated for its succulent leaves for use as a pot-herb. When sown in the fall at the proper time it will survive winter temperatures occasionally near oo F; when so grown it behaves as a biennial. The prolific rosette of leaves that first develops is harvested in entirety before the appearance of the seed stalks which develop rapidly to 1 to 3 ft. during warm, long days. The plant is sensitive to day length, and temperature; cool weather or short days are conducive to luxurous rosette development and retardation of seed stalk formation; hot weather or long days induce seed stalk formation. Male and female flowers are generally separate plants, the male flowers in terminal spikes and the female flowers (and fruits) in the axils of the branches and leaves. The so-called "seed" is a fruit consisting of a compressed seed together with the surrounding calyx lobes that may be either smooth or prickly.

Spinach can be grown as a summer cuop only in distinctly cool climates. It requires very rich, well-watered, well limed soil. In the United States it is grown very extensively as a fall, winter, or sping crop with plantings to coincide with suitable temperatures. In gardens it is sown thinly in rows 8 to 18 in. apart and the plants thinned to stand 3 to 4 in. apart. In many large fields it is sown in rows 8 in. apart, or even broadcast, and given no thinning or cultivation. Arti-

ficial protection is rately given duting winter.

Spinach culture in the United States received an enormous impetus about 1920 when attention was called to its relatively high content about 1930 when attention was taned to its featively high content of calcium and iron, and further impetus when its relatively high content of vitamins A and C were emphasized. The later discovery of large quantities of oxalates in the plant has cast some doubt upon its true dietary value, but it continues to be a most popular pot-herb. Its culture increased from about 6,000 ac. in 1918 to over 107,000 ac.

in 1937, after which it gradually declined to about 75,000 ac. in 1941.

New Zealand Spinach (Tetragonia expansa) (family Mesembry-accae), a tender annual, native to New Zealand, produces "greens" similar to spinach, when cooked. It is a much-branched, spreading plant I to 2 ft. high, with fleshy, triangular leaves and inconspicuous, yellow-green, axillary flowers. The "seed" is a nut-like fruit containing one to two seeds that often germinate very slowly. The plant is frosttender and heat tolerant, furnishing "greens" at a season when other pot-herbs do not thrive in warm regions. It is sown in rows 2 to 3 ft. apart, with the plants about 1 it, apart in the rows. The leafy tips of the branches are harvested repeatedly as new growth develops.

Mountain Spinach or Orach (Atriplex hortensis) (family

Chenopodiaceae), of Asiatic origin, is a coarse, hardy annual growing to a height of 6 ft. The leaves are large, triangular-ovate or arrow-shaped, with toothed or wavy margins and colour varying from pale yellow-green to dark red. The leaves are used as a pot-herb, but the plant is of little interest to European or American gardeners except in regions not suited to the culture of the commoner leafy vegetables, as the Great Plains of the United States.

SPINAL COLUMN, SURGERY OF. Most operations on the vertebral column are designed to relieve some condition of the enclosed spinal cord. The essentially degenerative diseases (tabes dorsalis, disseminated sclerosis, etc.) offer little scope for surgery, which finds its richest field in cases of cord compression. Spina bifida, a congenital defect in development, calls for operation in se-lected cases only, for most sufferers from this condition die during the first weeks or months of life. There is one fundamental fact which we must grasp if we wish to understand the possibilities of spinal surgery: that regeneration is impossible, so that once the cord, and the long conduction tracts of which it is composed, suffers actual anatomical

conduction tracts of which it is composed, states actual ammoniacal damage, that damage is permanent and cannot be undone.

Spinal Injuries.—These are generally due to indirect violence, the fracture occurring at a point distant from that at which the force was applied. Thus most injuries of the cervical spine (neck) are due to injuries applied to the head, while forcible flexion of the trunk by a weight failing on the shoulders (the common mechanism in pit accidents from a fall of "roof" or "dirt") causes a fracture at the first lumbar vertebra. The 24 bones which make up the cervical, thoracic and lumbar spine are not equally prone to injury; the three predominant sites where fractures or dislocations occur are at the points where the qualities and range of movement change—at the second cervical, where the compound movements of the head change over into the where the compound movements of the head change over into the ordinary movements of the neck, at the disc between the fifth and sixth cervical where the cervical mobility changes into the relative fixity of the chest, and at the first lumbar where the latter joins the rod-like lumbar portion. The bodies of the vertebrae can be compressed or broken without failury to the spinal cord (so-called "Kümmells' disease") provided there is no sliding of the broken parts on one another. A fact which colours our whole attitude towards spinal injury to-day is that when the cord is damaged the lesion is inflicted at the moment of injury. The old teaching was that the cord was being compressed by bone fragments and hence early operation was

advised. To-day we treat these cases with conservatism, reduce fracadvised. To-day we treat these cases with conservatism, reduce hac-tures by manupulation, and operate only when deterioration is setting in or pain is severe. But operation is never done as an immediate urgency. X-Rays are of the greatest help. In summary, the cord-lesion associated with most impures is central haemorrhage or actual laceration, and operation will not often be of service in the worst cases.

Spinal Tumours.—Once the diagnosis is reasonably certain it is best to operate early, for these growths are commonly (Elsberg gives \$2%) outside the cord and can be dislodged by laminectomy. An incision is made over the spinous processes, the laminae are exposed by clearing the muscles with a rongeur and some three of them are removed. The dura mater is incised, if the tumour has not already been found outside. The results in many cases are dramatic and the palsied may indeed be made to walk upright. When the tumour hes in the therapy is the only hope for such conditions, but only a few successes have so far been recorded. Little noticeable weakness follows a laminectomy per se.

Spinal Caries .- Tuberculosis of the vertebral column is commonest in the very young, and gives good results by fixation on fiames or in plaster jackets. Long periods of recumbency (1-3 years) are generally required. In order to render sufferers ambulant at an earlier time, bone-grafting operations have been devised. Albee advised this so-called "internal spinting" and recommended that a long thick graft should be taken from the tibia and inserted into a bed prepared grant should be taken from the thola and inserted into a beg prepared for it over the bared spinous processes and laminae at the region affected, including two healthy vertebrae above and below. Hibbs later introduced the operation of "spinal fusion"; in this no new bone is implanted but the spinous processes and laminae are split and turned up and down to produce a mass of bone which will lock the turned up and down to produce a mass of bone which will lock the bones together. The operations are most useful in persons of less tender years than are the majority of sufferers from Pott's disease. In Great Britain and Europe generally, excellent results are obtained by less drastic means, but in those who cannot afford a long con-valescence these operations should be considered. Sometimes a tuberculous abscess forms within the neural canal,

extends backwards from the diseased vertebrae, and presses on the cord. Happily most of these patients recover the function of their limbs when perfectly immobilized; laminectomy does not give the good results which one might theoretically expect from it.

Pain .- Much can be done for sufferers from agonizing pain by judicious spinal surgery. The chief indications for operation are neuralgia of the body or limbs, often the sequelae of amputations or of herpes zoster, the agonizing pains of spinal syphilis, and hopeless malignant growths. The usual operation heretofore has been section of posterior nerve roots just before they enter the spinal cord. The exposure is the same as for spinal tumours. The results of root sections have been inconsistent, and the operation is being replaced by section of the pain-carrying fibres in the cord itself (Spiller). This tract is the anterior spino-thalamic and lies just sufficiently far away from the motor pathway to the limbs (pyramidal tract) for its division to be effected without inflicting paralysis on the sufferer. As the sion to be enected without minicting paralysis on the suiterer. As the pain fibres cross in the cord, the tract of the opposite side to that on which the pain is felt is the one to be cut, and of course at a point cephalad to the site of the pain. A cut 2,5 to 3,0 mm. deep is made into the anterolateral aspect of the cord. A very fine and sharp knife is required and the operation must be most delicately and precisely performed. Brilliant results have generally followed, but it is too early to say what the late effects are.

Spinal Puncture.—No account of modern spinal surgery can omit some reference to the extended usefulness which is being made of lumbar puncture (puncture into the subarachnoid space and withdrawal of a specimen of cerebrospinal fluid). Our knowledge of the changing chemistry of that fluid in disease conditions is still growing. When a tumour or the like grows in relation to the spinal cord it causes a block in the subarachnoid space, either by its own bulk or causes a block in the subarachnoid space, either by its own bulk or by compressing the membranes against one another should it be extradural. The cerebrospinal fluid distal (caudal) to the obstruction is dammed back, for it is chiefly absorbed within the skull and thither it can not now return. A rise in albuminous content and a yellow tinge, xanthochromatosis (Froin's syndrome), are the results. This is of great diagnostic importance. Queckenstedt's test also makes use of of great magnostic importance. Queekensteers test also makes use of the block, for when a normal person's jugular veins are compressed the consequent rise of intracranial venous pressure is transmitted to the cerebrospinal fluid as a whole and can be measured by a manometer attached to a lumbar-puncture needle. If a tumour blocks the spinal canal the manometer records no change or modified changes only. This is most valuable in differentiating between the degenerative and compression groups of paralysis of the lower limbs Lastly, Lipidol, a heavy, opaque substance which when introduced into the cerebrospinal fluid above the tumour sinks down through it to rest on the tumour, is proving most useful. It is a 40% solution of inert iodine in poppy-seed oil and is quite opaque to X-Rays so that the precise position and often the shape of the upper end of the tumour becomes definitely recognizable.

SPINAL CORD, in anatomy, that part of the central nervous system in man which lies in the spinal canal formed by the vertebrae, and reaches from the foramen magnum to the lower

margin of the first lumbar vertebra. It is about 18in. long, and only occupies the upper twothirds of the spinal canal The cord is protected by the same three membranes which surround the brain. Outside is the dura mater, which differs from that of the brain in not forming a periosteum to the bones, in sending no processes inward, and in having no blood sinuses enclosed within its walls; it is the continuation of only the inner layer of the dura mater of the skull. Inside the dura mater is the arachnoid, which is delicate and transparent, while between the two lies the subdural space, which reaches down to the second or third sacral vertebra. The pia mater is the s innermost covering, and is closely Fig. 1-SPINAL CORD, SHOWING applied to the surface of the cord TRACINGS OF ANTAGONISTIC REinto the substance of which it FLEXES

sends processes. Between it and the arachnoid is the sub-arachnoid space, which contains the cerebro-spinal fluid. Across this space, on each side of the cord, run a series of processes of the pia mater arranged like the teeth of a saw; by their apices they are attached to the dura mater, while their bases are continuous with the pia mater surrounding the cord. These ligaments, each consisting of twenty-one teeth, are the ligamenta denticulata, and by them the spinal cord is moored in the middle of the cerebro-spinal fluid.

The spinal cord itself is a cylinder slightly flattened from before backward. In the cervical region it is enlarged where the nerves forming the brachial plexus come off, while opposite the lower thoracic vertebrae the lumbar enlargement marks the region whence the lumbo-sacral nerves are derived. (See fig. 2.) Opposite the second lumbar vertebra the cylindrical cord becomes pointed and forms the conus medullaris, from the apex of which a glistening membranous thread runs down among the nerves which form the cauda equina, and, after blending with the termination of the dural sheath, is attached to the back of the coccyx.

Details of Structure.-In a transverse section of the cord (see fig. 3) two median fissures are seen; the antero-median is wide, and reaches about a third of the way along the anteroposterior diameter of the cord; it is lined by the pia mater and, in front, lies the single anterior spinal artery.

The postero-median fissure is much deeper and narrower, and has no reflection of the pia mater into it. Where the posterior nerve roots emerge is a depression which is called the posterolateral fissure, while between this and the postero-median a slight groove is seen in the cervical region, the paramedian fissure (see also fig. 2). The anterior nerve roots do not emerge from a definite fissure.

The spinal cord, like the brain, consists of grey and white matter, but, as there is here no representative of the cortical grey matter of the brain, the white matter entirely surrounds the grey. In section the grey matter has the form of an H, the cross bar forming the grey commissure. In the middle of this the central canal can just be made out by the naked eye (see fig. 4). The anterior limbs of the H form the anterior or ventral cornua, while the posterior, which in the greater part of the cord are longer and thinner, are the posterior or dorsal cornua. At the tips of the latter is a lighter-coloured cap known as the substantia gelatinosa Rolandi. On each side of the H is a slighter projection, the lateral cornu, best marked in the thoracic region (see fig. 4).

The grey matter has different appearances in different regions of the cord, and in the cervical and lumbar enlargements, where the nerves to the limbs come off, the anterior horns are broadened

Histologically the grey matter is made up of neuroglia, medullated and non-medullated nerve fibres, and nerve cells (see Nervous System). The nerve cells are arranged in three main columns, ventral, intermedio-lateral and posterior vesicular The ventral cell column has the longest cells, and these are again subdivided into antero-mesial, antero-lateral, postero-lateral and central groups. The intermedio-lateral cell column is found in

the lateral horn of the thoracic region.

The posterior vesicular or Clarke's column is also largely confined to the thoracic region, and lies in the mesial part of the posterior cornu. It is the place to which the sensory fibres of the sympathetic system (visceral afferents) run. The white matter, as has been shown, surrounds the grey and passes across the middle line to form the white commissure, which lies in front of the grey. It is composed of neuroglia and medullated nerve fibres, which are arranged in definite tracts, although in a section of a healthy cord these tracts cannot be distinguished even with the microscope. They have been and are still being gradually mapped out by pathologists, physiologists and embryologists.

A sensory nerve on passing into the cord (fig. 3) through the posterior nerve root lies close to the mesial side of the posterior horn of grey matter, where most of it runs upward. The next root higher up takes the same position and pushes the former one toward the middle line, so that the lower nerve fibres occupy an Fig. 2.—DIAGRAM OF DORSAL AS-

area close to the postero-median PECT OF SPINAL CORD, SHOWING fissure known as the tract of CERVICAL AND LUMBAR SWELLINGS

Goll, while the higher lie more externally in the tract of Burdach. The greater part of each nerve sooner or later enters the grey matter and comes into close relation with the cells of Clarke's column. but some fibres run right up to the nucleus gracilis and cuneatus in the medulla (see Brain), while a few turn down and form a descending tract, which, in the upper part of the cord, is situated in the inner part of the tract of Burdach and is known as the comma tract, but lower down gradually shifts quite close to the postero-median fissure and forms the oval area of Flechsig. It will be obvious that both these tracts could not be seen in the same section, and that fig. 3 is only a diagrammatic outline of their position.

A few fibres of each sensory nerve ascend in a small area known as Lissauer's tract on the outer side of the posterior nerve roots, and eventually enter the substantia gelatinosa.

To the outer side of Lissauer's tract and lying close to the lateral surface of the cord is the direct cerebellar tract, the fibres of which ascend from the cells of Clarke's column to the cerebellum. As Clarke's column is only well developed in the thoracic region this tract obviously cannot go much lower.

In front of the last and also close to the lateral surface of the cord is another ascending tract, the tract of Gowers, or, as it is sometimes called, the lateral sensory fasciculus. It probably begins in the cells of the posterior horn, and runs up to join the fillet and also to reach the cerebellum through the superior cerebellar peduncle. The crossed pyramidal tract lies internal to the direct cerebellar tract, between it and the posterior cornu. It is the great motor tract by which the fibres coming from the Rolandic area of the cerebral cortex are brought into touch with the motor cells in

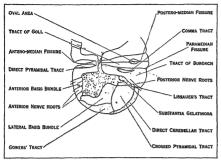

FIG. 3.—TRANSVERSE SECTION OF CORD SHOWING TWO MEDIAN FIS-SURES AND SCHEMATIC ARRANGEMENT OF COLUMNS OF FIBRES IN THE WHITE MATTER OF ONE HALF

the anterior cornu of the opposite side. This tract extends right down to the fourth sacral nerve.

In front of the crossed pyramidal tract is the lateral basis bundle, which probably consists of association fibres linking up different segments of the cord.

The anterior basis bundle lies in front and on the mesial side of the anterior cornu, and through it pass the anterior nerve roots. Like the lateral bundle it consists chiefly of association fibres, but it is continued up into the medulla as the posterior longitudinal bundle to the optic nuclei.

The direct pyramidal tract is a small bundle of the motor fibres from the Rolandic area, which, instead of crossing to the other side at the decussation of the pyramids in the medulla, runs down by the side of the antero-median fissure. Its fibres, however, keep on gradually crossing to the opposite side through the anterior white commissure of the cord, and by the time the mid-thoracic region is reached it has usually disappeared.

The roots of the spinal nerves in the upper part of the canal rise from the cord nearly opposite the points at which they emerge between the vertebrae, but the farther one passes down the higher the origin of each root becomes above its point of emergence. Consequently the lumbar and sacral nerves run a long way down from the lumbar enlargement to their spinal foramina and are enclosed in the dural and arachnoid sheaths to form a mass like a horse's tall, which is therefore known as the cauda equina.

Embryology.—The early development of the neural tube from the ectoderm is outlined in the article on the Brain. When the neural groove becomes a tube it is oval in section with a very large laterally compressed central canal (see fig. 5). The original ectodermal cells elongate and, radiating outward from the canal, are now known as spongioblasts, while the inner ends of some of them bear cilia and so the canal becomes ciliated. A number of round cells, known as germinal cells, now appear close to the central canal, except at the thin mid-dorsal and mid-ventral laminae (roofplate and floor-plate). From the division of these the primitive nerve cells or neuroblasts are formed and these later on migrate from the region of the canal and shoot out long processes—the axons. The permanent central canal of the cord was formerly said only to represent the ventral end of the large embryonic canal, the dorsal part being converted into a slit by the gradual closing in of its lateral walls, thus forming the postero-median fissure. A. Robinson, however, does not believe that the posterior fissure is any remnant of the central canal (Studies in Anatomy,

Owens College, 1891). Probably the fissure is formed partly by an infolding and partly from the original central canal. The antero-median fissure is caused by the ventral part of the cord growing on each side, but not in the mid-line where no germinal cells are

The anterior nerve roots are formed by the axons of the neuroblasts in the developing anterior cornua, but the posterior grow

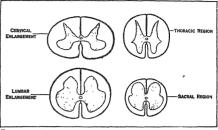

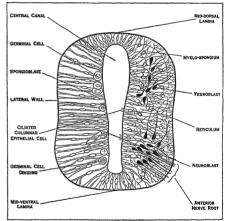

FIG. 4.—SECTIONS OF SPINAL CORD AT DIFFERENT LEVELS (2 X NAT SIZE)

into the cord from the posterior root ganglia (see Nerve: Spinal), and, as they grow, form the columns of Goll and Burdach.

In the embryo up to the fifth month there is little difference in the appearance of the grey and white matter of the cord, but at that time the fibres in the columns of Burdach acquire their medullary sheaths or white substance of Schwann, the fatty matter of which is probably abstracted from the blood. Very soon after these the basis bundles myelenate and then, in the sixth month, the columns of Goll. Next follow the direct cerebellar

tracts and, in the latter half of the eighth month the tracts of Gowers, while the fibres of the pyramidal and Lissauer's tracts do not gain their medullary sheaths until just before or after birth. At first the spinal cord extends as far as the last mesodermal somite, but neuroblasts are only formed as far as the first coccygeal somite, so that behind that the cord is non-nervous and degenerates later into the filum terminale. After the fourth month the nervous portion grows more slowly than the rest of the body

and so the long cauda equina and filum terminale are produced. At birth the lower limit of the cord is opposite the third lumbar vertebra, but in post-natal development it recedes still farther to the lower level of the first.

For further details see standard text books, e.g., Quain's Anatomy and J. P. McMurrich, Development of the Human Body

Comparative Anatomy.—In the Amphioxus there is little difference between spinal cord and brain; the former reaches the whole length of the body and is of uniform calibre. It encloses a central canal from which a dorsal fissure extends to the surface of the cord and it is composed of nerve fibres and nerve cells; most of the latter being grouped round the central canal or neurocoele, as they are in the human embryo. Some very large multipolar ganglion cells are present, and there are also large fibres known as giant fibres, the function of which is not clear.

When the reptiles are reached the cord shows slight enlargements in the regions of the limbs and these become more marked in birds and mammals.

In the lumbar region of birds the dorsal columns diverge and open up the central canal, converting it into a diamond-shaped space which is only roofed over by the membranes of the cord, and is known as the *sinus rhomboidalis*.

In all these lower vertebrates except the Anura (frogs and toads), the cord fills the whole length of the spinal canal, but in the higher mammals (Primates, Chiroptera and Insectivora) it grows less rapidly, and so the posterior part of the canal contains the cauda equina within its sheath of dura mater. In mammals below the anthropoid apes there are no direct pyramidal tracts in the cord, since the decussation of the pyramids in the medulla is complete. Moreover, the crossed tracts vary very much in their proportional size to the rest of the cord in different animals. In man, for example, they form IT-87% of the total cross area of the cord, in the mouse IT-47%. In the frog no pyramidal tract is found. It is obvious, therefore, that in the lower vertebrates the motor fibres of the cord are not so completely gathered into definite tracts as they are in man.

A good deal of interest has lately been taken in a nerve bundle which in the lower vertebrates runs through the centre of the central canal of the cord, and takes its origin in the optic reflex cells in close relation to the posterior commissure of the brain. More posteriorly (caudad) it probably acquires a connection with the most or cells of the cord and is looked upon as a means by which the muscles can be made to respond to the stimulus of light. It is known as Reissner's fibre, and its morphology and physiology have been studied most carefully in cyclostomes and fishes. It is said to be present in the mouse, but hitherto no trace of it has been found in man. It was discovered in 1860, but for forty years was looked upon as an artifact.

## PHYSIOLOGY

The spinal cord is but a part of the nervous organ which throughout the length of the body forms the meeting-place of the nerve-paths arriving from and issuing to all regions with which nerve fibres communicate. To gain a true point of view for understanding the working of the spinal cord one must refer to the general function of the nervous system in the bodily economy.

Relation to General Nervous System.—An animal of microscopic size may continue throughout its life to be constituted entirely by one single cell. Animals of larger bulk, although each begins its existence as a single cell, attain their development by the multiplication of the original single cell, so that from it there comes to be formed a coherent mass of cells very many millions in number. In these multicellular animals each of the constituent cells is a minute self-centred organism, individually born, leading its own life and destined for individual death. The corporate power of the complex animal is the sum of the powers of those

manifold individual existences, its cells. Of the agencies which integrate the complex animal, one of the most potent is nervous action A certain number of the unit cells composing the animal are specially differentiated from the rest to bind the whole together by nervous action. These specially differentiated cells are called "neurones." They constitute living threads along which waves of physico-chemical disturbance are transmitted to act as releasing forces for the energy in distant cells.

It is characteristic of this nervous system, the system of neurones, that, although ramifying far and wide through the body, it is a continuum from end to end. The peripheral nerves are formed of bundles of neurones lying side by side, but these, although packed close together, are strictly isolated one from another as conductors and remain isolated throughout the whole length of the nerve The points of functional nexus of the neurones one with another are confined to one region only of the whole system. All their conductive connections one with another take place solely in the central nervous mass which constitute the so-called central nervous system, a nervous organ extending axially along the length of the body midway between the body's lateral halves. Thither the neurones converge in vast numbers, those of each body segment converging to that fraction of the central organ which belongs to their body segment. The central nervous organ thus receiving these neurones is, where it lies in the head, called the brain, the rest of it is called in vertebrates the "spinal cord," in worms and arthropods the "nerve-cord." The central organ not only receives neurones which converge to it from outside, but many of its own neurones thrust out their conductive arms from it as nerve fibres carrying nervous influence outwards to regulate the activity of glands and muscles. In the vertebrates the ingoing neurones for each segment and similarly the outgoing neurone fibres are collected into a segmental nerve To the spinal cord these are each attached by two roots, one dorsal, consisting of the afferent fibres, the other ventral, consisting of the efferent fibres.

The Reflex .- The simplest complete reaction of the system is a reflex. There are many reflexes which are extremely complex, being built up of a number of simpler reflexes combined. A reflex is a reaction started by the environment acting as a stimulus upon some nerve which communicates the excitement to other nerves by connections with them in the central nervous organ. The excitement so generated and transmitted finally travels outward from the central organ by one or more of the efferent nerves and through these reaches muscles or glands producing in them its final effect. The muscles and glands are from this point of view termed effector organs. The reaction is therefore "reflected" from the central organ. The nerve structures which include its tra-jectory are spoken of as a nervous arc. The whole purpose of the central nervous organ is to bring afferent neurones into touch with efferent neurones. The whole purpose of reflex arcs is to bind one part of the organism to another part in such a way that what the environment is doing to the organism at one place may appropriately call forth or restrain movement or secretion in the muscles or glands wherever situated in the organism.

Receptor Cells .- There is one condition for the due performance of these reactions which is not provided by the nervous system itself. The afferent neurones are not in most cases so constituted as to be excitable themselves directly by the environment-for instance, they cannot be stimulated by light. Their amenability to the environment, their sensitization to environmental agencies, is effected by special cells adjunct to their peripheral ends. These cells form organs called receptors. They are delicately adapted to be stimulated by this or that particular agent and are classifiable into various species, so that each species is easily excited by a particular agent which is "adequate" for it, and is inexcitable or excitable only with difficulty by agencies of other kinds. Thus in the skin some receptors are adapted for mechanical stimuli (touch) and not for thermal stimuli, while others (cold spots, warm spots) are adapted for thermal stimuli and not for mechanical. As far as it is known each afferent neurone is connected with receptors of one species only. receptors thus confer upon the reflex arcs selective excitability

Each arc is thus tuned to respond to certain stimuli, while other arcs not having that kind of receptor do not respond. The receptors, therefore, while increasing the responsiveness of the organism to the environment, prevent confusion of reactions (incoordination) by limiting to particular stimuli a particular reaction

Proprioceptors.—The system of neurones is thus made accessible to the play of the external world acting on the body. And in addition to those receptors which are stimulated directly by the external world, are others lying within the mass of the organism itself, which are excitable by actions occurring in the organism itself. These are called proprioceptors. They are distributed preponderantly in the muscles and structures functionally adjunct to muscle, such as joints, ligaments, fasciae, etc. The reactions both passive and active induced in such motor structures, reflexly by environmental stimuli, tend therefore secondarily to be followed and accompanied by reflex reactions initiated from proprioceptors.

Conduction.-The process by which the excitement generated in the afferent neurone travels along the reflex arc is known as conduction. Conduction along afferent and efferent nerves differs in some important respects from that obtaining in the nerve centre, i e., in the piece of the central nervous system connecting the afferent nerve with the efferent nerve. In a nerve-trunk the excited state set up in it by a stimulus travels along its fibres as wave-like disturbance at a speed of about 100 metres per second, and does not alter in intensity or speed in its travel. A nerve-trunk when excited at some point along its length transmits the "impulse," i.e., the wave-like excited state in both directions. ie, both up and down each fibre, from the point stimulated. This is true whether the fibre is afferent or efferent. The speed of travel of the nervous impulse along the nerve-trunk is the same whether the nervous impulse is weak or intense. The nerve-trunk shows practically no delay in its response to an effective, even though weak, stimulus and its response ceases practically at once on cessation of the exciting stimulus. When excited by repeated brief stimuli the rhythm of the response corresponds closely with that of the stimuli, even when the frequency of the latter is as high as 500 per second. With momentary stimuli a response even so brief as 20 can be given by the nerve-trunk. Finally, nerve-trunk conduction is singularly resistant to fatigue, to impoverished blood supply, and to many drugs which powerfully affect reflex actions.

Through the central nervous organ the travel of the impulse exhibits departure from these features. Its intensity is liable to be altered in transit. Its time of transit is much longer than for a similar length of nerve-trunk. Its direction of transmission becomes polarized, that is, confined to one direction along the nervous path. To a strong stimulus the central reaction instead of being as brief as an impulse, may endure for a whole second or more. A stimulus not capable of evoking a response from a centre when applied once may by simple repetition become effective (temporal summation). It is in the grey matter that conduction differs in these respects from conduction in nerve-trunks. In the grey matter each afferent fibre breaks up into branching threadlets which ramify in various directions and terminate in close apposition with other neurones. The point of nexus of one neurone with another is termed the synapse. If synapsis occurs by contiguity and not homogeneous continuity, it is fair to suppose that at it the transmission of nervous impulses must be different from that observable in the homogeneous conducting threads of nerve fibres. The conduction must traverse something of the nature of a membrane.

Reflex Reactions.—When the spinal cord is severed at any point the reflex arcs of the portion of the body behind the transection are quite cut off from the rest of the nervous system in front, including the brain. The reflex reactions elicited from the thus isolated region cannot therefore be modified by the action of the higher nervous centres. In the head the local centres are overlaid by higher centres which cannot by any simple severance be separated from them. By studying, therefore, the powers of the cord behind a complete spinal transection we can obtain information as to the powers of the purely local or segmental reflex mechanisms.

The so-called "flexion-reflex" of the limb is one of the most accessible of the local reflex reactions which can thus be studied with an isolated portion of the spinal cord as its centre.

Let it be supposed that the limb observed is the hind limb. The three main joints of the limb are the hip, the knee and the ankle Each of these joints is provided with muscles which flex or bend it, and others which extend or straighten it. It is found that the reflex throws into contraction the flexor muscles of each of these joints. It matters little which of all the various afterent nerves of the limb is stimulated, whichever of these the afferent nerve may be, the centrifugal discharge goes to practically the same muscles, namely, always to the flexors of the joints.

Not only does the reflex action not discharge motor impulses into the nerves of the extensor muscles, but if the spinal cord happens to be discharging impulses into these nerves when the reflex is evoked this discharge is suppressed or diminished (inhibited). In this way the latter muscles are prevented from impeding the action of the contracting flexors. This inhibition prevents other reflexes from upsetting for the time being the due action of the flexion-reflex, for it renders the muscles opposing that reflex less accessible to motor discharge through the spinal cord whatever the quarter whence incitation to that discharge may come.

A feature of this reflex is its graded intensity A weak stimulus evokes in the flexor muscles a contraction which is weak and in the extensor muscles a relaxation which is slight. In the case of the muscle-fibre any strength of stimulus if sufficient to excite it at all excites the fibre totally and evokes its full contraction (Keith-Lucas) and this latter remains the same in amount so long as the mechanical and nutritive conditions of the fibre remain constant. Each muscle-fibre reacting on this "all-or-none" principle and each nerve-fibre similarly responding on that same principle (Kato), different amounts of contraction yielded by the muscle under different strengths of stimulation of its nerve signify differences simply in the number of muscle-fibres which the stimulus excites. In other words the weaker stimuli excite fewer of the nerve-fibres innervating the muscle. When the tension developed by the muscle, e.g., against a stiff spring, reaches the maximal obtainable from it, that fact tells us that all the muscle-fibres are then in contraction; when the tension development is less than maximal some of the muscle-fibres are not in action. A stimulus to the nerve which evokes maximal tension from the muscle is one which succeeds in exciting all the nerve-fibres innervating the muscle, and any stimulus which evokes less than maximal tension is leaving some of the nerve-fibres "idle."

The tension developed by a muscle under reflex excitation falls short of its maximal tension, even when the afferent nerve is stimulated maximally. The reflex activates a proportion only of the total aggregate of the muscle's fibres, and therefore a proportion only of the spinal motor neurones innervating the muscle. But within the range of the limit imposed by the maximal number of muscle-fibres which it can activate, the grading of the number activated in accordance with the grading of the strength of stimulation of the afferent nerve is very delicate, much more so than in the case of the motor nerve itself. The actual fractional proportion of the muscle's total aggregate of motor units which an afferent nerve, maximally stimulated, can activate, differs from one afferent nerve to another, and for the same afferent nerve in different experiments. A subconvulsive dose of strychnine raises the size of the fraction. The threshold value of stimulus for the reflex is usually higher than for the contraction of the muscle from the motor nerve. Spinal reflex action no more regards 'muscles" than does a motor centre of the cerebral cortex. Both ignore muscles as entities and have in view movements purely. A weak flexion-reflex activates a few fibres of each of the several flexor muscles of the limb. The reflex treats a complex composed from some (i.e., those of similar threshold for the particular afferent nerve) motor-units of hip-flexor, of knee-flexor and of ankle-flexor as functionally more homogeneous than is the total group of fibres composing any one of these muscles alone.

Reflex inhibition has its seat in the grey matter of the spinal centre. It acts at some point in the reflex arc up-stream from

the all-or-none motor unit (motor nerve-fibre with its group of hind limbs of the "spinal" frog assume an attitude which is reflex, muscle-fibres). The inhibitory reflex is like the excitatory capable of very delicate grading; its effect in diminishing or precluding this or that amount of an excitatory reflex is effected entirely by regulating the number of the motor units thrown out of action or kept out of action. Intensity of contraction or of relaxation is thus in both cases a question simply of number of motor-units reacting. The reflex centre continues discharging impulses for a certain time after its exciting stimulus has ceased. This afterdischarge succeeding a strong stimulus may persist even for several seconds.

Refractory Phase.-Besides characters common to all or many spinal reflexes certain spinal reflexes have features peculiar to themselves or exhibited by them in degrees not obvious in other reflexes One of these features is refractory phase. The scratchreflex exemplifies this. In the dog, cat and many other animals the hind limb often performs a rapid scratching movement, the foot being applied to the skin of the shoulder or neck as if to groom the hairy coat in that region. This movement is in the intact animal under control of the brain, and can be executed or desisted from at will. When certain of the higher centres in the brain have been destroyed, this scratching action occurs very readily and in an uncontrolled way. When the spinal cord has been severed in the neck this scratching movement of the hind limb can be elicited with regularity as a spinal reflex by merely rubbing the skin of the side of the neck or shoulder, or applying there a weak electric current to the skin. In this reflex the stimulus excites afferent nerves connected with the hairs in the skin and these convey impulses to the spinal centres in the neck or shoulder segments, and these in turn discharge impulses into nerve fibres entirely intraspinal passing backward along the cord to reach motor centres in the hind limb region. These motor centres in turn discharge centrifugal impulses into the muscles of the hind limb of the same side of the body as the shoulder which is the seat of irritation. The motor discharge is peculiar in that it causes the muscles of the hind limb to contract rhythmically at a rate of about four contractions per second, and the discharge is peculiar further in that it excites the flexor and extensor muscles of the joints alternately so that at the hip for instance the limb is alternately flexed and extended, each single phase of the movement lasting about an eighth of a second. Now this rhythmic discharge remains the same in rate whether the exciting stimulus applied to the skin be continuous or one of many various rates of repetition. Evidently at some point in the reflex arc there is a mechanism which after reacting to the impulses reaching it remains for a certain brief part of a second unresponsive, and then becomes once more for a brief period responsive, and so on. And this phasic alternation of excitability and inexcitability repeats itself throughout the continuance of the reflex. The phase of inexcitability is termed the refractory phase. Its seat lies in the spinal centre. A similar element almost certainly forms part of the co-ordinating mechanism for many other cyclic reflexes, including those of the stepping of the limbs, the movement of the jaw in mastication, the action of the eyelids in blinking, and perhaps the respiratory movements of the chest and larynx.

Fatigue.-Nerve trunks do not easily tire out under stimulation even most prolonged. Reflex actions on the other hand relatively soon tire. Some are more resistant, however, than are others. The flexion-reflex may be continued for ten minutes at a time. As a reflex tires, the muscular contraction which it causes tends to become less intense and less steady. The relatively rapid onset of fatigue in reflexes is counterbalanced by speedy recovery in repose. A long flexion-reflex, when from fatigue it has become weak, tremulous and irregular, will recommence after 30 seconds' repose with almost the same vigour and steadiness as if it had not recently been tired out.

The natural movements to which the artificially provoked reflexes seem to correspond do not demand prolonged motor activity, or when they do, demand it in rhythmic repetition with intervening pauses which allow repose.

Reflex Postures.-But there are certain reflexes which do persist for long periods at a time. These are reflex postures. The

for it ceases on severance of the afferent spinal roots. This attitude is one of flexion at hip, knee and ankle, resembling the wellknown natural posture of the frog as it squats when quiet in the tank. Similarly in the "decerebrate" dog or cat certain muscles, e.g., the limb extensors, exhibit a persistent contraction. These tonic reflexes are related to attitudes. In the dog and cat they are exhibited by those muscles whose action antagonizes gravity in postures which are usual in the animal, thus the extensors of the knee and hip and shoulder and elbow are in tonic contraction during standing. The postural contraction is accompanied by electrical "action currents" like those of other contraction, though weak and indicative of self-smothering from the rhythms being asynchronous in the contributory fibre-groups. The postural contraction of the extensor muscles in the maintenance of the erect posture is traceable to a reflex, called the stretch-reflex. A stretch, e.g., by a pull upon the tendon, lengthening the muscle by even so little as 1%, excites reflex contraction of some of its fibres. The passive stretch is a mechanical stimulus to some of the proprioceptive organs (perhaps the muscle-spindles) in the muscle. The reflex is therefore unobtainable when the afferent nerve-fibres of the muscle itself have been severed. The essential centre for the stretch-reflex is spinal, but mid-brain and cerebellar centres much reinforce it. In the erect posture the head, neck, tail and jaw would droop and the limbs fold up under their own weight and that of superincumbent parts, were not the "antigravity muscles checked from yielding by the stretch-reflex which their own passive yield induces in themselves. Hence the reflexly maintained "standing" is a multiple stretch-reflex. Considerable latitude of actual pose is allowed to the individual parts because each muscle involved acts for itself and develops and regulates its own stretch-reflex.

Characteristic of reflex postural contraction is its continuance for long spells at a time without obvious fatigue. Attempts are uniformly unsuccessful to reproduce this feature by electrical stimulation of afferent nerves or of the muscle's motor nerve. The suggestion has therefore been made that the postural contraction of muscle is due to a different process in the muscle-fibre from that of the ordinary contraction executing movements and so easily and often studied under electrical stimulation in the laboratory. Forbes, however, has offered the satisfactory explanation that the postural contraction while the same process as that of ordinary reflex and other contraction involves usually relatively few motor units at a time and these as they fatigue, are replaced by others. The stretch which is the essential stimulus is automatically shifted to fresh motor-units so soon as those already in operation begin to yield and give out. Grafted, as it were, upon the reflex maintenance of the erect-posture are reflexes of locomotion which are also certainly spinal in essence, and essentially proprioceptive. The hind-limbs of the dog, after severance of the cord in the thoracic region, begin to step when released from the ground. Their stepping will go on sometimes quicker and sometimes slower for long periods at a time. Kinematograph analysis of this spinal stepping shows that it is identical with normal stepping except for a slight flexional yield when the limb is vertically on the ground in the normal step. Passively supported mid-flexion of knee and hip even of one hind limb alone at once causes the spinal reflex stepping to cease, in both limbs usually. The proprioceptive stimulus of the spinal stepping may therefore be the passive stretching of the hip and knee-flexor. From observations on stepping under narcosis Graham Brown regards the essential factor in "spinal" stepping to be the intrinsic activity of a "spinal stepping" centre or "centres." Certainly it is not uncommon for an extensor muscle of the limb in isolated attachment to the myograph and after its own afferent nerve fibres have been wholly destroyed and after all the other muscles of the limb have been put out of play by excision of nerve-section to start stepping on its own accord in the bulbospinal preparation. Skin stimuli, for instance, the contact of the sole with the ground. are not necessary for the reflex stepping. On the other hand the ground pressure against the toe pads and plantar cushion seems an important factor in the gallop-indeed the sudden brief though strong and almost simultaneous extension of all four limbs in the gallop can in the spinal animal be evoked by pressure simulating the ground pressure, and when applied even to one hind foot only.

The eyeballs are eminently organs which, the gaze being a posture, employ active postures throughout the waking day. The proprioception of the neck-muscles excites from the cervical spinal cord reflex influences acting on the nerves of the eyeball muscles. An instance is: turning of the neck toward one side. Or again, a clockwise partial rotation of the neck round its long axis excites from the neck proprioceptor a compensatory anti-clockwise rotation of the eyeballs. These reflex postures of the eyeballs are sometimes called compensatory, because they tend to keep truly vertical the vertical of the retina despite displacements of the head by the movements of the neck.

It may be mentioned here that the spinal and the bulbospinal animal (cat) although its composite stretch-reflex enables it when placed in the erect posture to maintain that attitude, even for hours at a time, is yet not capable of assuming that posture when laid, for instance, on its side. But when the mid-brain is retained in addition to hind-brain and cord the animal has that power of righting itself. These righting reflexes are likewise postural and largely evoked by the otolith organs. Although not truly spinal reflexes their field of nervous operation overruns into the spinal cord.

The Spinal Reflex Arcs of the Hind Limb.—When the skin of the limb is stimulated the flexion-reflex already described is evoked. The reflex is excited by nocuous stimuli such as a prick or squeeze applied to the skin anywhere in the limb, but most easily when applied to the foot. The reflex flexion of the ipsilateral hind limb is commonly accompanied by reflex extension of the opposite hind limb.

In the dog and cat extension of the ipsilateral hind limb can, however, be excited by stimulation of the skin in three limited regions. One of these is the sole of the foot; smooth pressure between the pads excites a strong brief extension. This is called the extensor thrust. It is accompanied by a similar sudden brief extension of all three other limbs. This reflex may be related to the action of galloping, and the pressure which excites resembles that which the weight of the body bears on the pads against the ground

The two other regions are the skin of the front of the groin supplied by the crural branch of the genito-crural nerve, and the skin just below and mesial to the buttock. These always excite the extensor muscles, not the flexors. They may be concerned with sexual acts.

Reflexes of the Fore Limb.—The ipsilateral reflex is flexion at shoulder, elbow and wrist. The contralateral fore limb at the same time is extended at shoulder, elbow and wrist.

The Scratch Reflex.—The area from which it can be excited extends from the ear to the loin. Each of these reflexes is a coordinate reaction. It is seen, therefore, that through the medium of the spinal cord the body behind the head has at command a certain number of reflexes and that each of these manages the skeletal musculature in a co-ordinate way. The muscles worked by these several reflexes are to a large extent common to them all. Some resemble one another in regard to their action upon a particular muscle. Some act in opposite ways upon a particular nuscle. In order to follow the co-ordination effected by the spinal cord we have to turn to a certain feature in the scheme of construction of the nervous system. This feature embodies what is termed the principle of the common path.

Interaction Between Reflexes.—At the commencement of every reflex-arc is a receptive neurone extending from the receptive surface to the central nervous organ. This neurone forms the sole avenue which impulses generated at its receptive point can use whithersoever be their destination. This neurone is therefore a path exclusive to the impulses generated at its own receptive point, and other receptive points than its own cannot employ it. A single receptive point may play reflexly upon quite a number of different effector organs. It may be connected

through its reflex path with many muscles and glands in many different regions. Yet all its reflex arcs spring from the one single shank or stem, i.e., from the one afferent neurone which conducts from the receptive point at the periphery into the central nervous organ.

But at the termination of every reflex arc we find a final neurone, the ultimate conductive link to an effector organ (muscle or gland). This last link in the chain, e.g., the motor neurone, differs obviously in one important respect from the first link of the chain. It does not subserve exclusively impulses generated at one single receptive source, but receives impulses from many receptive sources situate in many and various regions of the body. It is the sole path which all impulses, no matter whence they come, must travel if they are to act on the muscle fibres to which it leads.

Therefore, while the receptive neurone forms a private path exclusively serving impulses of one source only, the final or efferent neurone is, so to say, a public path common to impulses arising at any of many sources of reception. A receptive field, e.g., an area of skin, is analysable into receptive points. One and the same effector organ stands in reflex connection not only with many individual points, but even with many various receptive fields. Reflexes generated in manifold sense-organs can pour their influence into one and the same muscle. Thus a limb muscle is the terminus ad quem of many reflex arcs arising in many various parts of the body. Its motor nerve is a path common to all the reflex arcs which reach that muscle.

Reflex arcs show, therefore, the general features that the initial neurone of each is a private path exclusively belonging to a single receptive point (or small group of points); and that finally the arcs embouch into a path leading to an effector organ; and that their final path is common to all receptive points wheresoever they may lie in the body, so long as they have connection with the effector organ in question. Before finally converging upon the motor neurone the arcs converge to some degree. Their private paths embouch upon internuncial paths common in various degrees to groups of private paths. The terminal path may, to distinguish it from internuncial common paths, be called the final common path. The motor nerve to a muscle is a collection of final common paths.

Certain consequences result from this arrangement. One of these is the preclusion of essential qualitative difference between nerve-impulses arising in different afferent nerves. If two conductors have a tract in common there can hardly be essential qualitative difference between their modes of conduction.

A second consequence is that each receptor being dependent for final communication with its effector organ upon a path not exclusively its own but common to it with certain other receptors, such nexus necessitates successive and not simultaneous use of the common path by various receptors using it to different or opposed effect.

In the simultaneous correlation of reflexes some reflexes combine harmoniously, being reactions that mutually reinforce. These may be termed allied reflexes, and the neutral arcs which they employ allied arcs. On the other hand, some reflexes, as mentioned above, are antagonistic one to another and incompatible. These do not mutually reinforce, but stand to each other in inhibitory relation. One of them inhibits the other.

Allied Reflexes.—What happens when trains of impulses, travelling by convergent afferent arcs, meet at the same "common path?" With convergent reflexes which are "allied" in the above sense, this case must be one of extremely frequent occurrence and the management of the interaction between the convergent streams of impulses must be a fundamental factor in nervous co-ordination. The afferent path A embouches upon the intraspinal motor neurones of the knee-flexor and can activate 75% of them. The afferent path B embouches also upon the motor neurones of the same muscle and can activate 75% of them. When the muscle is reflexly contracting to A with a tension 75% of that of the muscle's maximal contraction, stimulation of B is added. The contraction tension in result rises to 85% of the maximal. The inference is that for 65% of the total motor units

of the muscle the excitation from A acts upon the same motor units as would that from B. In other words 65% of the total aggregate of the motor units of the muscle are common to A and to B. The stream of impulses arriving at these common motor-units from B when A's stream is already activating them leaves their activity unchanged, failing either to increase or to diminish it. A's stream, which is engaging them, precludes B's stream from engaging them. This is termed occlusion. We may turn from the case of the group to that of the single individual unit. Suppose a to be a train of impulses reaching a central terminal of path A and impinging upon a motor-unit  $\mu$  and activating it. Suppose  $\beta$  similarly a train impinging by one of path B's terminals upon the same motor unit µ already activated by a It has been argued that the resultant response of  $\mu$  to the double series of impulses impinging on it will show interference and interruption and unsteadiness from "inhibition," the impulses generated by the one train interfering with those generated by the other owing to the refractory phase following in the wake of each impulse. Experiment fails to substantiate such unsteadiness or other evidence of "interference inhibition" even when the impulse trains are each of them at 180 p. sec. Experiment in fact finds the reverse; the resultant contraction being steadier and more durable under the concurrent excitation of A and B than under either alone. An important kind of observation is the following, since it shows clearly that, against the interference view above, "occlusion" is not inhibition. An afferent A activates 50% of a given muscle's motor units. An afferent B activates a still larger percentage of the muscle's motor units. When afferent B is already activating the muscle the stimulation of A causes no outward result on the muscle, but if B's stimulus be then withdrawn A's continuing, the contraction at once falls to and remains at 50% of maximal. A's activation was occluded by B's already existent one, but there was no inhibition. A's activation was occluded throughout the large field amounting to 50% of the total aggregate of the motor units. Yet that not a single motor unit was inhibited, has been experimentally established by taking for B one of the relatively rare afferents which activate 100% of the muscle. Since B is then activating every motor unit it cannot be supposed that lack of A's effect when A is concurrently stimulated is due to inhibition of A's 50% of the motor units; for that would suppose those motor units to be at one and the same time both active and inhibited. The mutual support that the two trains yield each other in the actually observed result argues the immediate replacement of B's effect by A's when B's lapses or intermits: and vice versa. That this would be so is borne out by other observations. Where, during the concurrence of A and B, A's effect has been occluding B from activating, on abruptly ceasing to stimulate A, so that B remains under stimulation alone, B which has till then been ineffective owing to occlusion, at once appears as effective and without hesitation or pause replaces that of A step for step as A's after-discharge subsides. The final common path under this competition of allied arcs is comparable with a telephone line already "busy" for one subscriber and for that time "engaged" and non-available to other subscribers. The action of the principle of the final common path may be instanced in regard to "allied arcs" in the scratch-reflex as follows. If, while the scratch-reflex is being elicited from a skin point at the shoulder, a second point distant romm, from the other point but also in the receptive field of skin, be stimulated, the stimulation at this second point favours the reaction from the first point. This is well seen when the stimulus at each point is of subminimal intensity. The two stimuli, though each unable separately to invoke the reflex, yet do so when applied both at the same time. The "receptive field" of a reflex is really the common area of commencement of a number of allied arcs.

Antagonistic Reflexes.—But not all reflexes connected to one and the same common final path stand to one another in the relation of "allied reflexes." Suppose during the scratch-reflex a stimulus be applied to the foot not of the scratching side, but of the opposite side. The left leg, which is executing the scratch-reflex in response to stimulation of the left shoulder skin is cut short in its movement by the stimulation of the right foot. al-

though the stimulus at the shoulder to provoke the scratch movement is maintained unaltered all the time. The stimulus to the right foot will temporarily interrupt a scratch-reflex, or will cut it short or will delay its onset; which it does of these depends on the time-relations of the stimuli. The inhibition of the scratchreflex occurs sometimes when the contraction of the muscles innervated by the reflex conflicting with it is very slight. There is interference between the two reflexes and the one is inhibited by the other.

The reflex from the right foot evokes at the opposite (left) knee extension; in doing this it causes steady excitation of extensor neurones of that knee and steadily inhibits the flexor neurones. But the scratch-reflex causes rhythmic excitation of the flexor neurones. Therefore these flexor neurones in this conflict lie as a final common path under the influence of two antagonistic reflexes, one of which would excite them to rhythmical discharge four times a second, while the other would continually repress all discharge in them.

In all these forms of interference there is a competition, as it were, between the excitatory stimulus used for the one reflex and the excitatory stimulus for the other. Both stimuli are in progress together, and the one in taking effect precludes the other's taking effect as far as the final common path is concerned.

Again, if, while stimulation of the skin of the shoulder is evoking the scratch-reflex, the skin of the hind foot of the same side is stimulated, the scratching may be arrested. Stimulation of the skin of the hind foot by any of various stimuli that have the character of threatening the part with damage causes the leg to be flexed, drawing the foot up by steady maintained contraction of the flexors of the ankle, knee and hip. Here, therefore, there is an arc which embouches into a final path, common to it and to the scratch-reflex arc; both these arcs employ the same effector organ, namely, the knee-flexor, and employ it by the common medium of the final path FC. But though the channels for both reflexes embouch upon the same final common path, the excitatory flexor effect specific to each differs strikingly in the two cases. In the scratch-reflex the flexor effect is an intermittent effect; in the noci-ceptive flexion-reflex the flexor effect is steady and maintained. The scratch-reflex is set aside by that of the noci-ceptive arc from the homonymous foot.

The stimulation which previously sufficed to provoke the scratch-reflex is no longer effective, though it is continued all time. But when the stimulation of the foot is discontinued the scratch-reflex returns. In that respect, although there is no enforced inactivity, there is an interference which is tantamount to, if not the same thing as, inhibition. Though there is no cessation of activity in the motor neurone one form of activity that was being impressed upon it is cut short and another takes its place. A stimulation of the foot too weak to cause more than a minimal reflex will often completely suffice to interrupt, or cut short, or prevent onset of, the scratch-reflex

The kernel of the interference between the homonymous flexion-reflex and the scratch-reflex is that both employ the same final common path FC to different effect—just as in the interference between the crossed extension-reflex and the scratch-reflex. Evidently, the homonymous flexion-reflex and the crossed extension-reflex both use the same final common path FC. And they use it to different effect. The motor neurone to the flexor of the knee being taken as a representative of the final common path, the homonymous flexion-reflex inhibits it from discharging. Hence if, while the direct flexion-reflex is in progress, the crossed foot is stimulated, the reflex of the knee-flexor is inhibited. The crossed extension reflex therefore inhibits not only the scratch-reflex, but also the homonymous flexion-reflex.

Further, in all these interferences between reflexes the direction taken by the inhibition is reversible. Thus, the scratch-reflex is not only liable to be inhibited by, but is itself able to inhibit either the homonymous flexion-reflex or the crossed extension-reflex; the homonymous flexion-reflex is not only capable of being inhibited by the crossed extension-reflex, but conversely in its turn can inhibit the crossed extension-reflex. These interferences are therefore reversible in direction. Certain conditions

determine which reflex among two or more competing ones shall mere repose of the reflex centre, the repose so recruiting the obtain mastery over the final common path and thus obtain centre as to strengthen its subsequent action. But a similar expression.

Here of the reflex centre, the repose so recruiting the centre as to strengthen its subsequent action. But a similar of the reflex centre, the repose so recruiting the obtain mastery over the final common path and thus obtain centre as to strengthen its subsequent action. But a similar centre as to strengthen its subsequent action.

As to the intimate nature of the mechanism which thus, by summation or by interference, gives co-ordination where neurones converge upon a common path, it is difficult to surmise. In the central nervous system of vertebrates, afferent neurones A and B in their convergence toward and impingement upon another neurone Z, towards which they conduct, do not make any lateral connection directly one with the other—at least, there seems no clear evidence that they do. It seems, then, that the only structural link between A and B is neurone Z itself. Z itself should therefore be the field of coalition of A and B if they transmit "allied" reflexes.

Factors Determining the Sequence.—The formation of a common path from tributary converging afferent arcs is important because it gives a co-ordinate mechanism. There the dominant action of one afferent arc, or set of allied arcs in condominium, is subject to supersession by another afferent arc, or set of allied arcs, and the supersession normally occurs with-

out intercurrent confusion.

Whatever be the nature of the physiological process occurring between the competing reflexes for dominance over the common path, the issue of their competition, namely, the determination of which one of the competing arcs shall for the time being reign over the common path, is largely conditioned by four factors. These are spinal induction, relative fatigue, relative intensity of stimulus, and the functional species of the reflex.

r. Induction occurs in two forms, one of which has been named immediate induction. The stimulus which excites a reflex tends by central spread to facilitate and lower the threshold for reflexes allied to that which it particularly excites. A constellation of reflexes thus tends to be formed which reinforce each other, so that a reflex figure results. If the prepotent stimulus shifts, allied arcs are by the induction particularly prepared to be responsive to it or to a similar stimulus.

Immediate induction only occurs between allied reflexes. Its tendency in the competition between afferent arcs is to fortify the reflex just established, or, if transition occur, to favour transition to an allied reflex. Immediate induction seems to obtain with highest intensity at the outset of a reflex, or at least near its commencement.

The other form of spinal induction is successive induction. It is in several ways the reverse of the preceding. If the crossed-extension reflex of the limb of the "spinal" dog be elicited at regular intervals, say once a minute, by a carefully adjusted electrical stimulus of defined duration and intensity, the resulting reflex movements are repeated each time with much constancy of character, amplitude and duration. If in one of the intervals a strong prolonged (e.g., 30") flexion-reflex is reduced from the limb yielding the extensor-reflex movement, the latter reflex is found intensified after the intercurrent flexionreflex. The intercalated flexion-reflex lowers the threshold for the aftercoming extension-reflexes, and especially increases their after-discharge. This effect may endure, progressively diminishing, through four or five minutes, as tested by the extensor reflexes at successive intervals. Now, as we have seen, during the flexion-reflex the extensor arcs were inhibited: after the flexionreflex these arcs are in this case evidently in a phase of exalted excitability. The phenomenon presents obvious analogy to visual contrast. The exaltation after-effect may ensue with such intensity that simple discontinuance of the stimulus maintaining one reflex is immediately followed by "spontaneous" appearance of the antagonistic reflex.

The so-called "mark-time" reflex of the "spinal" dog is an alternating stepping movement of the hind limbs which occurs on holding the animal up so that its limbs hang pendent. It can be inhibited by stimulating the skin of the tail. On cessation of that stimulus the stepping movement sets in more vigorously and at quicker rate than before. This after-increase might be explicable in either of two ways. It might be due to the

mere repose of the reflex centre, the repose so recruiting the centre as to strengthen its subsequent action. But a similar period of repose obtained by simply supporting one limb—which causes cessation of the reflex in both limbs, the stimulus being stretch of the hip-flexors under gravity—is not followed by after-increase of the reflex, or the after-increase might result from the inhibition being followed by a rebound to super-activity. This latter seems to be the case. The after-increase occurs even when both hind limbs are passively lifted from below during the whole duration of the inhibitory stimulus applied to the tail. And the reflex inhibition of the knee-extensor by stimulation of the central end of its own nerve is followed by marked rebound to superactivity of the extensor itself Again, the knee jerk, after being inhibited by stimulation of the hamstring nerve, is more brisk than before the inhibition.

By virtue of this spinal contrast, therefore, the extensionreflex predisposes to and may actually induce a flexion-reflex, and conversely the flexion-reflex predisposes to and may actually induce an extension-reflex. This process is qualified to play a part in linking reflexes together in alternating sequence

Much of the reflex action of the limb that can be studied in the "spinal" dog bears the character of locomotion. This has been shown recently with particular clearness by the observations of Phillipson. In the stepping of the limb the flexion that raises the foot and carries it clear of the ground prepares the antagonistic arcs of extension, and, so to say, sensitizes them to respond later in their turn by the supporting and propulsive extension of the limb necessary for progression. The reflex "stepping" of the "spinal" dog proceeds without an external skin stimulus: it will continue when the dog is held in the air. The cat walks well when all four feet are anæsthetized.

A reflex movement must generate in its progress a number of further stimuli and throw up a shower of centripetal impulses from the moving muscles and joints into the spinal cord. Squeezing of muscles and stimulation of their afferent nerves and those of joints, etc., elicit reflexes. The primary reflex movement might be expected, therefore, of itself to initiate further reflex movement, and that secondarily to initiate further still, and so on Yet on cessation of the external stimulus to the foot in the flexion-reflex the whole reflex comes usually at once to an end. The scratch-reflex, even when violently provoked, ceases usually within two seconds of the discontinuance of the external stimulus that provoked it. We have as yet no satisfactory explanation of this

2. Another condition influencing the issue of competition between reflexes of different sources for possession of one and the same final common path is fatigue. A spinal reflex under continuous excitation or frequent repetition becomes weaker, and may cease altogether. This decline is progressive, and takes place earlier in some kinds of reflexes than it does in others. In the "spinal" dog the scratch-reflex under ordinary circumstances tires much more rapidly than does the flexion-reflex.

A reflex as it tires shows other changes besides decline in amplitude of contraction. Thus in the flexion-reflex, the original steadiness of the contraction decreases; it becomes tremulous, and the tremor becomes progressively more marked and more irregular. Finally, an irregular phasic tremor of the muscles is all that remains. It is not the flexor muscles themselves which tire out, for these, when under fatigue of the flexion-reflex contract no longer for that reflex, contract in response to the scratch-reflex which also employs them.

Similar results are furnished by the scratch-reflex, with certain differences in accord with the peculiar character of its individual charge. One of these latter is the feature that the individual beats of the scratch-reflex usually become slower and follow each other at slower frequency. Also the beats, instead of remaining fairly regular in amplitude and frequency, tend to succeed in somewhat regular groups. The beats may disappear altogether for a short time, and then for a short time reappear.

When the scratch-reflex elicited from a spot of skin is fatigued, the fatigue holds for that spot, but does not implicate the reflex as obtained from the surrounding skin. The reflex is, when tired out to stimuli at that spot, easily obtainable by stimulation two or

more centimetres away.

The local fatigue of a spinal reflex seems to be recovered from with remarkable speed. A few seconds' remission of the stimulus suffices for marked though incomplete restoration of the reaction. Fatigue seems a process elaborated and preserved in the selective evolution of the neural machinery. One obvious use attaching to it is the prevention of the too prolonged continuous use of a common path by any one receptor It precludes one receptor from occupying for long periods an effector organ to the exclusion of all other receptors. It prevents long continuous possession of a common path by any one reflex of considerable intensity. It favours the receptors taking turn about It helps to ensure serial variety of reaction. The organism, to be successful in a million-sided environment, must in its reaction be many sided Were it not for such socalled fatigue, an organism might, in regard to its receptivity, develop an eye, or an ear, or a mouth, or a hand or leg, but it would hardly develop the marvellous congeries of all those various senseorgans which it is actually found to possess.

The final efferent-root neurone forms the instrument for many different reflex arcs and acts. It is responsive to them in various rhythms and in various grades of intensity. In accordance with this, it seems from experimental evidence to be relatively inde-

fatigable.

3 In the transition from one reflex to another a final common path changes hands and passes from one master to another. A fresh set of afferent arcs becomes dominant on the supersession of one reflex by the next. Of all the conditions determining which one of competing reflexes shall for the time being reign over a final common path, the intensity of reaction of the afferent arc itself relatively to that of its rivals is probably the most powerful. An afferent arc that strongly stimulates is caeteris paribus more likely to capture the common path than is one excited feebly. A stimulus can only establish its reflex and inhibit an opposed one if it have intensity. This explains why, in order to produce examples of spinal inhibition, recourse has so frequently been made in past times to strong stimuli. A strong stimulus will inhibit a reflex in progress although a weak one will fail. Thus in inhibition of micturition in the "spinal" dog a forcible squeeze of the tail will do it, but not a weak squeeze. So, likewise, any condition which raises the excitability and responsiveness of a nervous arc will give it power to inhibit other reflexes, just as it would if it were excited by a strong stimulus.

Crossed reflexes are usually less easy to provoke, less reliable of obtainment, and less intense than are direct reflexes. Consequently we find crossed reflexes usually more easily inhibited and replaced by direct reflexes than are these latter by those former. Thus the crossed stepping-reflex is easily replaced by the scratch-reflex, though its stimulus be continued all the time, and though the scratch-reflex itself is not a very potent reflex. But the reverse can occur with suitably adjusted intensity of stimuli.

Again, the flexion-reflex of the dog's leg is, when fully developed, accompanied by extension in the opposite leg. This crossed extensor movement, though often very vigorous, may be considered as an accessory and weaker part of the whole reflex, of which the prominent part is flexion of the homonymous limb. When the flexion-reflex is elicitable poorly, as, for instance, in spinal shock or under fatigue or weak excitation, the crossed extension does not appear. But, where the flexion-reflex is well developed, if not merely one but both feet be stimulated simultaneously with stimuli of fairly equal intensity, steady flexion at knee, hip and ankle results in both limbs, and extension occurs in neither limb. The contralateral part of each reflex is inhibited by the homolateral flexion of each reflex. In other words, the more intense part of each reflex obtains possession of the final common paths at the expense of the less intense portion of the reflex. But if the intensity of the stimuli applied to the right and left feet be not closely enough balanced, the crossed extension of the reflex excited by the stronger stimulus is found to exclude even the homonymous flexion that the weaker stimulus should and would otherwise evoke from the leg to which it is applied.

It was pointed out above that in a number of cases the transference of control of the final common path FC from one afferent

arc to another is reversible. The direction of the transference can caeteris paribus be easily governed by making the stimulation of this receptor or that receptor the more intense. A factor largely determining whether a reflex succeed another or not is therefore intensity of stimulus.

4. A fourth main determinant for the issue of the conflict between rival reflexes seems the functional species of the reflexes. Reflexes initiated from a species of receptor apparatus that may be termed noci-ceptive appear to dominate particularly the majority of the final common paths issuing from the spinal cord. In the simpler sensations we experience from various kinds of stimuli applied to our skin there can be distinguished those of touch, of cold, of warmth and of pain. The pain ending may be regarded as adapted to a whole group of excitants, a group of excitants which has in relation to the organism one feature common to all its components, namely, a nocuous character.

With its liability to various kinds of mechanical and other damage, in a world beset with dangers amid which the individual and species have to win their way in the struggle for existence, we may regard nocuous stimuli as part of a normal state of affairs. The skin has evolved a specific sense of its own injuries. As psychical adjunct to the reactions of that apparatus we find a strong displeasurable effective quality in the sensations they evoke. may be a means for branding upon memory, of however rudimentary a kind, a feeling from past events that have been perilously critical for the existence of the individuals of the species. In other words, if we admit that damage to such an exposed sentient organ as the skin must in the evolutionary history of animal life have been sufficiently frequent in relation to its importance, then the existence of a specific set of nerves for skin-pain seems to offer no genetic difficulty, any more than does the clotting of blood or innate immunity to certain diseases. That these nerve-endings constitute a distinct species is argued by their all evoking not only the same species of sensation, but the same species of reflex movement as regards "purpose," intensity, resistance to "shock," etc. And their evolution may well have been unaccompanied by evolution of any specialized end-organ, since the naked free nerveendings would better suit the wide and peculiar range of stimuli, reaction to which is in this case required. A low threshold was not required because the stimuli were all intense, intensity constituting their harmfulness; but response to a wide range of stimuli of different kinds was required, because harm might come in various forms. That responsive range is supplied by naked nerve itself, and would be cramped by the specialization of an end-organ. Hence these nerve-endings remained free.

It is those areas, stimulation of which, as judged by analogy, can excite pain most intensely, and it is those stimuli which, as judged by analogy, are most fitted to excite pain which, as a general rule, excite in the "spinal" animal-where pain is of course non-existent-the prepotent reflexes. The nervous arcs of pain-nerves, broadly speaking, dominate the spinal centres in peculiar degree. Pain is thus the psychical adjunct of an imperative protective reflex. It is preferable, however, since into the merely spinal and reflex aspect of the reaction of these nerves no sensation of any kind can be shown to enter, to avoid the term "pain-nerves." Remembering that the feature common to all this group of stimuli is that they threaten or actually commit damage to the tissue to which they are applied, a convenient term for application to them is nocuous. In that case what from the point of view of sense are cutaneous pain-nerves are from the point of view of reflex-action conveniently termed noci-ceptive nerves.

In the competition between reflexes the noci-ceptive as a rule dominate with peculiar certainty and facility. This explains why such stimuli have been so much used to evoke reflexes in the spinal frog, and why, judging from them, such "fatality" belongs to spinal reflexes.

One and the same skin surface will in the hind limb of the spinal dog evoke one or other of two diametrically different reflexes according as the mechanical stimulus applied be of noxious quality or not, a harmful insult or a harmless touch. A needle-prick to the planta causes invariably the drawing up of the limb—the flexion-reflex. A harmless smooth contact, on the other hand,

causes extension-the extensor-thrust above described This flexion is therefore a noci-ceptive reflex. But the scratch-reflex-which is so readily evoked by simple light irritation of the skin of the shoulder-is relatively mildly noci-ceptive. When the scratchreflex and the flexion-reflex are in competition for the final neurone common to them, the flexion-reflex more easily dispossesses the scratch-reflex from the final neurone than does the scratch-reflex the flexion-reflex. If both reflexes are fresh, and the stimuli used are such as, when employed separately, evoke their reflexes respectively with some intensity, in my experience it is the flexionreflex that is usually prepotent. Yet if, while the flexion-reflex is being moderately evoked by an appropriate stimulus of weak intensity, a strong stimulus suitable for producing the scratch-reflex is applied, the steady flexion due to the flexion-reflex is replaced by the rhythmic scratching movement of the scratch-reflex, and this occurs though the stimulus for the flexion-reflex is maintained unaltered. When the stimulus producing the scratch is discontinued the flexion-reflex reappears as before.

In decerebrate rigidity, where a tonic reflex is maintaining contraction in the extensor muscles of the knee, stimulation of the noci-ceptive arcs of the limb easily breaks down that reflex. The noci-ceptive reflex dominates the motor neurone previously held in activity by the postural reflex. And noci-ceptive reflexes are relatively little depressed by "spinal shock."

Besides those receptors attuned to react to direct noxa, the skin has others, concerned likewise with functions of vital importance to the species and colligate with sensations similarly of intense affective quality: for instance, those concerned with sexual functions. In the male frog the sexual clasp is a spinal reflex. The cord may be divided both in front and behind the brachial region without interrupting the reflex. Experiment shows that from the spinal male at the breeding season, and also at other times, this reflex is elicited by any object that stimulates the skin of the sternal and adjacent region. In the intact animal, on the contrary, other objects than the female are, when applied to that region, at once rejected, even though they be wrapped in the fresh skin of the female frog and in other ways made to resemble the female. The development of the reflex is not prevented by removal of the testes, but removal of the seminal reservoirs is said to depress it, and their distension, even by indifferent fluids, to exalt it. If the skin of the sternal region and arms is removed the reflex does not occur. Severe mutilation of the limbs and internal organs does not inhibit the reflex, neither does stimulation of the sciatic nerve central to its section. The reflex is, however, depressed or extinguished by strong chemical and pathic stimuli to the sternal skin, at least in many cases. The tortoise exhibits a similar sexual reflex of great spinal potency.

It would seem a general rule that reflexes arising in species of receptors which considered as sense-organs provoke strongly affective sensation caeteris paribus prevail over reflexes of other species when in competition with them for the use of the "final common bath."

Of all reflexes it is those of ordinary posture that are the most casily interrupted by other reflexes. Even a weak stimulation of the noci-ceptive arcs arising in the foot often suffices to lower or abolish the knee-jerk or the reflex extensor tonus of the elbow or knee. If various species of reflex are arranged, therefore, in their order of potency in regard to power to interrupt one another, the reflexes initiated in receptors which considered as sense-organs excite sensations of strong affective quality lie at the upper end of the scale, and the reflexes that are answerable for the postural tonus of skeletal muscles lie at the lower end of the scale. One great function of the tonic reflexes is to maintain habitual attitudes and postures. They form, therefore, a nervous background of active equilibrium. It is of obvious advantage that this equilibrium should be easily upset, so that the animal may respond agilely to the passing events that break upon it as intercurrent stimuli.

Results.—Intensity of stimulation, fatigue and freshness, spinal induction, functional species of reflex, are all, therefore, physiological factors influencing the result of the interaction of reflexarcs at a common path. It is noticeable that they all resolve them-

selves ultimately into intensity of reaction. Thus, intensity of reflex which are habitually prepotent in interaction with others are those which are habitually prepotent in interaction with others are those which are habitually intense; those specially impotent in competition are those habitually feeble in intensity, e.g., skeletal muscular tone. The tonic reflexes of attitude are of habitually low intensity, easily interfered with and temporarily suppressed by intercurrent reflexes, these latter having higher intensity.

The high variability of reflex reactions from experiment to experiment, and from observation to observation, is admittedly one of the difficulties that has retarded knowledge of them. Their variability, though often attributed to general conditions of nutrition, or to local blood-supply, etc., seems far more often due to changes produced in the central nervous organ by its own functional conductive activity apart from fatigue. This functional activity itself causes from moment to moment the temporary opening of some connections and the closure of others. The chains of neurones, the conductive lines, have been, especially in recent years, by the methods of Golgi, Ehrlich, Apathy, Cajal and others, richly revealed to the microscope. Anatomical tracing of these may be likened, though more difficult to accomplish, to tracing the distribution of blood vessels after Harvey's discovery had given them meaning, but before the vasomotor mechanism was discovered. The blood vessels of an organ may be turgid at one time, constricted almost to obliteration at another. With the conductive network of the nervous system the temporal variations are even greater, for they extend to absolute withdrawal of nervous influence. Under reflex inhibition a skeletal muscle is relaxed to its post-mortem length, i.e., there may then be no longer evidence of even a tonic influence on it by its motor neurone. The final common path is handed from some group of a plus class of afferent arcs to some group of a minus class, or of a rhythmic class, and then back to one of the previous groups again, and so on. The conductive web changes its functional pattern with certain limits to and fro. It changes its pattern at the entrances to common paths. The changes in its pattern occur there in virtue of interaction between rival reflexes: occlusion, substitution by equivalence, inhibition, immediate induction, successive induction, fatigue, are factors. As a tap to a kaleidoscope, so a new stimulus that strikes the receptive surfaces causes in the central organ a shift of functional pattern of the linkage. The central organ is a vast network whose lines of conduction follow a certain scheme of pattern, but within that pattern the details of connection are, at the entrance to each common path, mutable. The grey matter may be compared with a telephone exchange, where, from moment to moment, though the end-points of the system are fixed, the connections between starting-points and terminal points are changed to suit passing requirements, as the functional points are shifted at a great railway junction. In order to realize the exchange at work, one must add to its purely spatial plan the temporal datum that within certain limits the connections of the lines shift to and fro from minute to minute. An example is the "reciprocal innervation" of antagonistic muscles-when one muscle of the antagonistic couple is thrown into action the other is thrown out of action. This is only a widely spread case of the general rule that antagonistic reflexes interfere where they embouch upon the same final common paths. And that general rule is part of the general principle of the mutual interaction of reflexes that impinge upon the same common path. Unlike reflexes have successive but not simultaneous use of the common path; like reflexes mutually reinforce each other on their common path. Expressed teleologically, the common path, although economically subservient for many and various purposes, is adapted to serve but one purpose at a time. Hence it is a co-ordinating mechanism and prevents confusion by restricting the use of the organ, its minister, to but one action at a

In the case of simple antagonistic muscles, and in the instances of simple spinal reflexes, the shifts of conductive pattern due to interaction at the mouths of common paths are of but small extent. The co-ordination covers, for instance, one limb or a pair of limbs. But the same principle extended to the reaction of the great arcs arising in the projicient receptor organs of the head,

 $e\,g$ , the eye, which deal with wide tracts of musculature  $as\,a$  whole, operates with more multiplex shift and wider ambit. Releasing forces acting on the brain from moment to moment shut out from activity whole regions of the nervous system, as they conversely call vast other regions into play. The resultant singleness of action from moment to moment is a keystone in the construction of the individual whose unity it is the specific office of the nervous system to perfect. The interference of unlike reflexes and the alliance of like reflexes in their action upon their common paths seem to lie at the very root of the great psychical process of "attention."

The spinal cord is not only the seat of reflexes whose "centres" lie wholly within the cord itself; it supplies also conducting paths for nervous reactions initiated by impulses derived from afferent spinal nerve, but involving mechanisms situate altogether headward of the cord in the brain. Many of these reactions affect consciousness, occasioning sensations of various kinds.

Besides the paths followed by headward-running impulses the spinal cord contains paths for impulses passing along it backward from the brain. These paths lie almost entirely in the ventrolateral columns of the cord. The fibres of which they are composed cross but little in the cord. Their sources are various, some come from the hind brain and some from the mid-brain, and in the higher mammalia, especially in man and in the anthropoid apes, a large tract of fibres in the lateral column (the crossed pyramidal tract) comes from the cortex of the neopallium of the fore brain. This last tract is the main medium by which impulses initiated by electrical stimulation of the motor cortex reach the motoneurones of the cord and through them influence the activity of the skeletal muscles.

Of the function of the other tracts descending from the brain into the cord little is known except that mediately or immediately they excite or inhibit the spinal motoneurones by various levels. How they harmonize one with another in their action or what their purpose in normal life may be is at present little more than conjecture.

Such terms, therefore, as "paths for volition," etc., are at present too schematic in their basis to warrant their discussion here.

SPINDLE TREE (Evonymus europaeus), so-called from its tough wood being formerly used for spindles, a small tree of the family Celastraceae, native to Europe and sparingly naturalized in eastern North America. The wood furnishes good charcoal. (See EVONYMUS; WAHOO.)

SPINEL, in mineralogy, the name given to a group of minerals, of the general composition R"O.R<sub>2</sub>"O<sub>3</sub>, Where R"=Mg, Fe, Mn, Zn, and R"=Al, Fe", Cr". The typical member is MgO.Al<sub>2</sub>O<sub>3</sub>, a magnesium aluminate to which the name (Fr. spinelle, from the Latin "spina," perhaps in allusion to the sharp angles of the crystals) was originally restricted. All spinels crystallize in the cubic system, typically in octahedra. Twinning is common, the octahedral face being the twin plane, giving a characteristic form known as the spinel twin.

The group of spinel minerals includes the following members: Magnesioferrite MoFe.O. MgAl<sub>2</sub>O<sub>4</sub> Magnesia spinel . FeFe<sub>2</sub>O<sub>4</sub> . (Mg,Fe) Al<sub>2</sub>O<sub>4</sub> Magnetite Gahnite . ZnAl<sub>2</sub>O<sub>4</sub> Hercynite .FeAl<sub>2</sub>O<sub>1</sub> Franklinite (Zn,Mn) Fe2O4 . (Mg,Fe) (Al,Cr)2O4 Picotite Chromite FeCr.O.

Cleavage is typically absent in these minerals with the exception of the zinc spinel (cleavage on 111), but an octahedral parting is observable in magnetite and franklinite. The hardness is variable, in ordinary spinel 7.5–8, but magnetite H=6 and chromite H=5.5. The specific gravity varies with the composition, from 3.6 (magnesia-spinel) to 5.2 (magnetite). The light refraction shows a range from 1.718 (pure MgAlaO4), hercynite 1.80, to picotite 2.05, chromite 2.10 and magnetite 2 42.

Spinels vary much in colour. Magnesia spinels are pink, red and blue, and are used as gem stones. The pure magnesia spinel is colourless, hercynite is dark green in thin slices and picotite and chromite are brown in the thinnest sections. Spinels are readily produced artificially. Magnesia spinel melts at 2135° C. and between this compound and FeAl<sub>2</sub>O<sub>4</sub> there is complete miscibility as revealed in spinel analyses, but solid solution between (Mg, Fe) Al<sub>2</sub>O<sub>4</sub> and magnetite is very limited. The spinels used in jewellery are found mostly in gem gravels, the chief localities being Ceylon, Thailand and Upper Burma.

Spinels occur both in igneous and metamorphic rocks. The home of the magnesia spinel is in thermally altered dolomites where it arises by reaction of alumina with dolomite. There it is usually accompanied by calcite and forsterite. The iron-rich member, pleonaste, is common both in ultrabasic rocks such as dunites and in quartzless argillaceous hornfelses and gneisses. In these latter it is almost universally accompanied by cordierite and frequently by sillimanite, andalusite or corundum. Hercynite is characteristic of the granulites of Saxony in association with garnet, sillimanite, etc.

The chromiferous spinel, picotite, is relegated to the ultrabasic rocks, as dunite, therzolite and the serpentines derived from them Gahnite, the zinc spinel, occurs in schists associated with zinc ores, and in pegmatites in Finland and at Broken Hill, N.S.W., while franklinite is associated with zinc and manganese minerals in limestone at Franklin Furnace, N.J. (See also Chromite; Macnetics) (C. E. T.)

SPINELLO, ARETINO (c. 1330-1410), Italian painter, the son of a Florentine named Luca, who had taken refuge in Arezzo in 1310 when exiled with the rest of the Ghibelline party, was born at Arezzo about 1330. Spinello was a pupil of Jacopo di Casentino, a follower of Giotto, and his own style was a sort of link between the school of Giotto and that of Siena. In the early part of his life he worked in Florence painting frescoes, nearly all in terra verde in the churches, the Carmine, Sta. Maria Novella and elsewhere. These works are no longer extant. Between 1360 and 1384 he was occupied in painting many frescoes in and near Arezzo, almost all of which have perished. After the sack of Arezzo in 1384 Spinello returned to Florence, and in 1387-1388 with some assistants covered the walls and vault of the sacristy of S. Miniato near Florence with a series of frescoes, the chief of which represent scenes from the life of St. Benedict. Of his later works the chief are the very fine series of frescoes painted in 1407-1408 in the Salia di Balia in the Palazzo Pubblico at Siena; these are the finest of Spinello's existing frescoes. Spinello died at Arezzo on March 14, 1410.

See Sir Dominic Colnaghi, Dictionary of Florentine Painters (1928).

SPINET or SPINNET, names given in England to all small keyboard instruments irrespective of shape, having one string to a note, plucked by means of a quill or plectrum of leather. The earliest name recorded for this instrument is clavicymbalum, which occurs in the rules of the Minnesingers (1404). In the 20th century the term "spinet" was adopted in the U.S. to describe a small upright piano. (See HARPISCHOED.)

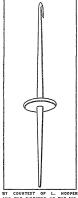

**SPINNING**, the forming of threads by drawing out and twisting various fibres. There is ample evidence of the great antiquity and wide diffusion of the art of spinning, for spinning necessarily precedes weaving (q.v.) whenever short fibrous materials

have to be made into threads, and weaving is one of the primal and most universal employments of mankind. No art which has been so long and widely practised remained so unprogressive as that of spinning. On the other hand, since about the middle of the 18th century, when human ingenuity bent itself in earnest to improve the art, there have not been developed in the whole range of mechanical industries machines of greater variety,

delicacy of action and capacity than those

now in use for spinning.

The primitive thread-making implement consisted of a wooden spindle, from 9 to 15in. long, which was rounded and tapered at both extremities, as in the accompanying figure. Near the top there was usually a notch in which the yarn was caught while undergoing the operation of twisting, and lower down a whorl, or wharve, composed of a perforated disk of clay, stone, wood, or other material was secured to give momentum and steadiness to a rotating spindle. Long fibres were commonly attached to a distaff of wood, which was held under the left arm of the operator, but short fibres were spun from carded rolls. After attaching some twisted fibres to the spindle, a rotatory motion was given to the latter either by rolling it by hand against one thigh, or by twirling it between the fingers and thumb of the right hand, after which the fibres were drawn out in a uniform strand by both hands and converted into BY COUNTEST OF L. HOOPER yarn. When the thread was of sufficient TORIA AND ALBERT MUSEUM strength, the spindle was suspended by it until a full stretch had been drawn and until a full stretch had been drawn and twisted, after which that portion was wood and was from 9in. to wound upon the body of the spindle, and 15in. long

AN EARLY SPINDLE

the operation continued until the spindle was filled. The quantity thus rolled up gives the name to a now definite measure of linen yarn, namely "the spindle," or 14,400 yards. Simple as was this primitive apparatus, a dexterous spinner could produce yarn of an evenness, strength and delicacy such as has scarcely been exceeded by elaborate modern appliances. The yarns for the gossamer-like Dacca muslins of India were so fine that r lb. weight of cotton was spun into a thread nearly 253m. long. This was accomplished with the aid of a bamboo spindle not much bigger than a darning needle, and which was lightly weighted with a pellet of clay. Since such a tender thread could not support even the weight of so slight a spindle, the apparatus was rotated upon a piece of hollow shell. The spindle as here described was, so far as is known, the sole apparatus with which yarn was spun until comparatively recent times.

Modern Spinning .- Modern changes have had for their obiect: (1) the providing of mechanical means to rotate the spindle, (2) an automatic method of drawing out the fibres, and (3) devices for working a large group of spindles together, at rapid speeds.

The first improvement consisted in cutting a ring groove in the wharve, mounting the spindle horizontally in a frame, and passing a band from a large wheel round the wharve. A rotatory motion was then given to the spindle by turning the wheel with the left hand. After attaching the filaments to the spindle they were attenuated with the right hand, and when fully twisted the thread was moved to form a right angle with the spindle and coiled upon it. Such a wheel has long been known in India, and from a drawing in a 14th-century manuscript in the British Museum it is obvious that it was not unknown, although far from being in general use, in Europe at that early date. It came ultimately to be known in England as the "bobbing wheel," and was in constant use down to the beginning of the 19th century for spinning coarse and fine yarns. But fine yarns received two spinnings; the first consisted in drawing out and slightly twisting the fibres into what is still known as a roving, and by the second spinning the roving was

fully attenuated and twisted In 1533, a citizen of Brunswick is said to have cranked the axis of the large wheel and added a treadle, by which the spinner was enabled to rotate her spindle with one foot and have both hands free to manipulate the fibres.

It is not possible accurately to fix the dates at which all improvements in spinning appliances were made; it is certain that many were known and used long before they were generally adopted Thus the flyer, which twists yarn before winding it upon a bobbin, is shown in a drawing by Leonardo da Vinci, together with a device for moving the bobbin up and down the spindle so as to effect an even distribution of the yarn. During the 16th century a machine of the foregoing type was widely used, and came to be known as the Saxony wheel. It changed spinning from an intermittent to a continuous operation The spindle had affixed upon its outer end a wooden flyer, whose forked legs were far enough apart to enclose a double-flanged spool, and at short intervals bent wires, known as the heck, were inserted in each leg for the purpose of guiding the thread evenly upon the spool. This spool was loosely threaded upon the spindle and one of its flanges was grooved to take a driving band from the large wheel, hence the spindle and the spool were separately driven, but the former at a higher speed than the latter. The twisted filaments were drawn through an eye in the flyer, led along one of its legs, and made fast to the spool. By operating the treadle the flyer twisted all the fibres about a common axis once for each revolution, and the spool wound up the length thus spun: the thread being slipped from tooth to tooth of the heck at regular intervals to direct it evenly across the spool.

The remaining part of the problem which lay before inventors was to draw out masses of parallel fibrous material, and twist them into uniform strands by mechanical means. The first stage in the evolution of mechanical spinning was effected by the invention of Lewis Paul, of Birmingham, who obtained a patent in 1738, and who was assisted by John Wyatt. The essential features of this invention consisted in passing carded slivers between pairs of parallel rollers, each succeeding pair of which moved faster than the preceding pair, to attenuate the sliver to the required extent. From Paul's specification it would appear that he attempted to turn the rollers about their horizontal and vertical axes simultaneously, in order to draw out the fibres and twist them at one operation. But he also mentions a plan for which he procured a patent 20 years later, namely, the use of only one pair of rollers working in conjunction with a bobbin which drew off the thread faster than the rollers delivered the sliver, and coiled the thread about itself. The bobbin, therefore, attenuated, twisted and wound the material. Neither plan proved a commercial success. Thomas Highs, of Leigh, and others, laboured upon the problem, but it was left to Richard Arkwright, a barber, of Preston and Bolton, to achieve what his predecessors vainly struggled for. He obtained patents, in 1769 and 1775, for a machine which was subsequently known as the water-twist frame by reason of water-power being applied to drive it. Arkwright's first machine did not contain any really new feature, for it consisted of Paul's drawing rollers, and the spindle, fiver and spool from the Saxony wheel, but the spindles and rollers were grouped in sets of four. Later the water-twist frame was changed into the "throstle" frame, which in turn has almost ceased to be used. In 1829 C. Danforth (1797-1876), an American spinner, invented a dead spindle, on the top of which he placed a hollow cap to serve as the winding point, and inside the cap he rotated a spool: a plan still used by worsted spinners. In 1828 Mr. Thorpe, also an American, invented the ring spinning frame, whose principal feature consisted in the substitution for the flyer of a flanged annular ring, and a light C-shaped traveller. By means of the traveller a thread was held in the best position for winding upon a spool, as well as put under the necessary tension. Later inventors have so altered the construction of the ring, traveller and spindle that a speed of upwards of 11,000 revolutions per minute can now be attained. This represents the highest development of continuous

Whilst endeavours were being made to perfect continuous spinning, attention was also directed to perfecting the intermittent

process as represented by the bobbing wheel. Between the years 1764 and 1767, James Hargreaves, of Standhill, invented the spinning jenny, by the aid of which 16, or more, threads could be spun simultaneously by one person. All the spindles were placed vertically and rotated from a drum, but the rovings were mounted in a movable carriage and passed between a clamp that opened and shut like a parallel ruler. After securely clamping the rovings and attaching them to the spindles, the carriage was drawn out slowly by one hand and the spindles revolved by the other. The rovings were thus stretched to the proper degree of tenuity, and sufficiently twisted. This was followed by the inward run of the carriage, when the stretch of spun threads was wound upon the spindles, and the operation repeated Hargreaves therefore returned to the first principles of spinning, viz., simultaneous drawing and twisting. But although the jenny gave a greatly increased output, it was ill adapted for fine spinning. During the years 1774 to 1779, Samuel Crompton, of Bolton, combined, in the mule, the drawing rollers of Paul with the stretching of Hargreaves. But his rollers did not fully attenuate the rovings before twisting them, as is the case with continuous spinning, neither was stretching alone relied upon. From its introduction this machine was able to spin finer and more elastic threads than any of its rivals, but for a time the preparation of suitable rovings was a source of great trouble. The immediate consequence of the decision of the court of king's bench, in 1785, to throw open to the public Arkwright's preparatory machinery, was an enormous increase in the usefulness of the mule. Since Crompton's time a host of inventors have laboured to render all parts of the mule thoroughly automatic; this has led to many changes and additions, but none of its essential features has been discarded. The inventions of Paul, Arkwright, Hargreaves and Crompton are at the foundation of all modern systems of spinning; for details regarding them see Cotton and the Cotton Industry. Cotton-Spinning and Manufacture. (T. W. F.)

SPINOLA, AMBROSE, Marquis de los Balbases (1569-1630), Spanish general, born in Genoa, then practically a protected state under the power of Spain. The family of Spinola was of great antiquity, wealth, and power, and a rival of the house of Doria for authority within the republic. Unsuccessful in a lawsuit against the Dorias, Spinola decided to advance the fortunes of his house by serving the Spanish monarchy in Flanders. In 1602, he and his brother Frederick entered into a contract with the Spanish government. It was a speculation in which Spinola risked the whole great fortune of his house. Frederick. who was to form a squadron of galleys for service on the coast, was killed in action with the Dutch (May 24, 1603). Spinola's first landing in Flanders resulted in nothing definite and he returned at the end of 1602 for more men. On Sept. 29, 1603, he laid siege to Ostend and took it on Sept. 22, 1604, winning thereby a high reputation among the soldiers of his time. A visit to the Spanish court at Valladolid, resulted in his being appointed commander-in-chief in Flanders. The wars of the Low Countries consisted at that time almost wholly of sieges, and Spinola made himself famous by the number of places he took in spite of the efforts of Maurice of Nassau to save them.

On the outbreak of the Thirty Years' War Spinola conducted a vigorous campaign in the lower Palatinate, and was rewarded by the grade of captain-general. The most renowned victory of his career-the capture of Breda after a long siege (Aug. 28, 1624-June 5, 1625)—is the subject of the great picture by Velazquez, known as "Las Lanzas"; the portrait of Spinola is from memory. The taking of Breda was the culmination of Spinola's career. The enmity of Olivares and the want of money paralysed his efforts. Appointed plenipotentiary and general in the war over the succession to the Duchy of Mantua, Spinola landed at Genoa on Sept. 19, 1629. In Italy, Olivares caused him to be deprived of his powers as plenipotentiary, and, broken down in health, he died on Sept. 25, 1630, at the siege of Casale.

n health, he died on Sept. 25, 205, h. See A. Rodríguez Villa, Ambrosio Spinola . . . (Madrid, 1905).
(D. H.)

forms: Espinoza, d'Espinoza, Despinoza, de Spinoza, and simply Spinoza. His first name was Baruch (Hebrew for "Blessed"); but, in accordance with the custom of the time, it was rendered into its Latin equivalent (Benedictus).

## THE LIFE AND WRITINGS OF SPINOZA

Early Years (1632-1654).-Spinoza was born in Amsterdam on November 24, 1632. The house in which he first saw the light, and in which he passed his early years, occupied the site of what is now No 41, Waterlooplein. His grandfather (Abraham) and his father (Michael) were Portuguese crypto-Jews, that is, descendants of Jews whom the Inquisition had compelled to embrace Christianity but who remained Jews at heart. When the Netherlands revolted against Spain and the Spanish Inquisition, in 1567, and the Union of Utrecht decreed, in 1579, that "every citizen shall remain free in his religion," many crypto-Jews in Spain and Portugal turned their eyes to Holland in the hope of finding refuge there from their common oppressors. The destruction of the Spanish Armada, in 1588, probably favoured schemes of escape. So in 1593 the first batch of Jewish refugees arrived in Amsterdam. Among these early arrivals were Spinoza's father and grandfather They hailed from Vidigueira, near Beja, in the South of Portugal, but appear to have stayed for a while in Nantes (France) before settling in Amsterdam. Spinoza's mother came from Lisbon. She died in 1638, when Spinoza was barely six years old.

The Spinozas were fairly well-to-do merchants. Spinoza's grandfather was regarded as the head of the Amsterdam Jewish community from about 1628 onwards, and Spinoza's father was Warden of his synagogue on many occasions, also Warden of the Jewish School, and President of a Jewish Charity which granted loans free of interest. Under the circumstances it may be assumed that Spinoza attended the school for Jewish boys, founded about 1638. The curriculum of this school is well known, so we have a sufficiently clear idea of Spinoza's early education The school hours were 8 till 11 A.M. and 2 till 5 P.M. The subjects were all Hebrew—the Old Testament, the Talmud, Hebrew Codes, and the works of Ibn Ezra, Maimonides, Crescas and others. Outside school hours the boys had private lessons in secular subjects. The vernacular used in the Jewish school and in Jewish homes was Spanish. Spinoza learned Latin from a German scholar, Jeremiah Felbinger, who may also have taught him German. Spanish and Portuguese Spinoza learned from his father, Dutch from his environment, and he also knew some French and Italian. When exactly he learned mathematics and physics is not known. There were plenty of Hebrew books dealing with these sciences, and the Jewish School had a good lending library, so that Spinoza may have commenced these studies during his school years. Hence probably his choice of the profession of a maker of lenses.

Of Spinoza's teachers at the Jewish School the most eminent were Saul Morteira and Manasseh ben Israel. Morteira was born in Venice in 1596, and studied medicine under Montalto, the crypto-Jewish Court physician of Maria de Medici. He came to Amsterdam in 1616, and in 1638 was elected presiding Rabbi of the Amsterdam synagogues. Manasseh ben Israel was born in Lisbon in 1604. His father was one of 150 Jews whom the Inquisition condemned to the flames in 1605. They managed to save their lives at the expense of their fortunes, and fled at the earliest opportunity. Manasseh's parents brought him to Amsterdam about 1606. In 1622 he became the youthful Rabbi of one of the Amsterdam synagogues (the "Habitation of Peace"). In 1627 he started a Hebrew printing press, and in 1640 he was appointed to one of the senior posts in the Jewish School.

In March 1654 Spinoza's father died. There was some litigation over the estate, as Spinoza's only surviving step-sister claimed it all. Spinoza won the lawsuit, but allowed her to retain nearly everything. Henceforth Spinoza had to fend for himself.

Critical Years (1654-1656).-Spinoza was in his twentysecond year when his father died. His studies so far had been mainly Jewish. But he was an independent thinker and he had SPINOZA, BENEDICTUS DE (1632-1677), Dutch philosopher and maker of lenses. The surname occurs in various orthodox theology. In the Biblical commentary by Abraham Ibn

Ezra (1092-1167) one meets with many "a word to the wise" directing attention to some inconsistency in Scripture, to the post-Mosaic authorship of parts at least of the so-called "Five Books of Moses," or to the different authorship of the two parts of Isaiah. In the Guide of the Perplexed of Moses Maimonides (1135-1204) attention is drawn to various crudities in Biblical theology, and to the provisional character of certain Biblical ordinances. In the writings of Gersonides (1288-1344) rationalism encroaches on miracles and prophecy in an attempt to eliminate the element of supernaturalism. Already Maimonides had insisted on interpreting Scripture in such a way as to harmonize it with reason. Gersonides went further than that. He faced the possibility of a conflict between Reason and Revelation, and maintained that, in such an event, the Bible "cannot prevent us from holding that to be true which our reason prompts us to believe." Again, the popular conception of the world's creation out of nothing was denied by both Ibn Ezra and Gersonides, who believed in the eternity of matter. Maimonides also repudiated the belief that man is the centre of creation, maintaining that each thing exists for its own, not for man's, sake; he also suggested the relativity of good and evil. The Jewish Mystics had taught that Nature is animated. Crescas (1340-1410) ascribed extension to God, denied the validity of the conception of final causes (or the explanation of objects and events by reference to their alleged purposes), and, like Ibn Ezra, maintained a thoroughgoing determinism. Here was food enough for thought. and incentive enough for heresy.

Moreover, the tendency to revolt against mere tradition and authority was very much in the air since the Renaissance, and it affected young Jews as others. There was the tragic figure of Gabriel da Costa, or Uriel Acosta (1585-1640). A crypto-Tewish refugee from Oporto, in Portugal, he settled in Amsterdam. He was opposed to the belief in immortality, and to various Jewish rites, on the ground that they were not Biblical. He was excommunicated by the Jewish authorities, recanted, then returned to the charge, was excommunicated again, recanted again under humiliating conditions, and shot himself. In his naturalistic outlook he was a forerunner of Spinoza. Especially interesting for the understanding of Spinoza is the case of another Jewish doctor of Amsterdam-Daniel de Prado (d. 1663). He too was opposed to supernaturalism and traditionalism, and appears to have influenced young people to adopt similar views. He was persuaded to recant in the synagogue in 1656, but there was no material change in his attitude. The synagogue authorities tried to bribe him to go abroad, but he declined, and was excommunicated in 1657. A contemporary poet, punster and protector of the faith (Isaac Orobio de Castro) wrote an invective in verse against de Prado as a philosophaster who led astray young students. Tewish and non-Tewish. Some of the allusions in this invective most probably refer to Spinoza, the record of whose excommunication faces the page in the communal minute book on which de Prado's recantation is recorded. Some of the writings of Jewish authors of the period (Samuel da Silva, Manasseh ben Israel, Orobio de Castro, etc.) in defence of immortality, revelation and tradition afford considerable evidence of the intellectual ferment in Amsterdam Jewry. And the religious leaders of the day were not particularly tactful or tolerant. They were alarmed by heresies which were at least as anti-Christian as anti-Jewish, and were afraid of giving offence in a country of which they were not yet regarded as citizens. This alarm shows itself in the attempt to bribe de Prado and Spinoza into silence. But they were also imbued with something of the intolerant spirit of the Inquisition, whose victims they had been. In 1640, they actually put the ban on Manasseh ben Israel for some trivial reason, though they rescinded it soon afterwards.

The views which brought Spinoza into collision with the synagogue authorities were essentially the same as those of Farrar, Acosta and de Prado. In conversation with other students he told them that there is nothing in the Bible to support the views that God has no body, that there really are angels (as distinguished from merely imaginative visions of them), and that the soul is immortal. He also expressed his belief that the author

of the Pentateuch was no wiser in matters pertaining to physics or even theology than they were. These utterances were reported to the Jewish authorities, who after vainly trying to silence him with bribes and threats excommunicated him in July 1656. The fact of his excommunication was formally reported to the civil authorities—a gesture intended to absolve the Jewish community from all responsibility for Spinoza's heresies. And Spinoza was banished from Amsterdam for a short period.

There is no evidence that Spinoza really wanted to break away from the Tewish community. Such evidence as there is rather points the other way. On December 5, 1655, he attended service in the synagogue and made an offering. In view of his impecuniosity, offerings must have been rare events for him, and it may be assumed that he also went to the synagogue after that date, certainly in March 1656, the anniversary of his father's death. Shortly before or after his excommunication he also addressed an Apology (or defence of his views) to the synagogue authorities. Apparently he was not entirely indifferent to their opinions of him. Possibly if Manasseh ben Israel had not been away in London at the critical time, the whole storm would have blown over. As it was, tactlessness, mischief making, alarm and intolerance were in the saddle and rode for a fall. In his 24th year Spinoza stood alone, but unafraid, and uplifted by his destiny to become one of the great lights of humanity.

Years of Re-Orientation (1656-1660).-Already before his estrangement from the synagogue Spinoza had become acquainted with a number of Christians. Among these was a certain Francis van den Enden, an ex-Jesuit and ex-bookseller, but an ardent classical scholar and something of a poet and dramatist, who opened a school in Amsterdam in 1652. For a time Spinoza stayed with Van den Enden, assisting with the teaching of the school children, and receiving help in his own further education. In this way Spinoza improved his knowledge of Latin, learned some Greek, was introduced to the Neo-Scholastic philosophy of such writers as Burgersdijck (d. 1632) and Heereboord (d. 1659), and possibly also to the works of Descartes. In any case Spinoza's other Christian acquaintances were mostly Collegiants who were especially interested in the "new philosophy" of Descartes. At the same time he was learning the science and art of making lenses, in which he became a great expert. After his excommunication Spinoza spent some weeks, or possibly months, at Ouwerkerk, a village south of Amsterdam, and then returned to his native city, where he stayed until 1660. He supported himself partly by grinding and polishing lenses for spectacles, telescopes and microscopes, and partly by helping various people with their private studies. Holland was a country of many religious sects whose friction with the predominant Calvinist clergy imparted considerable vitality to theological problems and connected philosophical questions. As all these reformation movements were, or professed to be, "back to the Bible," a knowledge of Hebrew was felt to be necessary, and Hebrew experts like Spinoza were in some demand. The same was true of philosophy as an aid to theology. Accordingly, a number of amateur theologians secured the services of Spinoza to help them with their studies, and through them he also came into contact with others. Of his friends and acquaintances during this period the most important were Pieter Balling, Jarig Jelles, Lodewijk Meyer, Simon Joosten de Vries, and Jan Rieuwertsz. The sincerity of Simon Joosten de Vries's admiration for Spinoza was shown in many ways. At one time he pressed Spinoza to accept a gift of 2,000 florins, at another time he wanted to make Spinoza his sole heir, but in vain. By his will he left Spinoza an annuity of 500 florins, but Spinoza would not accept more than 300. Some or all of these and certain others formed a kind of reading and discussion circle for the study of religious and philosophical problems under the guidance of Spinoza. At first, we may assume, Cartesian philosophy played an important part in these discussions. For at that time there was something like a coalition between the "new philosophy" and liberal, dissenting theology, for they were both opposed by the dominant Calvinists. Most of his Collegiant friends remained Cartesian to the end, though Spinoza himself never followed Descartes in anything

except his science.

To judge from the opening passage of his Treatise on the Improvement of the Understanding, which was written shortly afterwards, the years 1656 to 1660 must have been years of storm and stress in Spinoza's mental history. Cut off from kith and kin. and left stranded as the result of his honest attempt to think independently, worldly aims must have seemed at times more alluring than the beck of the spirit. But his higher self won through, partly perhaps with the help of the faith which his unsophisticated friends and disciples placed in knowledge and in him. His new orientation was accomplished by the end of this period. He had learned to view life and its problems from other angles than those of his native environment, and he had acquired a knowledge of a language and a system of concepts more suitable to serve as a vehicle for the great thoughts that were taking shape in his mind, and more suitable, too, for the wider influence which they were destined to exercise. What he needed now was peace and quiet in which to collect his thoughts and reduce them to system. He withdrew accordingly to Rijnsburg, a quiet unworldly village on the old Rhine, about six miles from Leyden.

Life at Rijnsburg (1660-1670).—Rijnsburg was the headquarters of the Collegiants. Arrangements for his stay there were no doubt made by his Collegiant friends. He lodged with a surgeon named Hermann Homan, whose humanitarianism is obvious from the inscription on the cottage wall:

Alas! if all men were but wise, And would be good as well, The Earth would be a Paradise, Where now 'tis mostly Hell.

(From Kamphuysen's May Morning). In this cottage (now Het Spinozahuis) Spinoza wrote his Short Treatise on God, Man and his Well-being, the Treatise on the Improvement of the Understanding, the greater part of his Geometric Version of Descartes' Principia with the appendix on Metaphysical Thoughts. and the first book of his Ethics. Part of the Short Treatise consists of notes which he had prepared in connection with the study circle in Amsterdam. This circle continued to meet after Spinoza's departure from Amsterdam, and periodically Spinoza sent them the various parts of his Short Treatise and other works for study and discussion. This is clear from Letters VIII. and IX. (The Correspondence of Spinoza, pp. 101 seq.) and from the closing sentences of the Short Treatise (pp. 149 seg. in A. Wolf's edition). The Short Treatise and the Treatise on the Improvement of the Understanding were ready in or before April 1662, and were originally intended to be one work, as is clear from Spinoza's third letter to Oldenburg (Correspondence, pp. 98 seq.). Already in these earlier writings Spinoza's attitude is anti-Cartesian.

During his stay in Rijnsburg Spinoza met various interesting people. Especially noteworthy are Steno, the founder of modern geology, and Oldenburg, one of the first two secretaries of the Royal Society of London, Steno subsequently turned Roman Catholic and tried to persuade Spinoza to do likewise (see Correspondence, pp. 324 seq.); but he has the merit of having recognized in Spinoza "the reformer of the new philosophy." Oldenburg is of special interest in a biography of Spinoza because the most important part of Spinoza's correspondence passed between him and Oldenburg. Oldenburg visited Leyden in 1661. His countryman Coccejus was professor there. Spinoza must have acquired a reputation somehow, for Oldenburg went out of his way to visit him in Rijnsburg. The deep impression which Spinoza made on Oldenburg (who was about 18 years older than Spinoza) is evident from his first letter to Spinoza (see Correspondence, pp. 73 seq.). In Rijnsburg also Spinoza first met the brothers Koerbagh whose subsequent tragic fate showed how little freedom of thought there really was even in Holland. Casearius, another student at the University of Leyden, came to spend a year or so in Rijnsburg, and stayed in the same cottage as Spinoza, who instructed him in the philosophy of Descartes. For this purpose Spinoza made a geometrical version of the second part of Descartes' Principia. While on a visit to Amsterdam, in 1663, Spinoza showed this to his Cartesian friends, who

persuaded him to do the same with the first part of the Principia. He did so in a fortnight. These two parts, together with an appendix called Metaphysical Thoughts, were accordingly published by his friends in 1663. L. Meyer wrote the introduction explaining that Spinoza did not really share the views expressed in the book; J. Rieuwertsz was the publisher; and J. Jelles defrayed the cost. This was the only book published in Spinoza's life-time with his name on the title-page. P. Balling prepared a Dutch translation of this book, and published it in 1664.

Early in 1662 Spinoza had completed the first draft of his philosophy in one work combining the Short Treatise and the Treatise on the Improvement of the Understanding. He was not satisfied with its style or with its method of exposition. He had tried the dialogue form without success, so he tried the geometrical method, in the manner of Euclid's Elements, which gave him more satisfaction. He therefore decided to lay aside his earlier attempts and make a new start. Thus originated his Ethics. the first book of which was finished, and in the hands of his friends, early in 1663. The title of the whole work was not yet intended to be Ethics, but "On God, the Rational Soul, and the Highest Happiness of Man," and the work was planned in three parts corresponding to the three parts of the title, instead of the five parts into which it eventually developed. The publication of his version of Descartes' Principia was intended to prepare the way for the publication of his own philosophy. For this purpose two things were necessary. He had to secure the patronage of influential men who could shield him and his book from the remorseless hostility of the Calvinist clergy and other fanatics, and he had to show to the more philosophically minded people, who were mostly Cartesians, that his rejection of Cartesianism was not due to ignorance (see Correspondence, pp. 123 seq., and The Oldest Biography of Spinoza, pp. 57 seq., 147 seq.). Spinoza appears to have succeeded so far as to win the interest of a few people belonging to the governing class. These afforded him some protection, but not sufficient to enable him to publish his philosophy in his life-time. Among these were J. Hudde (who subsequently became Sheriff and then Burgomaster of Amsterdam, and a member of the States of Holland), H. Boxel (Pensionary of Gorkum), C. Burgh (who became Treasurer General of the United Netherlands in 1666), possibly also C. van Beuningen (at one time Burgomaster of Amsterdam) and Jan de Witt (Grand Pensionary of Holland).

In June 1663 Spinoza moved from Rijnsburg to Voorburg, near The Hague. Here Spinoza got to know Vossius the philologist, who was subsequently appointed Canon of Windsor, and Christiaan Huygens, the discoverer of Saturn's rings, inventor of the pendulum clock, and originator of the undulatory theory of light.

Though busy with his Ethics and his lenses, Spinoza kept up his correspondence with various people, especially with Oldenburg. Oldenburg kept Spinoza informed of the doings of the Royal Society (which had obtained its charter in July 1662) and of the researches of Robert Boyle and others, and solicited news from Spinoza about Huygens and others, and solicited news from Spinoza about Huygens and others. But about 1665 the correspondence was interrupted. The Great Fire of London (1666) and the continuation of the war were no doubt responsible for this. In 1667 Oldenburg was suspected of espionage and clapped into the Tower of London for a time. He was released, but became nervous and cautious, so that his correspondence with Spinoza was not resumed until 1675.

From a letter written in June 1605 it appears that Spinoza was then nearing the completion of his Ethus (Correspondence, p. 202). In the following August or September, however, Spinoza informed Oldenburg that he was engaged on a theological treatise (see Correspondence, pp. 204, 206). During the next few years Spinoza was at work on his Tractatus Theologico-Politicus, which was published anonymously in 1670. Why did he put aside his Ethics in order to write a treatise on the Scriptures? The chief reason is stated on the very title-page of the Tractatus, which states that its object is "to show that not only is perfect liberty to philosophize compatible with devout piety and with the peace of the State, but that to take away such liberty is to destroy the public peace and even piety itself." Already in 1665 Spinoza

mentioned this object to Oldenburg. But he also mentioned another, namely, he wanted to clear himself of the charge of atheism which had been brought against him. It would appear that, with the completion of the Ethics in sight, Spinoza was considering the question of its publication, but found that such a step was impracticable in the then state of public opinon, which under the increasing influence of the clerics and monarchists became very intolerant and restive, as the troubles caused by the war multiplied. Spinoza consequently conceived the plan of vindicating the cause of freedom of thought in a manner that would at once serve the general interest of the Republic and also prepare the way for the publication of his own philosophy. The chief obstacle was the Calvinist clergy with their constant appeal to Scripture, which they interpreted in any manner that served their fanaticism. So Spinoza set himself the task of showing that the Bible, properly understood, gives no support to the intolerance of the clerics and their interference in civil and political affairs.

Last Years (1670-1677) .- In May 1670, shortly after the anonymous appearance of the Tractatus Theologico-Politicus, Spinoza moved into The Hague, possibly in order to be nearer some of his influential friends. He certainly needed protection. His book created a stir, and went through five editions in as many years. But it stirred a hornet's nest, and denunciations came fast and furious. At first Spinoza stayed on the Stille Veerkade, but in 1671 he went to stay with the Van der Spycks in the Paviljoensgracht near by, and remained in their house (now Domus Spinozana) to the end of his days. His work on the Tractatus involved the resumption of his earlier Hebrew studies, and it was about this time that he commenced his Hebrew Grammar. He did not, however, finish it, but returned to his Ethics, though the prospect of its publication became more and more remote. In 1672 the French invaded Holland, which was unprepared, and so suffered many disasters. The populace, fomented by the monarchists, sought a scapegoat, and murdered the brothers Jan and Cornelius de Witt. Spinoza was beside himself. He prepared a placard expressing his disgust with "the very lowest of barbarians," and was going to post it up on the scene of the crime. Fortunately Van der Spyck locked the door, and saved him from the fate of the De Witts. As it was, his Tractatus was denounced as an instrument "forged in hell by a renegade Jew and the devil, and issued with the knowledge of Mr. Jan de Witt." In 1673, while the French army was at Utrecht, Spinoza received an invitation to visit Prince Condé there. It was inspired by a Colonel Stoupe, who was in command of a Swiss regiment under Condé. Stoupe had been a Calvinist minister, and his service with Catholic France against Calvinist Holland evoked the severe censure of some of his countrymen. Stoupe was an unscrupulous adventurer, but was anxious to save appearances. So he conceived the idea of showing that the Dutch were really heretics, and for this purpose he wanted to use Spinoza as his cat's paw. He actually published later in that year a little book in which he denounced the Dutch for tolerating an atheist like Spinoza, and for making no attempt to answer his atheistical treatise. Spinoza only saw in the invitation a possible opportunity of initiating peace negotiations. So he consulted some people of authority, and, armed with the necessary safe-conducts, set out for Utrecht in May 1673. In the meantime Condé had been called away, and Spinoza after waiting for him several weeks in vain, returned to The Hague, where a suspicious rabble greeted him with scowls and stones, but did him no harm. Earlier in the same year another kind of invitation had reached Spinoza. It was an invitation from the Elector Palatine to the Chair of Philosophy in the University of Heidelburg. Spinoza declined the offer with many thanks. He had trouble enough with the clerics and theologians as a recluse, he would not court worse trouble by becoming a public character. So he stayed in The Hague, polishing his *Ethics* and his lenses, and generally practising the art of plain living and high thinking. The impression he made on the people about him may be gathered from the fact that one day his pious Lutheran hostess asked him whether he considered her religion the right way to salvation. Spinoza, of course, reassured her

In 1675 the Ethics was finished finally, and Spinoza went to Amsterdam to see whether it might be published. But rumour had preceded him. Not only the clerics and theologians but even the "stupid Cartesians" were up in arms and brewing mischief, Spinoza, accordingly, abandoned the idea of publishing it. But manuscript copies of it were in the hands of his intimate friends. Once more he turned his attention to political problems, and began his Political Treatise, which he did not live to finish.

In 1675 Tschirnhaus visited Spinoza, and also brought about the resumption of the correspondence between Oldenburg and Spinoza. In 1676 Leibniz was staying in The Hague Already in 1671 he had heard of Spinoza as an authority on optics and had sent him a copy of an optical tract. Since then he had read the Tractatus Theologico-Politicus, of which Spinoza then sent him a copy; and he had also learned from Tschirnhaus something about Spinoza's philosophy. He was evidently interested deeply. For, according to his own account, he visited Spinoza 'frequently and "conversed with him often and at great length."

The days of Spinoza were drawing to an end. The glass dust from the lenses had done its worst. He was in the last stage of consumption. About the middle of February 1677 he sent to Amsterdam for his medical friend Schuller. On Sunday, February 20, about 3 o'clock in the afternoon, Spinoza passed away in the presence of Schuller. Four days later he was buried in the New Church on the Spuy. He was only 44.

In accordance with his previous instructions his manuscripts were sent to Rieuwertsz in Amsterdam. Jelles, Meyer and Schuller prepared them secretly for the press. The Opera Poshhuma by B. D. S. (and the Dutch version, De Nagelate Schriften) were published before the end of 1677. They consisted of the Ethics, the Political Treatise, the Treatise on the Improvement of the Understanding, the Letters and the Hebrew Grammar. The Short Treatise had disappeared, but two copies of a Dutch version were recovered in 1852 and an edition was published in 1862. Two short essays on The Rainbow (1687) and The Calculation of Chances were also lost for a time, but were found and published. The Rainbow in 1862, and both essays in 1883.

For about a century Spinoza's name was anathema. His writings were indeed studied and his ideas were borrowed to a greater extent than is commonly supposed. But people dared not mention his name with respect, much less acknowledge their indebtedness to him. In time, however, things improved. Lessing, Goethe and Coleridge did most to rehabilitate his name, and others followed suit. The monument at The Hague, the Spinosahuis at Rijnsburg, and the Domus Spinosana in The Hague bear testimony to the reverence in which the memory of Spinoza is now held throughout the civilized world.

## THE PHILOSOPHY OF SPINOZA

General Account.—The pioneers of modern thought were inspired by a revulsion from the mediaeval reliance on authority, and the subordination of reason to it. The Humanists of the Renaissance attempted to vindicate the autonomy of reason as against the authority of books and institutions. This rationalist spirit affected some of the Jews of Amsterdam, and, as already remarked, brought them into conflict with established authority. It was the same spirit that brought about the crisis in the early life of Spinoza, who eventually became the prince of rationalists. He insisted that even the Scriptures must be submitted to the test of reason, and produced the most effective protest against the subordination of reason to their authority. This revolt against mere authoritarianism, however, only represented the negative side of rationalism. Important as this was, it was only preparatory to its positive aspect. The positive side of rationalism may be seen in the great classics of science in the 16th and 17th centuries-the works of Copernicus, Vesalius, Galileo, Gilbert, Kepler, Harvey, Boyle, Descartes, Huygens, Pascal, Leibniz and Newton, to mention only a round dozen of the most famous names of the period. Their discoveries were the positive results of reason, whose main function it is to trace the connections between things, to discover their laws, and to display the order which makes things intelligible. It may be said, without any disrespect for these famous men, that the positive side of rationalism also found its fullest expression in Spinoza. For he attempted a synthesis of the whole of reality. This attempt shocked some of the above-mentioned genuses, and would have shocked the rest, had they heard of it. For none of them dreamed of the possibility of bridging the chasm between the natural and the supernatural. Spinoza conceived of the whole of reality, including the human and the divine, as an organically interconnected cosmos, in which there is nothing capricious or contingent, but everything happens in an orderly manner according to law.

Spinoza arrived at his conception partly as follows. Whatever object or event be considered, it can only be explained by reference to innumerable others which condition it. Each of these is, in turn, dependent on innumerable others. Each finite thing seems to send out innumerable tendrils and derive support from all directions. Is it conceivable that reality should be composed entirely of such conditional, dependent things? Spinoza, like others, said No. There must be some self-existing, independent or absolute Being as the ground of all that is dependent. But what is the relation of this absolute Being to the world of dependent things and events? The common answer is that this absolute Being is God, an omnipotent supernatural Being who created the world out of nothing, maintains its existence, and occasionally interferes with it in miraculous ways. This conception was almost universal at that time. Newton subscribed to it. And Descartes made a special entry in his diary to record his belief in the three miracles, namely, the creation out of nothing, free-will, and the God-man. But Spinoza rejected the idea of an external Creator suddenly, and apparently capriciously, creating the world at one particular time rather than another, and creating it out of nothing. The solution appeared to him more perplexing than the problem, and rather unscientific in spirit as involving a break in continuity. He preferred to think of the entire system of reality as its own ground. This view was simpler; it avoided the impossible conception of creation out of nothing; and was religiously more satisfying by bringing God and man into closer relationship. Instead of Nature, on the one hand, and a supernatural God, on the other, he posited one world of reality, at once Nature and God, and leaving no room for the supernatural. This socalled Naturalism of Spinoza is only distorted if one starts with a crude materialistic idea of Nature and supposes that Spinoza degraded God. The truth is that he raised Nature to the rank of God by conceiving Nature as the fulness of reality, as the One and All. He rejected the specious simplicity obtainable by denying the reality of Matter, or of Mind, or of God. The cosmic system comprehends them all. In fact, God and Nature become identical when each is conceived as the Perfect Self-Existent. This constitutes Spinoza's Pantheism.

God or Nature consists of Attributes. God, as the complete system of Attributes, is absolutely infinite or complete; each Attribute is only infinite of its kind. By Attribute Spinoza means an ultimate or irreducible quality or energy. He names two such Attributes, namely, Extension and Thought, but he allows for the possibility of an infinity of Attributes. The Attributes do not belong to, but are identical with, Substance. Reality, moreover, is essentially dynamic, not static-to be is to be doing. Thus the Attribute Extension is really the whole of material energy, and the Attribute Thought is the whole of mind-energy. All material things and events are changing modes or states of Extension; and all mental events or experiences are similarly modifications or states of Thought. Each Attribute exhausts its kind of reality, is an ultimate character, activity or "world-line" of Nature, and gives rise to its entire series of objects and events in accordance with its own laws. These finite objects and events are real enough while they last, but as finite modes they change and pass; not, however, into mere nothingness, for the Attribute, of which they are states, abides. The cosmic process never stops

Spinoza's conception of Extension and Thought, or Matter and Consciousness, as concurrent Attributes or Energies of Reality cast a new light on the problem of the relation between body and soul. Indeed, it was this problem which led him to the conception of concurrent Attributes. Under the influence of Plato and of

Christianity, body and soul had come to be regarded as antagonistic to each other, and their apparently intimate relation caused much perplexity to Cartesians and others. Materialists tried to explain away the soul; idealists sought to explain away the body; the Cartesian Occasionalists fell back on the miraculous intervention of God to synchronize body and soul (that is, physical and mental processes) like the wire-puller in a Punch and Judy show. Spinoza realized the difference between the mental and the material, but rejected the Cartesian conception of their antagonism. So he did not hesitate to attribute to God both Extension and Thought. And man, a finite mode of God, is thus both physical and mental, and functions in both ways concurrently, even if each series of events is self-contained. This solution committed Spinoza to the view that all physical beings are animated, though in very different degrees; and Spinoza accepted this view.

Theory of Knowledge.-Spinoza commenced a treatise specially devoted to the problem of Knowledge. But this work, the Treatise on the Improvement of the Understanding, was never completed. In his other works epistemological discussions are intimately linked with the rest of his philosophy. Indeed, even in the Treatise on the Improvement of the Understanding epistemological views are almost inseparably connected with ethical and religious ones. That is the consequence of his characteristic conception of "Knowledge." For Spinoza "Knowledge" is "life," not in the sense that contemplation is the highest life, but in the sense that knowledge is the means of holding together the threads of life in a systematic unity that can fill its proper place in the cosmic system. In this sense the effort after the highest knowledge becomes part of the cosmic activities by which cosmic unity is maintained, and so part of the very life of God. There are two things which must be borne in mind in connection with Spinoza's conception of knowledge. The first is his insistence on the active character of knowledge. The ideas or concepts by means of which thought construes reality are not like "lifeless pictures on a panel"; they are activities by which reality is apprehended; they are part of reality, and reality is activity. The second point is that Spinoza does not divorce knowing from willing. Man always acts according to his lights. If a man's endeavours appear to fall short of his knowledge, that is only because his knowledge is not really what it is held to be, but is wanting in some respect. On the one hand, reason, for Spinoza, is essentially the "practical reason." On the other hand, the highest expression of willing is experienced in that striving for consistency and harmony which is so characteristic of reason. For Spinoza, then, as for Bacon and all the Renaissance thinkers, "Knowledge is power," but in a much deeper sense than Bacon intended.

Spinoza's account of knowledge is particularly interesting as a clue to the way in which he gradually built up his ontology. He distinguishes three ascending grades of knowledge, namely, opinion, reason and intuition. By "opinion" Spinoza means the lowest grade of knowledge in which one assents to what one hears, perceives or imagines. It is the pre-scientific stage of knowledge. Its main characteristic is that objects and events are apprehended as detached things, without any insight into their connections or laws. The second grade, or "reason," is that in which we have an insight into the connections of things and events, and their laws; it is the stage of scientific knowledge. This grade of knowledge is greatly superior to the first, inasmuch as a knowledge of their connections and laws makes things more intelligible. But even this stage is imperfect because rather abstract. It reveals the course of single threads in the fabric of reality, not the whole pattern; it traces "world-lines," but affords no synoptic vision of the cosmos as a whole. It is the function of the third grade of knowledge, "intuition," to complete the scheme. In intuitive knowledge the cosmic system is grasped as a whole. This highest stage is only possible for a mind that has been through the discipline of the rational stage. Unlike the mystics, Spinoza does not regard intuitive vision as a substitute for thought and entirely different from it, but rather as its highest fruit-it is "thoughtfulness matured to inspiration." The three stages of knowledge might be roughly compared with the three stages in the acquisition of the knowledge of a new language.

First come the separate letters of the alphabet; then combinations of letters into words and of words into sentences, etc., in accordance with the laws of grammar; lastly comes the stage when the significance of a whole sentence or paragraph is grasped at a glance. So it is with the great book of Nature. First comes the perception of apparently isolated facts and events; next comes the understanding of their interconnections and laws; finally comes the intuition of the structure and significance of the whole—the vision which sees all things in God, and God in all things.

Spinoza's theory of knowledge appears to make the ontological assumption that reality is an interconnected system. Spinoza himself regarded it as an ultimate intuition. And his theory of knowledge was in some ways a justification of that view. To realize this it is necessary to grasp the fundamental distinction which Spinoza draws between "opinion" and "reason," or perception and understanding. A percept or an image is, for Spinoza, something entirely different from an idea or concept. Conception or understanding is an activity which grasps interconnections, and has nothing to do with images as such. Perception and imagination, on the other hand, are concerned with images and not with connections. And the laws of these two kinds of activities are as different as are their objects. Perception, or imagination, is concerned with images and follows the laws of association; conception or understanding is concerned with connections and follows the laws of logic. Hence Spinoza's insistence that "we can not imagine God, but we can conceive Him" (Correspondence, p. 289). Hence also Spinoza's rejection of Baconian empiricism. From observations of particulars as such it would be impossible, according to Spinoza, to derive laws or necessary connections. The laws or general truths of science rest, in the last resort, not on their correspondence with objects of perception, but on their harmonious interconnection in a system of truths. Spinoza, accordingly, dispenses with an external criterion of truth. "The true," he maintains, "reveals itself and the false." The ultimate test of truth is more truth or more knowledge, or the coherence of all that is known. The false or untrue betrays itself by its incoherence with what is already known. In fact, Spinoza for the most part regards ideas or concepts from the point of view of their adequacy rather than their truth, in order to avoid the suggestion of a merely external correspondence such as is usually associated with the term "truth." Concepts (or "ideas" in this sense) are acts of thought by which the laws and interconnections of things and events are apprehended. They are adequate in so far as they really enable us to systematize a certain range of facts. In that case they are also true, for they agree with the facts. The primacy, however, is with the adequacy of the concept, because until we have the adequate concept we can not apprehend the facts in such a way that it can be said to agree with them, or to be true.

In the history of philosophy Spinoza was the first to elaborate the coherence theory of truth. In his time mathematics was the only science that could serve as a model of such a coherent system. Hence his addiction to the method of geometry. The significance of his use of this method has been misinterpreted. His sole aim was to express his philosophy in as coherent and objective a manner as possible. Two points should be noted in particular. In the first place, Spinoza did not suppose that science or philosophy can dispense with observation or experience. He fully realized the importance of experience in the very setting of the problems which science and philosophy seek to solve; and it is known from his letters that he carried out many chemical and physical experiments. All that he insisted upon was that science involves much more than mere observation, that it needs concepts not derived from experience. It was his intention to write about scientific method, and to show that Bacon's ideas about it were inadequate; but this was one of several plans which he did not live long enough to carry out. The second point is that Spinoza had no delusions about the conclusiveness of the geometrical method. He himself had expounded the philosophy of Descartes in that method, although he thoroughly disagreed with it.

Above all it is important to note that, for Spinoza, the highest knowledge ("intuitive" or "clear" knowledge) is something much fuller and richer than the abstract assertions usually associated with the term knowledge. In the Short Treatise (p. 69 ed. Wolf) he describes it as "feeling and enjoying the thing itself." One must try to realize his meaning by thinking of what happens when a train of thought interests a thinker so deeply as to master him completely, and he gets so absorbed in the object of his thought as to identify himself with it. If we can conjure up all this vividly and warmly, then we may realize how Spinoza came to identify the highest "knowledge" with that "intellectual love of God" in which the individual realizes himself as part of the living Universe. In this state he does not merely picture reality in an external manner, but feels its very heart throb, and feels himself as part of it. But here we are on the verge of the mystical where all but the greatest poets cease to be articulate.

Substance, Attributes, Modes .- Spinoza's ideas relating to the character and structure of reality are expressed by him in terms of substance, attributes, and modes. These terms are very old and familiar; but not in the sense in which Spinoza employs them. To understand Spinoza, it is necessary to lay aside all preconceptions about them, and follow Spinoza closely. Spinoza, as already explained, found it impossible to understand the finite, dependent, transient objects and events of experience without assuming some reality not dependent on anything else but selfexistent, not produced by anything else but eternal, not restricted or limited by anything else but infinite. Such an uncaused, self-sustaining reality he called *substance*. So, e.g., he could not understand the reality of material objects and physical events without assuming the reality of a self-existing, infinite and eternal physical force which expresses itself in all the movements and changes which occur, as we say, in space. This physical force he called Extension, and described it, at first, as a substance, in the sense just explained. Similarly, he could not understand the various dependent, transient mental experiences with which we are familiar without assuming the reality of a self-existing, infinite and eternal consciousness, mental force, or mind-energy, which expresses itself in all these finite experiences of perceiving and understanding, of feeling and striving. This consciousness or mind-energy he called Thought, and described it also, at first, as a substance. Each of these "substances" he regarded as infinite of its kind (that is, as exhaustive of all the events of its own kind), and as irreducible to the other, or any other, substance. But in view of the intimate way in which Extension and Thought express themselves conjointly in the life of man, Spinoza considered it necessary to conceive of Extension and Thought not as detached realities, but as constituting one organic whole or system. And in order to express this idea, he then described Extension and Thought as Attributes, reserving the term Substance for the system which they constitute between them. This change of description was not intended to deny that Extension and Thought are substances in the sense of being self-existent, etc. It was only intended to express their coherence in one system. The system of course would be more than any one attribute. For each attribute is only infinite of its kind; the system of all the attributes is absolutely infinite, that is, exhausts the whole of reality. Spinoza, accordingly, now restricted the term "substance" to the complete system, though he occasionally continued to use the phrase "substance or attribute," or described Extension as a substance. As commonly used, especially since the time of Locke, the term substance is contrasted with its attributes or qualities as their substratum or bearer. But this meaning must not be read into Spinoza. For Spinoza, Substance is not the support or bearer of the Attributes, but the system of Attributes—he actually uses the expression "Substance or the Attributes." If there is any difference at all between "Substance" and "the Attributes," as Spinoza uses these terms, it is only the difference between the Attributes conceived as an organic system and the Attributes conceived (but not by Spinoza) as a mere sum of detached forces. Something is still necessary to complete the account of Spinoza's conception of Substance. We have so far only considered the two Attributes, namely, Extension and

Substance or cosmic system. And using the term "infinite" in the sense of "complete" or "exhaustive," he ascribed to Substance an infinity of Attributes, that is, all the Attributes there are. whether known to man or not.

Now reality, for Spinoza, is activity. Substance is incessantly active, each Attribute exercising its kind of energy in all possible ways. Thus the various objects and events of the material world come into being as modes (modifications or states) of the attribute Extension; and the various minds and mental experiences come into being as modes of the attribute Thought (or Consciousness). These modes are not external creations of the Attributes, but immanent results—they are not "thrown off" by the Attributes. but are states (or modifications) of them, as air-wayes are states of the air. Each Attribute, however, expresses itself in its finite modes not immediately (or directly) but mediately (or indirectly), at least in the sense to be explained now. Galilean physics tended to regard the whole world of physical phenomena as the result of differences of motion or momentum. And, though erroneously conceived, the Cartesian conception of a constant quantity of motion in the world led Spinoza to conceive of all physical phenomena as so many varying expressions of that store of motion (or motion and rest). Spinoza might, of course, have identified Extension with energy of motion. But, with his usual caution, he appears to have suspected that motion may be only one of several types of physical energy. So he described motion simply as a mode of Extension, but as an infinite mode (because complete or exhaustive of all finite modes of motion) and as an immediate mode (as a direct expression of Extension). Again, the physical world (or "the face of the world as a whole," as Spinoza calls it) retains a certain sameness in spite of the innumerable changes in detail that are going on. Accordingly, Spinoza described also the physical world as a whole as an infinite mode of Extension ("infinite" because exhaustive of all facts and events that can be reduced to motion), but as a mediate (or indirect) mode, because he regarded it as the outcome of the conservation of motion (itself a mode, though an immediate mode). The physical things and events of ordinary experience are finite modes. In essence each of them is part of the Attribute Extension, which is active in each of them. But the finiteness of each of them is due to the fact that it is restrained or hedged in, so to say, by other finite modes. This limitation or determination is negation in the sense that each finite mode is not the whole attribute Extension, it is not the other finite modes. But each mode is positively real and ultimate as part of the Attribute.

In the same kind of way the Attribute Thought exercises its activity in various mental processes, and in such systems of mental process as are called minds or souls. But in this case. as in the case of Extension, Spinoza conceives of the finite modes of Thought as mediated by infinite modes. The immediate infinite mode of Thought he describes as "the idea of God"; the mediate infinite mode he calls "the infinite idea" or "the idea of all things." The other Attributes (if any) must be conceived in an analogous manner. And the whole Universe or Substance is conceived as one dynamic system of which the various Attributes are the several world-lines along which it expresses itself in all the infinite variety of events.

Having regard to the persistent misinterpretation of Spinozism it may be as well to emphasize the dynamic character of reality as Spinoza conceived it. The cosmic system is certainly a logical or rational system, according to Spinoza, for Thought is a constitutive part of it; but it is not merely a logical system-it is dynamic as well as logical. His frequent use of geometrical illustrations affords no evidence at all in support of a purely logico-mathematical interpretation of his philosophy; for Spinoza regarded geometrical figures, not in a Platonic or static manner, but as things traced out by moving particles or lines, etc., that is, dynamically.

Emergence.—A few words may be added here to indicate the merits of Spinoza's conception of the Universe in relation to the doctrine of emergent evolution as maintained by C. Lloyd Morgan

Thought. Spinoza, however, realized that there may be other and S. Alexander. (See EMERGENCE and PHILOSOPHY, HISTORY Attributes, unknown to man. If so, they are all part of the one or.) If reality is considered from the point of view of the finite modes (or Natura naturata, in Spinoza's terminology) instead of from that of Substance or the Attributes (or Natura naturans), then beginning with the simplest kinds of modes and passing on to more and more complex combinations of them, each such combination will always be something more than the mere sum of its components. To this extent something new emerges at every stage where a system is formed out of simple constituents. At a certain stage we reach the various infinite modes, then the several Attributes, and finally God. For Spinoza, however, God or the Attributes and the Infinite Modes are eternal, so that the process of evolution can only concern the world of finite modes. This kind of emergent evolution Spinoza can be said to recognize when he identifies moral progress with ever widening synthesis-"the more perfection (i.e., reality) anything has, the more does it participate also in Deity" (Correspondence, p. 151). But Spinoza's conception has an advantage over the new conception of "emergence" (including the emergence of Deity). For the new doctrine involves the conception of the emergence of something out of nothing, inasmuch as the "emergent" is not contained in the sum of its conditions, but is something new. For Spinoza, on the other hand, the fulness of reality in all its essentials is always there, and the emergence of higher modes with the increasing synthesis or "holism" (q.v.) of lower modes does not involve a miraculous emergence of something out of nothing, but merely a rearrangement of what is already real.

Moral Philosophy,-For Spinoza, reality means activity, and the reality of anything expresses itself in a tendency to selfpreservation-to exist is to persist. In the lowest kinds of things, in so-called inanimate matter, this tendency shows itself as inertia; in living organisms, it shows itself as a "will to live." Regarded physiologically this effort is called appetite; when we are conscious of it, it is called desire. The moral categories. good and evil, are intimately connected with desire, though not in the way commonly supposed. Man does not desire a thing because he thinks it is good, or shun it because he considers it bad; rather he considers anything good if he desires it, and regards it as bad if he has an aversion for it. Now whatever is felt to heighten vital activity gives pleasure; whatever is felt to lower such activity causes pain. Pleasure coupled with a consciousness of its external cause is called love, and pain coupled with a consciousness of its external cause is called hate-"love" and "hate" being used in the wide sense of "like" and "dislike." All human feelings are derived from pleasure, pain and desire. Their great variety is due to the differences in the kinds of external objects which give rise to them, and to the differences in the inner conditions of the individual experiencing them. Spinoza gives a detailed analysis of the whole gamut of human feelings, and his account is one of the classics of psychology. For the present purpose the most important distinction is that between "active" feelings and "passive" feelings (or "passions"). Man, according to Spinoza, is active or free in so far as any experience is the outcome solely of his own nature; he is passive, or a bondsman, in so far as any experience is due to other causes besides his own nature. The active feelings are all of them forms of self-realization, of heightened activity, of strength of mind, and are therefore always pleasurable. It is the passive feelings (or "passions") which are responsible for all the ills of life, for they are induced largely by things outside us and frequently cause that lowered vitality which means pain. Spinoza next links up his ethics with his theory of knowledge, and correlates the moral progress of man with his intellectual progress. At the lowest stage of knowledge, that of "opinion," man is under the dominant influence of things outside himself, and so is in the bondage of the passions. At the next stage, the stage of "reason," the characteristic feature of the human mind, its intelligence, asserts itself, and helps to emancipate him from his bondage to the senses and external allurements. The insight gained into the nature of the passions helps to free man from their domination. A better understanding of his own place in the cosmic system and of the place of all the objects of his likes and dislikes, and his insight into the necessity which rules all things, tend to cure him of his resentments, regrets and disappointments. He grows reconciled to things, and wins peace of mind. In this way reason teaches acquiescence in the universal order, and elevates the mind above the turmoil of passton. At the highest stage of knowledge, that of "intuitive knowledge," the mind apprehends all things as expressions of the eternal cosmos. It sees all things in God, and God in all things. It feels itself as part of the eternal order, identifying its thoughts with cosmic thought and its interests with cosmic interests. Thereby it becomes eternal as one of the eternal ideas in which the Attribute Thought expresses itself, and attains to that "blessedness" which "is not the reward of virtue, but virtue itself," that is, the perfect joy which characterises perfect self-activity. This is not an easy or a common achievement. "But," says Spinoza, "everything excellent is as difficult as it is rare."

Two things at least must be added to prevent a misunderstanding of this slight sketch of Spinoza's ethics. The first is that he did not teach asceticism. Circumstances compelled him to be extremely flugal and live on a few pence a day; but he affected no contempt for the joys of life. On the contrary, he urged that "it is the part of a wise man to use the world and delight himself in it as best he may, though not to satiety, for that is no delight." The second point is that Spinoza, though compelled by circumstances to live the life of a recluse more or less, laid great stress on the social character of the moral life. "Men," he says, "will find that their needs are best satisfied by mutual help, and that only by uniting their strength can they escape the dangers that beset them everywhere." He insists further that the good pursued by reasonable men is a good that may be enjoyed by all, and that the virtuous man wants no special privileges, but desires also for his fellow men whatever he desires for himself. The third point is that Spinoza's contention that the conception of goodness, like that of purpose, is inapplicable to the cosmic system as a whole does not mean that he denied the validity of the distinction between good and evil in the realm of human conduct. The notions "good" and "evil" involve the conception of an ideal that is desired but not yet realized, and the realization of which is helped by some things, hindered by others. Now the cosmic system, or God, is completely real or perfect, and therefore "beyond good and evil." But with finite modes like men it is quite different. Much can be done that really heightens or lowers human life. Whatever enriches it really is good; whatever impoverishes it really is bad, even if its badness is something negative, a defect, rather than something positive.

Political Philosophy.-Spinoza agreed with Hobbes that if each man had to fend for himself, with nothing but his own right arm to rely upon, then the life of man would be "nasty, brutish and short." The truly human life is only possible in an organized community, that is, a state or commonwealth. The state ensures security of life, limb and property; it brings within reach of every individual many necessaries of life which he could not produce by himself; and it sets free sufficient time and energy for the higher development of human powers. Now the existence of a state depends upon a kind of implicit agreement on the part of its members or citizens to obey the sovereign authority which governs it. In a state no one can be allowed to do just as he pleases. Every citizen is obliged to obey its laws; and he is not free even to interpret the laws in a special manner. This looks at first like a loss of freedom on the part of the individuals, and the establishment of an absolute power over them. Yet that is not really so. In the first place, without the advantages of an organized state the average individual would be so subject to dangers and hardships of all kinds and to his own passions that he could not be called free in any real sense of the term, least of all in the sense in which Spinoza used it. Man needs the state not only to save him from others but also from his own lower impulses and to enable him to live a life of reason, which alone is truly human. In the second place, state sovereignty is never really absolute. It is true that almost any kind of government is better than none, so that it is worth while bearing much that is irksome rather than disturb the peace. But a reasonably wise government will even in its own interests endeavour to secure

the good will and co-operation of its citizens by refraining from unreasonable measures, and will permit or even encourage its citizens to advocate reforms, provided they employ peaceable means. In this way the state really rests, in the last resort, on the united will of the citizens, on what Rousseau, who read Spinoza, subsequently called the "general will." Spinoza sometimes writes as if he upheld absolute sovereignty. But that is due mainly to his determined opposition to every kind of ecclesiastical control over the state. Though he is prepared to support what may be called a state religion, as a kind of spiritual cement, yet his account of this religion is such as to make it acceptable to the adherents of any one of the historic creeds, to deists, pantheists and all others, provided they are not fanatical believers or unbelievers. It is really in the interests of freedom of thought and speech that Spinoza would entrust the civil government with something approaching absolute sovereignty in order to effectively resist the tyranny of the militant churches.

One of the most striking features in Spinoza's political theory is his basic principle that Right is Might. This principle he applied systematically to the whole problem of government, and seemed rather pleased with his achievement, inasmuch as it enabled him to treat political theory in a scientific spirit, as if he were dealing with applied mathematics. The identification or correlation of right with power has caused much misunderstanding. People supposed tnat Spinoza reduced justice to brute force. But Spinoza was very far from approving Realpolitik. In the philosophy of Spinoza the term "power" (as should be clear from the above account of his moral philosophy) means a great deal more than physical force. In a passage near the end of his Political Treatise he states explicitly that "human power chiefly consists in strength of mind and intellect"-it consists in fact, of all the human capacities and aptitudes, especially the highest of them. Conceived correctly, Spinoza's whole philosophy leaves ample scope for ideal motives in the life of the individual and of the community.

Spinoza discusses the principal kinds of states, or the main types of government, namely, Monarchy, Aristocracy and Democracy. Each has its own peculiarities and needs special safeguards, if it is to realize the primary function of a state. Monarchy may degenerate into Tyranny unless it is subjected to various constitutional checks which will prevent any attempt at autocracy. Similarly, Aristocracy may degenerate into Oligarchy, and needs analogous checks. On the whole, Spinoza favours Democracy, by which he meant any kind of representative government. In the case of Democracy the community and the government are more nearly identical than in the case of Monarchy or Aristocracy; consequently a democracy is least likely to experience frequent collisions between the people and the government, and so is best adapted to secure and maintain that peace which it is the business of the state to secure.

Bible Criticism .- Spinoza was not only the real father of modern metaphysics and moral and political philosophy, but also of the so-called higher criticism of the Bible. This part of his work was incidental to his plea for freedom of thought and speech. His Tractatus Theologico-Politicus undertook to show that the Scriptures properly understood gave no authority for the militant intolerance of the clergy who sought to stifle all dissent by the use of force. To achieve his object, Spinoza had to show what is meant by a proper understanding of the Bible. And this gave him occasion to apply criticism to the Bible. To appreciate his services in this connection it must be remembered that his age was remarkably lacking in historical sense, especially in matters relating to religion. Saintly contemporaries like John Bunyan and Manasseh ben Israel made the most fantastic use of Scripture texts; while militant clerics, relying on the ignorant bibliolatry of the masses, misapplied Bible texts to gain their ends. Spinoza, who permitted no supernatural rival to Nature and no rival authority to the civil government of the state, rejected also all claims that Biblical literature should be treated in a manner entirely different from that in which any other document is treated that claims to be historical. His contention that the Bible "is in parts imperfect, corrupt, erroneous, and inconsistent with itself, and that we possess but fragments of it" roused a great storm at the time, and was mainly responsible for his evil repute for a century at least. Nevertheless, the intelligent world has gradually come round to his views, and has learned to agree with him that the real "word of God," or true religion, is not something written in books but "inscribed on the heart and mind of man." And many ministers of religion now praise Spinoza's services in the correct interpretation of Scripture as a document of first rate importance in the progressive development of human thought and conduct.

Bibliography:—Biographies: (M. Lucas) The Oldest Biography of Spinoza, edited, translated and annotated by A. Wolf (1927); A. Wolf, Spinoza, edited, translated and annotated by A. Wolf (1927); A. Wolf, Spinoza, this Life and Treatise on God and Man (1920); J. Freudenthal, Das Leben Spinozas (1904, 1921), and Die Lebensgeschichte Spinozas (1920). Works: The best edition is Spinoza Opera (1921). Translations: An English translation of the complete works of Spinoza (1921). Translations: An English translation by A. Wolf is in course of preparation; the volume containing the complete Correspondence of Spinoza was published in 1928. Of other English translations the following are the most important: Spinoza's Chief Works translated by R. H. Elwes (2 vols., 1823-84, etc.); Ethics translated by Hale White and A. H. Stilling (1899); A Short Treatise on God, Man and his Well-being translated by A. Wolf (1910). The best French translations are those by E. Saisset (3 vols., 1861) and Ch. Appuhn (4 vols., 1904, etc.). The best German translations are those by B. Auerbach (2 vols., 1871), and by O. Baensch, C. Gebhardt and others (3 vols., 1904, etc.). Books on Spinoza's Philosophy, etc. The following are the most important: F. Pollock, Spinoza, His Life and Philosophy (1880, 1890, 1911); Martineau, A Study of Spinoza (1883, 1895); J. Caird, Spinoza (1888, 1901); H. H. Joachim, A Study of the Ethics of Spinoza (1907); R. A. Duff, Spinoza's Ethical and Political Philosophy (1903); L. Roth, Spinoza, Descartes, and Maimondies (1924); J. A. Gunn, Benedict Spinoza (1925); contains a bibliography; R. McKeon, The Philosophy of Spinoza (1928); L. Roth, Spinoza (1900); J. Freudenthal, Spinoza (1900); C. Problem mortal active to Camera, Delic Lehre Spinozas (1901); J. J. Freudenthal, Spinoza (1902). Of German Books the most important are: D. Camera, Die Lehre Spinozas (1932) and Leben und

SPINY SQUIRREL, a group of African ground squirrels, characterized by the spiny nature of the fur. They form the genera Xerus, Euserus, Allantoserus and Geosciurus, being characterized by the small size or absence of the ears, and the long, nearly straight, claws. Typical spiny squirrels live in clefts or holes of rocks, or in burrows. (See RODENIA.)

SPION KOP, a mountain in Natal on the N. Tugela river, and 24 mi. W.S.W. of Ladysmith. It was the scene of a battle in the Transvaal War (see South African War and Ladysmith).

SPIRAEA, a much cultivated genus of shrubs of the rose family (Rosaceae, q.v.), comprising about 80 species, natives mostly of the northern hemisphere. They are slender shrubs, 2 to 8 ft. high, usually with simple leaves and small white, pink or reddish flowers arranged in dense showy clusters. S. salicifolia (queen of the meadow) occurs in England and Scotland. S. latifolia (meadow-sweet), S. alba (white meadow-sweet) and S. tonentosa (hardnack, q.v.) are representative species of E. North America. S. douglasi (western meadow-sweet) occurs on the Pacific coast. Among the best-known cultivated forms are S. prunifolia (bridal-wreath) and the popular hybrid S. vanhouttei. There are dozens of named forms, commonly called spiraeas, and some are forced for early spring bloom.

A few of the so-called spiraeas belong to the genus Astilbe of the family Saxifragaceae.

SPIRE, in architecture, a steep, pyramidal form, crowning a tower. The origin of the form was the simple, four-sided, pyramidal roof frequently erected over Romanesque towers, as in many crude 11th century examples in Normandy, some of the Italian campaniles of the 11th and 12th centuries, and many German Romanesque towers, mostly of the 12th century. This form is abrupt and stunted and may easily be ungraceful, and various experimental attempts were made to soften the line. Thus the late 11th century tower at Le Puy en Velay has the successive stages of the tower receding and broken up by projecting bays on the sides. Furthermore, the pyramidal roof itself is

A. ....

decorated with corner finials and small, round-headed dormers. In Germany the form was varied by ending each face of the square tower in a gable, the plane determined by adjacent gable slopes establishing the slope of the pyramid, as in the square tower of the abbey church of Laach (c. 1156). The pleasanter effect of the octagonal spires over octagonal towers, like another of the towers at Laach, or the older of the two towers at Mainz (late 12th century), led to attempts to combine an octagonal spire with a square tower. This was accomplished in various ways, one of the simplest being the so-called broach spire, in which small, triangular planes of a less steep pitch than that of the spire proper occur at the bottom of the corner spire faces, with their lower points coinciding with the corners of the towers, as seen in the 12th century church of S. Columba at Cologne.

A more developed form of broach spire lies in the substitution of a small pyramid at the bottom of the corner faces, instead of the triangular plane. This is a type which became common in English Gothic spires. It may be described geometrically as the intersection of a four-sided pyramid of low slope by an eight-sided pyramid of steep slope, as in the 14th century spire of St. Mary's at Stamford. A more elaborate method of softening the junction between square and octagon was to carry the corner faces down unbroken to the top of the tower and fill the triangular corners thus left with decorative finials. An early example is the crossing tower of the church of S. Ours, at Loches, France (12th century).

In the south-west tower of Chartres cathedral (end of the rath century) a further advance is made in connecting tower and spire, by adding high, gabled dormers on the faces of the spire, over the centres of the tower faces, as well as richly developing the conner pinnacles. In the spire at Senlis cathedral (13th century) a vertical, octagonal stage, or lantern, is placed between the square tower and the octagonal spire. The corners of the square tower are occupied by pinnacles and eight slim dormers surround the spire base. The edges of the Chartres and Senlis spires are decorated with projecting roll mouldings, and those at Senlis are further enriched by crockets which form an admirable fretting of the silhouette. It is probable that similar crocketed spires were almost universally intended over the great towers of most of the French cathedrals. The towers at Laon, for instance, were once so crowned and spires at Reims and Amiens were begun.

Gothie CHmax.—It was in Normandy, England and Germany that Gothic spire design reached its climax. Particularly famous are the spires of S. Sauveur at Caen (14th century); S. Fierre at Caen (1308) and the magnificent group of spires at Coutances cathedral (13th century), in which the spire dormers and the corner pinnacles are treated with the utmost richness and the sense of height and slimness emphasized in every possible manner. The customary lavishness of the French Flamboyant style is magnificently illustrated in its pierced and intricately traceried spires. The two most remarkable examples are the northern spire of Chartres cathedral (1506–13), by Jehan Texier, and the so-called Tour de Beurre (c. 1520) of the cathedral at Rouen.

Spires of a simple type crown many of the Italian campaniles, and during the 13th, 14th and 15th centuries, spires and lanterns were frequently added to earlier towers. In neither Italy nor Spain, however, was the highly developed spire a native form, and Italian spires were simple, slate, tile or metal covered, pyramidal or conical roofs of timber. Burgos cathedral is unique in Spain in possessing two western spires of intricate, open-work masonry, which date from the 15th century. These, however, are known to have been designed by a German architect.

German luxuriance, which had already appeared in the numerous varieties of timber spires used on the Rhenish Romanesque churches, found equally congenial expression in the stone spires of the Gothic period. The early, simple type is seen in the solid spires of S. Elizabeth at Marburg (not completed until the middle of the 14th century but probably from a 15th century design). The cathedral at Freiburg has a spire (1270–88) which is of a new and infinitely richer type. The low, square tower carries a high, octagonal lantern, each side of which is capped by a slim gable and filled with delicate tracery, the corners of the square being filled with rich, triangular pinnacles, one of which is con-

tinued up as an open, spiral staircase, giving access to the upper portion. The spire rises above the lantern, a mere cage of open-work tracery, with crocketted edges, amazingly light and delicate in effect. Somewhat similar, although even more intricate in their pierced stone-work are the western spires of Regensburg cathedral (late 15th century), by Roritzer. These open-work spires became the rule in Germany, as illustrated in the intricate cage of Strasbourg cathedral (spire, 1435); the west towers of Cologne cathedral, hullt in the 19th century from mediaeval drawings; the overcomplicated lace-work of the cathedral at Vienna (1433) and the spire at Ulm, over 500 ft. high, built in the last years of the 19th century, from Isth century drawings.

The spire of Oxford cathedral (1220) is a perfect example of the Early English spire type: it is octagonal, has a marked entasis or convex curve, and is decorated with dormers on each face and corner pinnacles. The great spire of Salisbury cathedral (1250), 406 ft. high, shows the tremendous aesthetic advantage of the greater steepness there present, which became the rule in the later English spires. During the Decorated period it became customary to finish the top of the tower with a parapet, either battlemented or of pierced tracery, and to set back the base of the spire behind the face of the wall. With this change the use of broaches disappeared and tall, corner pinnacles, sometimes supported on corner buttresses, filled the tower corners. An early example of the parapeted tower with a spire, in which broaches remain and the corner pinnacles are raised up to the top of the broach, is that of Ashbourne church, Derbyshire (14th century). Among the loveliest of Decorated spires are the two western spires of Lichfield cathedral, with heavy but effective, corner pinnacles. The highly developed type of spire with corner pinnacles and a parapet below can be seen in St. Peter's, Kettering, and Sts. Peter and Paul, Oundle (both in Northamptonshire), both of the Perpendicular period. In other examples a little flying buttress connects the corner pinnacles with the face of the spire, as in the exquisite Perpendicular spire of Louth church, Lincolnshire. Many Perpendicular spires are often ornamented with crockets up the angles.

Renaissance.-The spire was a form never thoroughly absorbed by the Renaissance, which preferred domed lanterns crowning towers. Nevertheless, during the 17th century in Germany, most effective, fantastic, spire-like forms were developed. These, based partly on Italian Baroque prototypes, usually had profiles of broken concave and convex lines, crowned at the top with a sort of onion dome, the whole rising to a considerable height, and, in imaginative quality, far surpassing any of the Italian examples. It is such fantastic spires crowning the simple towers of village churches, which give much of their character to the little towns of south Germany and Austria. At the same time, in England, the spire idea was receiving a much simpler and more straightforward, and equally effective, Renaissance expression, through the efforts of Sir Christopher Wren and his followers, particularly in the churches built after the Great Fire of London in 1666, such as St. Martin's, Ludgate hill, St. Mary-le-Bow and St. Bride's, Fleet street, all by Wren. St. Mary-le-Strand (early 18th century) and St. Martin's-in-the-Fields (1721-1726) both by Tames Gibbs, which simplified and refined upon their Wren prototypes, are very successful.

Even more effective are many American colonial spires, which, although originally based upon the work of Wren and Gibbs. achieved a fresh beauty through still further simplification. Particularly noteworthy is the type in which a small, octagonal, arcaded lantern crowns a simple, square tower and carries, usually above an attic, a simple, slim, white spire, as in the Old South Meeting House, Boston (1729) and the extremely delicate, white, wooden steeple of the church at Farmington, Conn. (c. middle 18th century). Such steeples as that of S. Paul's chapel, New York (c. 1767), Christ church, Philadelphia (1754) and S. Michael's, Charleston, S.C. (1742, occasionally attributed to James Gibbs himself), although more monumental in treatment and more English in effect, still retain the characteristic American delicacy. This trend toward the more slender and attenuated proportions reached its climax in the exquisitely light spire of Park street church, Boston (1819), by Peter Banner. (For

bibliography see Gothic Architecture.) (T. F. H.)

SPIRE LIGHT, the term given to the windows in a spire which are found in all periods of English Gothic architecture and are an important feature in French spires. They are not glazed, and, if of large size, sometimes have transoms to strengthen the mullions.

SPIRES: see Speyer.
SPIRITS. The word spirits is most frequently used as a designation for alcoholic beverages, more particularly of the ardent type which owe their strength to distillation. This process is one commonly used to separate the more volatile from the less volatile components of solutions, simultaneously concentrating the former in the distillate and leaving the latter also in a more concentrated form as a residual solution. In the preparation of spirituous beverages, the distillate is the portion of greater value, and the residue is often a waste product rather than a material of commercial utility: this is not invariably the case with products of distillation, for, apart from alcoholic beverages, there are instances where the residue is the substance of greater interest, while the distillate may or may not be of sufficient value to warrant the precautions taken in its recovery. Again, the volatiles might be nuisances or even dangerous if they were simply boiled off without any precautions being taken to condense them into a liquid form, which may be more convenient for disposal, if not for reutilization.

The major components of distilled spirituous beverages are alcohol, the active intoxicating principle, and water, the diluent. Mixtures of these two substances in their purer forms would not, however, afford drinks of any appreciable attraction, and it is from small quantities of substances having more complex nature that the beverages derive their individual characters. The effectiveness of the minor constituents, which include higher alcohols, aldehydes, ethers, esters, volatile acids and other organic compounds, is in most cases out of all proportion to their quantities, and these subsidiaries can, accordingly as they may be excessive or otherwise in amount, invest the liquors with coarser or feebler flavours than may be desired. The aim of the manufacturer has been from time immemorial to produce a spirit of satisfactory strength with just sufficient of the flavouring agents to yield a palatable product. This is usually attained with a pot still.

Distilling in Antiquity.—The evaporation of the alcohol out of the various beers, wines and such liquors and its reclamation in liquid form gave rise to interesting developments in the forms of distilling apparatus. Originally a cool surface was held in the hot vapours from the boiling liquor and periodically cleared of the fluid which collected upon it. Pliny mentions the hanging of fleeces over boiling resin to collect turpentine, and Alexander of Aphrodisias records that sailors boiled sea water and collected sweet water by hanging sponges in the steam. This expedient seemed to have been superseded, for the sake of more efficient collection, by the use of a bowl filled with cold water, from the outer surface of which the condensate dripped into a vessel within the still pot (Tibetan and Bhutan style) or, according to Peruvian practice, into a tube which transferred it to an external receiver. By leading the vapours from the still pot through a pipe into a receiving vessel, where they condensed naturally, the Kalmuck Tatars made another evolutionary step, while the Sinhalese in their warmer climate augmented the effectiveness of this arrange-

FIG. 1.-ANCIENT FORM OF STILL, USED IN TIBET

ment by immersing the receiver in cold water. The natives of Tahiti sought to chill the vapours before they reached the receiver by cooling the connecting pipe and so invented the precursor of the Dariot or Liebig condenser, which has in modern times been modified into many ingenious forms. The Alexandrians elaborated the primitive cold surface into a more complex still head or alembic with an annular gutter by which the distillate was led

SPIRITS 241

to an external receiver; the addition of supplementary water cooling to this head exemplifies the form of the Mysore still which was reinvented in later years in the guise of Kodak and Sheldon condensers.

Modern Types of Still.—Simple pot stills constructed on the lines of the Tahiti model are used even now in France for brandy

FIG. 2 .-- ANCIENT FORM OF STILL USED IN PERU

and in Scotland and Ireland for whisky, but the pot is usually surmounted by a bulbous head or capital for the purpose of freeing the rising vapours from spray, which would contaminate the distillate, and of avoiding the risk of priming or blowing liquid over with the vapour. In some Irish installations, however, the still is connected to the condenser through a cooled lyne arm which partially condenses the less volatile components of the vapour, these being returned to the still pot while the more volatile substances pass on to the condenser. This is a primitive type of fractionator or rectifier. Some of the French brandy stills have a two-compartment bulbous vessel between the still and the condenser: one compartment contains the next charge to be transferred to the still, while in the other the less volatile substances are partially condensed, as in the lyne arm of the Irish still, but the heat lost by the vapour in becoming liquid is gained by the wine about to be run into the pot. This heat interchanger is an economizer of fuel. The pot stills used in the whisky distilleries of Scotland become more complicated, with two or more vessels between pot and condenser; they are retorts (the "eggs" of Eduard Adam's patent of 1801, inspired by the Woulf's bottle), or rectifiers, which return less volatile components to the pot and pass on the lighter fractions toward the condenser. These operate by virtue of the latent heat liberated by the steam during its condensation, evaporating spirit out of liquid which has already condensed. Wash heaters or heat interchangers are also incorporated.

In 1944 there were designed types of pot stills suggested by the admiralty for use in lifeboats and for other purposes, including the recovery of spirit which has become diluted in the performing of technical operations. In these models no attempt is made to fractionate the distillate, but heat is economized as much as possible by heat interchangers between boilers and condensers and in the boiler drainage tubes, a constant flow of waste liquor from the pot being maintained in order to keep the boiler clean.

The idea of the charge heater of the French brandy still is not modern, for a similar design appears in a publication by H. Braunschwick in 1512, the arrangement being shown as surmounting the boiler; it thus appears as the precursor of the modern refluxing fractionating column or still head which, in all its complicated modifications, is designed to give the maximum separation of volatile components in the course of a single operation. These improvements have been so effective that fractionating columns have become quite useful instruments in an analyst's equipment.

It is by an easy progression from the fractionating column, via

Charles Louis Derosne's, J. H. L. Pistorius' and J. J. Saint-Marc's designs, that Aeneas Coffey's and other patent stills were developed; these offer an efficiency in industrial operations which is unattainable on the laboratory scale so far as economical operation is concerned. The subject of Coffey's patent of 1832 consists of two towers which are essentially large-scale fractionating columns and heat interchangers. The first tower, called the analyzer, may or may not surmount a boiler and is a fractionating column into which steam is blown at the bottom and the alcoholic liquor or wash injected near the top. The tower is packed with perforated plates through which the steam blows, preventing the wash from passing from one plate to the next below through the perforations; when any upper plate carries sufficient liquor, the excess flows through a short pipe standing in a cup which rests on the plate below. This serves both as weir and as an obstruction to the steam which can then only rise through the tower by bubbling through successive layers of liquid. The heat evolved in the condensation of some of this steam evaporates or strips the alcohol out of the wash, and the mixed vapours pass to the base of the next tower or rectifier, which contains a similar arrangement of plates to that of the analyzer and a pipe lying in sinuous coils between each pair of plates. This pipe serves two purposes: it acts both as a heat interchanger, by warming the wash which passes through on its way to the top of the analyzer and as a cooler, by causing partial condensation of the vapours passing through the column. The condensate loads up the plates and fractionating is taken a stage further by removing the less volatile constituents, which are collected as fusel oil and water from the base of the tower. Finally, the vapour issuing from the top of the column is condensed as high strength spirit containing few impurities and known as plain, neutral, silent, velvet or Cologne spirit. Being almost flavourless and strong, plain spirit alone is of no value as a beverage, but some of it is used to dilute other alcoholic drinks which are too highly flavoured, to prepare compounded spirits and to fortify weak wines; the rest of it finds an outlet in industry.

Much industrial equipment has an important peculiarity: a refrigerator, which usually has the form of a simple worm condenser, is interposed between the condenser proper and the receiver; its purpose is to complete condensation and to chill the distillate, so reducing the vapour pressure of the latter that loss by evaporation is minimized.

Application of Distillation in Industry.—It should be noted in passing that the perfecting of the distillation plant, though closely connected through the ages with the production of spirituous beverages, has been in the 20th century a considerable asset to coal tar, oil and other industries; developments in these fields have continued at an amazing pace, so that mixtures of volatile substances can easily be analyzed into fractions whose condition approaches a state of purity.

FIG. 3,-STILL OF ANCIENT TYPE AS USED IN TAHITI

An interesting application of distillation equipment is exemplified in the apparatus used to fractionate liquid air at low pressures in order to obtain oxygen in such large quantities that the needs of industry can be economically satisfied. Another case is the provision of fractional distillation in the arrangements of certain

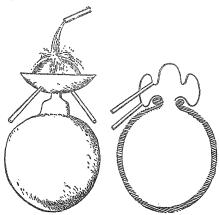

FIG. 4.--ANCIENT STILL USED IN SOUTHERN INDIA (MYSORE STILL)

refrigerators claimed to possess no moving parts; operation is possible by evaporation of a volatile liquid into a circulating gas stream, absorption from this into a less volatile liquid and fractionation of the resultant solution to separate the volatile liquid again, the operations being concurrent and continuous.

In the British Isles, where the revenue duties on potable spirits are high, the board of customs and excise have a lively interest in the existence of stills and none are allowed to be established unless a license has been issued or unless permission has been granted to possess or use a still without license. All such installations are subject to inspection at any time by excise officers in order that the clandestine distillation of potable spirits may be prevented. Illicit stills are therefore not common.

The distilled beverages which may properly be designated as spirits are, among English-speaking peoples, brandies, gins, rums and whiskies, but there are others known to other nationalities. The history of these substances is obscure, but a brief tabulation of some of them with their origins may be of interest.

B.C.	Country	Raw material	liquor	Distillate

1200	Spain	Grapes	Wine	Aqua vini
1300	France	a	и	Cognac
1500	Scotland	Malted barley	"Beer"	Aqua vitae Whisky

In general, the raw material is a sugar such as is to be found in honey, ripe fruit, sugar cane, beetroot, milk, or a substance of an amylaceous nature which may be easily converted into a sugar. Fortunately this change is simply effected, for some of the active agent is already present in ccreals containing the necessary starch, or is easily developed in them; where it is absent, as in potato starch, a suitable cereal can be added.

Action of Enzymes.—The active agents which break downstarches into sugars and sugars into alcohol are known as enzymes and are generally water-soluble nitrogenous compounds having something of the nature of albuminoids. They behave rather like catalysts in that a very little of them will cause a fundamental change in large quantities of the material being processed; they are easily poisoned by certain substances such as hydrocyanic

acid, mercury salts and formalin, are sensitive to temperature variations (being rendered inactive in certain conditions) and are specific in action in that each is effective for certain classes of substance only. They convert complex insoluble material into simpler assimilable substances: the enzyme amylase, for instance, will reduce starch to dextrin and then to the sugar maltose; the enzyme maltase will reduce maltose to the simpler sugar dextrose, and finally the enzyme zymase will ferment the dextrose to alcohol and carbon dioxide; all of these changes take place easily in aqueous solution. The presence of amylase and maltase in cereals, particularly if germination has begun, and the presence of zymase in yeast ensure that all the necessary materials for the manufacture of spirit are readily and economically available. There are, of course, other enzymes-sucrase, present in yeast and malt, will break down cane sugar to invert sugar; lactase will hydrolyse milk sugar to simpler fermentable sugars; cytase will disintegrate cellulose; lipase will degrade fats, and so on.

Processing.—In the case of cereals, processing is begun by grinding the grain and heating it with water to gelatinize the starch and so form the mash. This is cooled to a temperature between 50° and 60° C. and saccharified by adding ground malt, a preparation obtained from a cereal such as barley which has been moistened, allowed to germinate, dried, kilned (over peat fires for Scotch whisky) and ground; in this powder there are sufficient amylase and maltase to break down not only the start of the malted cereal but also that of the other amylaceous material. The liquid, now known as wort, is cooled to about 20° C. and pitched with yeast to initiate fermentation, a process which produces a wash ready for the stills.

Saccharine materials do not need the assistance of malt to prepare them for fermentation and the simpler ones, such as honey and grape sugar, can be fermented without any preparation other than solution in water, but the more complex sugars, such as cane sugar (molasses), beet sugar and many fruit sugars, need to be simplified or inverted before the yeast can attack them; the enzyme effecting this change, invertase or sucrase, is fortunately present in yeast and malt, and its action can proceed simultaneously with fermentation.

Yeast, the fermenting agent, is a budding fungus or unicellular vegetable organism without chlorophyll belonging to the genus Saccharomyces; of its many kinds, those of interest to brewers and distillers are of the species cerevisiae. In this species there are many varieties not always containing the same enzymes, and behaving differently toward various sugars. Charles Simmonds gives an interesting synopsis in his book Aicohol,

Yeast.—The whole story of yeasts and moulds, their active principles and the manner of utilizing them is a long and fascinating one which has occupied the attention of many investigators since the publication of the researches of Louis Pasteur, the real pioneer of the science of modern brewing; those who have more

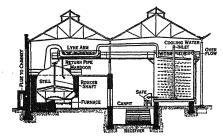

FIG. 5.—DIAGRAM OF SINGLE TYPE OF IRISH POT-STILL PLANT (JOHN JAMESON'S DISTILLERY, DUBLIN)

than a passing interest will find the records of Pasteur's work a good foundation for serious study.

The wash or the wine is conducted to the stills where, in the

case of the pot stills, two or more successive distillations are performed to produce a spirit of the desired strength; in the case of patent stills the process is completed in one operation. The resultant liquid is colourless and, in all products other than those from the plain spirit patent stills, rather harsh or raw in flavour: it should be matured. To this end the distillate is stored for at least four years in oak casks which may previously have contained sherry or which may have been charred internally, if there are none available that have already been used for the maturing process. Old casks, particularly those which have contained good vintages of choice blends and which have been well used, are esteemed of high value; Limousin oak is thought to be the best wood for their construction. During the storage period, considerable changes among the secondary constituents occur. While the concentration of the alcohol itself decreases, the proportions of volatile acids, aldehydes, higher alcohols and esters increase. but it should be remembered that some of the increase may be only relative in consequence of the evaporation of alcohol. The liquid also absorbs colouring matter and flavoursome ingredients, such as tannin, from the wood of the casks. After four years the change is not so rapid, although the mellowing tendency is still marked. Cask storage is extremely important, because only by this means can the finest maturing be achieved. In other containers, such as bottles, there is scarcely any noticeable change.

Potable Spirits.-Of the main classes of potable spirits there are many varieties. Commercially, the most important brandy is cognac made from the grape wines of the Charente and Charente Inférieure; this is the only brandy which in France can legally be named cognac, and the convention is generally respected elsewhere. Incidentally it is rather curious that this best brandy is obtained from a wine which to the palate appears to be of poor quality. Other French grape brandies are designated eaux de vie, with either the name of the district of origin or the name of the raw material from which they are made; for example, eaux de vie de marc is made in Burgundy from pomace or marc, the grape residues which are rejected in the manufacture of wine. United States brandy is made from Californian wines, and other grape brandies of good quality have their origin in Africa and Australia. Apple brandy or apple jack is distilled from hard cider in the eastern U.S., while peach brandy from fermented peach juice solves a problem of unmarketable peach crops in the southern states; blackberry brandy is also fairly common in the U.S. Huckleberries and raspberries are the raw materials for their respective brandies in the Black Forest district and gentian root serves a similar purpose in south Germany and Switzerland. In these same districts and in the south of France wild cherries provide the saccharine material from which real cherry brandy, arrack, or kirschwasser, is prepared. In Britain and elsewhere a maraschino cherry brandy and a blackberry brandy are extensively marketed; these are not true brandies but rather compounded spirits, liqueurs or bounces containing fruit juices, sugar and neutral spirit or mild brandy. (See BRANDY; LIQUEURS.)

Gins are generally patent still spirits, doubly rectified, sweetened or unsweetened and flavoured with the volatile constituents of juniper berries, angelica, almonds, calamus, cardamons, cassia, coriander, fennel, grains of paradise, licorice, orris and turpentine; the flavouring is usually added to the liquid before final distillation. Geneva (corrupted from "jenever," meaning juniper), Hollands and schnapps are Dutch gins, pot-stilled from maltwine, rectified and flavoured. Old Tom is a sweetened gin containing 1% to 6% of sugar. Plymouth gin contains a little ether, because a small quantity of sulphuric acid is added to the purch before distillation. (See Gray.)

wash before distillation. (See Gin.)

There are not many varieties of rum, but they are characteristic. (See Rum.) Demerara rum is prepared from a rapidly fermented dilute solution (sp.g. 1.060) of molasses, slightly acidified with sulphuric acid to liberate organic acids and inhibit bacterial action. Jamaica rum is distilled from a slowly fermented wash (sp.g. 1.078-1.096) made from molasses, soured skimmings from sugar pans and dunder or the residues in the still pots from previous operations; a certain bacterial action is encouraged in the fermenting liquor and the resulting spirit has a high content

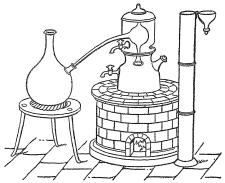

Fig. 6.—DESIGN FOR DISTILLING APPARATUS FROM BRAUNSCHWICK'S DAS BUCH ZU DISTILLIEREN (1512)

of volatile acids and esters. German rum is the result of a special fermentation to provide large quantities of esters and secondary constituents with a strong flavour in consequence; it is intended for mixing with neutral spirit to provide imitation rum. Pot stills are used in rum distillation to retain as high a proportion as possible of the secondaries, but patent stills are also employed to produce a so-called white rum, which is really a neutral spirit, and from this large quantities of gin are manufactured.

Whiskies are obtainable in many varieties. In the U.S. corn whisky is made from maize alone, part of the cereal being sprouted to develop the amylase necessary for the saccharification of the starch. Malt whisky is similarly derived from malted barley only, and rye whisky is, as its name implies, produced from rye. Bourbon whisky is prepared from mixed cereals such as maize 65%, rye 20% and barley malt 15%. Apart from variants in the raw materials, there are two methods of mashing which can yield products of diverse flavours. In sour mash some of the residues from a previous fermentation, and sometimes spent lees from the stills, are added to the new mash, giving rise to acidic conditions under which fermentation is allowed to proceed for some 48 hours. Sweet mash is prepared from fresh cereals and malt only and the succeeding fermentation is extended up to 72 hours. Irish whisky is usually a pot-still product and is derived entirely from malted barley or from a mixture such as 50% malt and 50% cereals, four-fifths of the latter being barley and the remainder oats, wheat and rye. Scotch whiskies are obtainable in half a dozen types, of which there are many blends; cambus or grain whisky is a patent-still product; i.e., neutral spirit; the other types are pot-still goods and derive their characters from the malts used in their preparation: a malt which has not been kilned in peat smoke yields a grain and malt whisky; Campbell town whisky is derived from a malt which is mildly peat-smoked, while Lowland, Highland and Islay are successively stronger in peat smoke flavour. The peat necessary for this kilning of the malt is carefully selected and generally subjected to a routine of controlled fermentation and drying to develop the properties most desirable in it. (See Whisky.)

Compounded Spirits.—Another class of well-known alcoholic beverages is that of the compounded spirits. These are extracts, infusions and mixtures concocted from one or more of the potable spirits or diluted plain spirits with flavourings derived from fruits, herbs and spices. They are sometimes sweetened and often coloured, and include liqueurs (foreign goods) such as absinthe, anisette, bénédictine, chartreuse, crème de menthe, curaçao, künnel, maraschino, noyeau and vermouth; cordials (British products) such as cherry brandy, cherry whisky, clove cordial, ginger cordial, orange bitters, peach bitters, peppermint cordial and sloe gin; ratafias, which are fruit extracts not subjected to distillation; and also gin and imitation rum.

General Properties of Spirits .-- Apart from aroma, which is usually caused by small quantities, even traces, of strongly flavoured secondaries, essences or extracts, the general properties of spirits are those of aqueous solutions of ethyl alcohol, a colourless mobile liquid with a slightly higher viscosity but a lower surface tension and a much lower electrical conductivity than water. It is neutral in character, but can act either as a base, by combining with acids to form esters or ethereal salts, or as an acid, by combining with strongly basic metals to produce ethylates. It can burn in air with a blue nonluminous flame and is decomposable in the absence of air at high temperature, particularly in the presence of catalysts such as powdered aluminum, zinc dust, reduced nickel, thoria or alumina, releasing hydrocarbons and other simple compounds. On the other hand, contact with strong oxidants will result in the formation of aldehyde. acetic acid and even of carbon dioxide and water. Absolute alcohol is hygroscopic and miscible with water in all proportions, with an accompanying evolution of heat and a contraction in total volume which is most noticeable when 52 volumes of alcohol are mixed with 48 volumes of water at 20° C., to yield 96.3 volumes when temperature is restored to 20° again. Specific heat is about twothirds and thermal expansibility is five and a half times that of water at 20° C.; these characteristics, coupled with the possession of a low freezing point (-130° C.), render the liquid a suitable filling for certain ranges of thermometers. The boiling point of alcohol is 78.3° C., heat of vaporization is only about 2/11 of that of water, vapour pressure at ordinary temperatures is about 21/2 times as great; these facts are reflected in the relatively easy separation of alcohol from water by fractional distillation-up to a certain limit-and in the lesser known data of flash points, which are of great importance in connection with fire risks during storage and transport. According to von Schwartz, the following temperatures may be taken as a guide to the flash points of various alcoholic liquors:

Ethyl alcohol 100% 51° F.
Ethyl alcohol 95% 57° F.
Rum, arrack and cognac 77° F.
Whisky 82° F.
Hollands gin 89° F.
Sherry and port wine 120° F.

These temperatures must be regarded with a certain amount of reserve, since they are dependent upon spirit strength, which has a considerable range of variation in each type of beverage. Aqueous mixtures at any given pressure boil at various temperatures, according to the alcohol content, but the lowest boiling point is that of a solution containing 4.43% of water, the mixture of constant boiling point; i.e., 79.15° C. at 760 mm. as against 78.35° C. for pure alcohol. This is an azeotropic mixture-one which distils at a constant temperature lower than the boiling points of its components, without change of composition, when the pressure is kept constant. Constitution varies with pressure, and at pressures below 70 mm, of mercury the alcohol-water azeotrope does not exist; it is therefore possible to obtain absolute alcohol by vacuum fractional distillation, although in practice the separation is not easily effected because of the small difference between the boiling points of the absolute and aqueous alcohols. The spirit produced from wash by any simple distillation process at ordinary atmospheric pressures can never be pure alcohol, but the latter may be obtained by drying out the water with powerful dehydrating agents before a final distillation, by vacuum fractional distillation or by adding to the aqueous alcohol sufficient of another liquid, such as benzene, or a chlorohydrocarbon to form a triple azeotrope boiling at a still lower temperature and fractionating: in this instance, first the triple azeotrope containing the undesired water and then a double azeotrope containing the excess of the added substances are eliminated, leaving absolute alcohol as a residue or final distillate.

Mixtures of alcohol and water have values intermediate between those of the pure components for some of their physical characteristics, such as viscosity, heat of vaporization, specific heat, thermal expansion, vapour pressure, electrical conductivity, boil-

ing point, refractive index and specific gravity. Although the variations may not be strictly proportional to the amount of alcohol present, they are nevertheless generally progressive for certain ranges, if not right through the scale of concentrations. This fact has provided some convenient physical means of determining spirit strength and it is common practice to derive such

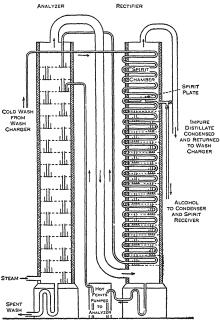

FIG. 7 .-- DIAGRAM OF COFFEY STILL

information from the specific gravity. Provided that the liquid is free, or has been freed by distillation, from saccharine and other matter which would interfere, the specific gravity is determined by immersing in it a hydrometer which may be graduated: (1) in terms of specific gravity; (2) with arbitrary scales (Great Britain, U.S.S.R.); (3) in percentages by volume of alcohol (Belgium, France, Italy, Norway, Spain, Sweden); (4) in percentages by weight of alcohol (Germany); (5) in percentages by volume of proof spirit (U.S.); (6) with a scale based upon fractions of the volume of the instrument (Netherlands). In all cases these instruments are calibrated at standard temperatures, and when the liquid to be tested is cooler or warmer (as it usually is), reference is made to tables to ascertain the true value for the spirit at the standard temperature.

Yet another way of ascertaining the specific gravity of the liquid is by the use of the pyknometer, or specific gravity bottle, which is calibrated by being weighed, filled with pure cold water, adjusted to standard temperature and weighed again. A similar procedure with the bottle filled with the spirit to be tested will provide a value which, when compared with the weight of water which can fill the bottle, indicates the specific gravity, and this in turn is found in appropriate tables to correspond with a spirit strength which is that of the solution under examination.

Spirit strength may be designated in several ways—percentage by weight, weight per gallon, gallons per hundredweight or percentage by volume, all these having reference to absolute alcohol and water. But there are other standards in common use; e.g., U.S. proof spirit, which is 50% by volume of alcohol and water, and British proof spirit, which is of such a strength that at 51° F. its weight is  $\frac{1}{8}$  of an equal volume of water; this solution contains 49.28% by weight or 57.10% by volume of alcohol at 60° F. The subject of alcohometry is comprehensively described in Simmonds' Alcohol. (See also ALCOHOL).

monds' Alcohol. (See also Alcohol.).

S. (1916).

SPIRITUALISM, a name used by some philosophers instead of idealism to signify a philosophic attitude or point of view about the universe opposed to materialistic philosophy and to imply that the ultimate reality is more fundamentally on the mental or ideal side of things rather than on that which appeals most directly to the senses as the behaviour and modifications of matter. But the name spiritualism or spiritism is more usually employed to signify a growing persuasion on the part of certain people that the activity of human beings is not entirely limited to the use they make of their bodily or material organisms on this planet. It is held that those organisms were constructed by an animating principle which having entered into relation with matter for the purpose of developing an individuality can continue long after the temporary material body is worn out or otherwise resolved into its elements; and, further, that the personalities thus brought into existence shall carry with them their memory, character, tastes and affection, which they had developed here while in association with matter, and shall be able under certain limitations to guide and influence terrestrial affairs in co-operation with those still living on the earth. This may be taken roughly as the spiritualistic interpretation or explanation of certain obscure phenomena which have occurred sporadically from time immemorial and which may be said to constitute the phenomena of spiritualism.

General Principles.—There is however a group of investigators who, while they accept the phenomena on the grounds of experience, are not prepared to accept the explanation in terms of human survival and who therefore dislike the term spiritualism, preferring to employ some noncommittal term such as metapsychics or parapsychology; meaning thereby a study of those obscure phenomena which lie outside the region generally accepted as orthodox psychology, and which suggest a possible extension of human faculty in directions not as yet understood. The object of these investigators is first to verify and then to study the facts oas to disentangle the laws which regulate them and seek to bring them within the recognized domain of organized human knowledge, or else to expand that domain so as to include them. This is called psychical research.

A third group of scientific men not only discard the spiritistic hypothesis but feel a doubt about the facts, regarding them rather as the outcome of savage superstition and folklore and therefore unworthy of scientific attention.

The whole subject therefore at the present time is a debatable one, on which there are many more or less legitimate differences of opinion. On the whole however there is a general consensus of agreement among those who have devoted time and attention to the subject that some of the phenomena are genuine; so that in time they must be accepted and gradually incorporated into the main body of science. They admit bowever that the investigation is conducted under difficulties, inasmuch as the phenomena cannot be produced at will, and because the facts are largely dependent on the good faith and careful testimony of those who experience them or who are allowed to witness them under sufficiently strict conditions. In so far as the phenomena appear to be dependent upon the activity of agents whose existence is not generally recognized, and who have the spontaneity and it may be the capriciousness characteristic of live creatures, the phenomena differ in many

er of the same

respects from the purely mechanical behaviour of atomic groupings and material bodies, such as form the customary stock in trade of astronomers, physicists and chemists. They appear likely to belong more to the domain of biology or even of anthropology when those sciences are sufficiently enlarged to include them. Meanwhile there is a great body of testimony as to their actual occurrences, which cannot properly be ignored.

But, again, this testimony depends on the utilization of people endowed with exceptional faculties, and these faculties are occasionally imitated by those who do not really possess them—a procedure which must be stigmatized in the strongest terms as fraudulent. There are others who, while possessing the faculties in a small degree, are tempted to enlarge and extend the results by normal supplement: a tendency which has to be constantly guarded against, for, if unchecked, it tends to bring the whole subject into disrepute.

Meanwhile, however, a body of careful investigators, notably those who founded in London the Society for Psychical Research, and others who have joined them or formed similar societies, have accumulated a great mass of evidence in favour of the phenomena, and the inquiry is still proceeding.

Assuming, on the strength of the evidence, that human faculties are not so limited as was at one time thought, and that these obscure phenomena actually occur, they may be classified into two great groups: (1) the mental, or purely psychical branch, concerned with the reception of ideas and information—information which could not have been normally acquired by the operator and therefore has to be styled supernormal; and (2) the physical branch, which concerns the production of effects in ordinary matter by apparently a supernormal extension of physiological processes.

To the first group belong such subjects as may be summarized under the heads telepathy, clairvoyance (qq.v.), lucidity, trance utterance, automatic writing, premonition, xenoglossy, psychometry and other apparent extensions of receptive faculty occasionally summarized under the rather question-begging term of cryptesthesia. It is chiefly on the strength of these mental phenomena that the hypothesis about the continued activity of the discarnate has grown up. For most of the communications so received purport to come, and certainly have the superficial appearance of coming, from intelligences no longer in the flesh who desire to send messages of condolence, sympathy and assurance to surviving relatives and to furnish proof of their continued activity. To this group must also probably be added the visual and auditory hallucinations (if that term can be properly used) which many people have experienced in the form of apparitions or other apparently sensory manifestations of the people concerned. It has been found that these appearances, or voices, are not limited to those of dead people, as they can be traced sometimes to the unconscious influence of living people when they are either asleep or in some danger or subject to some strong emotion. And these are called phantasms of the living.

The discovery of telepathy, that is to say the transference of thought or of ideas or emotions from one person to another without the use of any of the normal means of communication-a power which has been established by direct experiment as possessed by some people-tends to throw light upon these apparitions and indeed upon the whole spiritistic hypothesis. For if it is possible for one mind to influence another without the use of the material mechanism commonly employed, it tends to demonstrate an independence between mind and body which cannot fail to have important implications. Though neither the vocal cords nor any other muscles are used for transmission; although neither the eye nor the ear nor any of the other senses are used for reception; yet, since some brain process must at least indirectly be involved, it is just possible that telepathy may be caused by some unknown method of transmission between brain and brain. But no evidence has ever been adduced, at least none of any trustworthy character, for the existence of what have been called brain waves. And many circumstances connected with telepathy seem to render it unlikely that a physical method of transmission, even of an etheric kind, could be utilized for the

purpose of transmitting information, even though something analogous to brain waves existed. The great distance over which thought transference occurs and its apparent independence of obstacles are against such a hypothesis. For although the analogy of wireless telegraphy is often adduced, it must be remembered that we have no means of apprehending etheric waves except by the use of definite instruments: (1) for producing such waves in conscious and prearranged manner at one end; and (2) of detecting and transmuting them into sound or other mechanical movements at the other. Telepathy occurs without such instruments (assuming that it occurs at all), and nothing that has been detected in a screened organ like the brain makes it able to act as either a receiving or a transmitting instrument except through the agency of the nerves and muscles. Consequently the most natural hypothesis is that telepathy is a purely mental phenomenon, an action of mind on mind apart from the bodily organs; though the ultimate realization and demonstration of the occurrence must of course depend on the normal methods of testimony and record.

Now mental activity apart from the body is of the essence of the spiritistic hypothesis: and there would be no reason to object to the idea that deceased people can communicate information provided the great and fundamental step is taken of assuming that they still continue to exist. Conversely, the fact, so frequently testified to, that such communications are actually received, whether in the form of apparition or audition, or of automatic writing, or trance speech, or any other way, would, when established, also strongly support or even demonstrate the continued activity of the apparently operating personality. Hence it may be held that the discovery of telepathy rationalizes and renders more acceptable many of the asserted occurrences which otherwise would seem absurd and incredible. If an apparition were regarded as an objective reality all manner of difficulties would arise about the details. But if it is only a mental impression, perhaps roughly analogous to an image in a looking glass, although produced in some obscure and not in a simply optical manner, difficulties tend to disappear. The image can then be thought of as something not seen at all, but mentally reconstructed in accordance with a telepathic impulse which, indirectly through the mind, influences that part of the brain which is accustomed to receive an optical, or it may be an auditory, impression through the nerves. For, on any hypothesis, the brain and mind are closely interrelated; and a mental impression cannot be testified to or realized without the operation of the brain-nerve-muscle system.

## PHYSICAL PHENOMENA

On the spiritistic view—that is to say granted the working hypothesis that individuals once generated and isolated from a cosmic reservoir of life and mind, by means of their association with matter, shall continue to function as mental or psychic entities—it is fairly easy to suppose that they may be able to influence other minds, especially now that telepathy is fairly established as a vera causa, and can thus presumably cause inspiration and convey ideas or information. For it may reasonably be assumed that they have a wider outlook than when limited by the flesh; and, being also less restricted in time, that they may be in occasional touch with greater and higher intelligences on their side. Thus not only could ordinary lucidity and clairvoyance and even premonition be accounted for, but also the more valuable inspirations of genius.

It is not difficult to suppose that the organisms of people thus acted upon could be stimulated to produce such muscular movements as speaking and writing, or any other familiar bodily activity. The influence exerted on such people might still be considered purely mental and might be thought likely to operate most freely on the recipient organism when the medium or possessor of that organism is normally in a state of unconsciousness or partially suspended mental activity; but it would hardly be expected that the influence would be such as to produce physical phenomena beyond the capacity of the ordinary unstimulated organism. Nevertheless there is a large and growing body of evidence for the occurrence of even physically supernormal phenomena. Undoubtedly this svidence must be scrutinized with extreme care

because of its unusual character, so that the further question whether in some cases these phenomena are produced by the latent power of the normal individual, or whether they are dependent on a stimulus received from some other intelligence, may remain an open one, to be considered and classified later when the facts are thoroughly established.

The physical phenomena which have thus been seriously vouched for are such as the following. First, movement of objects without apparent contact, in other words, the displacement of matter at some distance from the boundary of the normal organism with no perceptible link and therefore out of the normal reach of the muscles. This is known as telekinesis or locomotion of objects at a distance. A modification of this phenomenon is the moulding or rearrangement of matter so as to produce an imitation of known objects, after the manner of a sculptor or a painter, so as to produce simulacra of hands and faces and other parts of the human organism out of any material available. Another fact which is testified to is the rearrangement of the particles on a photographic plate, so that when the plate is developed in the ordinary way a supernormal image of some kind appears upon it, whether it be writing or a human or animal figure. It is further asserted that if no suitable material is provided, or cannot be collected, some organized material can be drawn, either from the medium or from any of those present, of apparently a living or protoplasmic nature, remaining still associated or connected with the organism from which it is drawn; and that this externalized protoplasm is then independently manipulated so as to display a likeness of some departed person, more or less unsatisfactory and incomplete, but far beyond the normal power of the medium from which the material is drawn. Such exteriorized protoplasm is now generally known as ectoplasm. It only lasts a short time and has to be returned to the body whence it came. But meanwhile it is said that it can achieve many odd results, among others that it is able to produce direct voice, to move about and also to exert considerable muscular force, thus effecting the locomotion of objects already spoken of as telekinesis.

The testimony of investigators suggests the idea that this extraneous material is worked by an intelligent mind, much in the same fashion as our own bodily organisms are normally worked by our own minds, and that its activities show will and intention analogous to the will and intention of our own movements. We know too little about the relation between mind and matter to stigmatize such an hypothesis as intrinsically absurd: we must be guided by the facts. But the asserted facts are so extraordinary. and physiologically so incredible, that the evidence will have to be of a strong and cumulative character before such an idea can be accepted. Nevertheless it is mainly by physiologists well acquainted with the difficulties of such an hypothesis that it has been most responsibly put forward. And there is considerable testimony from some physiologists in Europe that, however odd they may be, phenomena which suggest this kind of activity are definitely found to occur. The ectoplasm appears to have varying consistency, sometimes being visible only, sometimes tangible only, sometimes neither and occasionally both. Ectoplasmic formations have been photographed, though it is said that they can sometimes only be photographed in ultra-violet light, and with the use of a quartz lens.

One special difficulty surrounding this investigation is that the ectoplasmic material seems to be manipulated or controlled through an etheric connecting link, and that a tremor or vibration in the ether, of the kind which normally excites the retina of the eye, is detrimental to its activity; so that in most ordinary cases operations of this kind have to be conducted, or seem to be easier, in the dark—a circumstance which makes investigation specially difficult and unsatisfactory. It seems to have been found however that red light is not so deleterious as the brighter illumination of higher frequency, and that with due preparation the ectoplasmic formations can be photographed by a flashlight before they are thereby disintegrated. Moreover it is asserted that in the case of some exceptionally strong mediums, some of the effects have been produced in full daylight.

The force exerted by the ectoplasm can be quite considerable.

For instance a table can be raised completely off the ground; and have been testified to by all nations and peoples, although they the weight of a man clambering on the table need not be sufficient to bring it down. The forces have sometimes been measured by spring balances: and an attempt has been made to weigh the medium from whom ectoplasm has hypothetically been removed, with the result that the normal organism is said to have lost weight corresponding to that of the material which has been extruded and accumulated on another balance.

In quoting such assertions it is not to be supposed that they are as yet fully accepted; but they indicate the lines on which investigation should proceed. The hypothesis gives a link on which the phenomena can be threaded together, so as to give them a sort of coherence, which further experience may either substantiate or

Still More Obscure Phenomena .- All the movements and mouldings hitherto spoken of are within the power of normal individuals, if they are allowed free use of their limbs. There is no difficulty in levitating objects or people, or in moulding images and simulacra. Hence the evidence for the occurrence of these things in a supernormal manner must depend on whether the medium and all those concerned are under complete control. Much of the experimentation is complicated by this necessity.

But there are certain other phenomena asserted which are not of a normal character and could not be produced normally if the operator were free-phenomena which might be spoken of as miracles. The one most commonly attested to is the immunity to damage or destruction by extreme heat. It is said that certain people can hold flaming or red-hot coals in their hands without feeling pain and without being singed; that this power can be conveyed to other people under certain conditions; and that even fabrics, such as hair or cambric, can be rendered temporarily immune to fire. Travellers tell us of native races who can walk through fire or over hot coals without injury when in a state of exaltation. Heat is known to be a rapid vibration or tremor among the particles of a body, and it is difficult to see how the molecular or chemical changes normally associated with such tremor can be suspended. But again, when there is sufficient confirmation, we must be prepared to accept the facts, whether we feel able to understand them or not.

Another phenomenon of what is popularly called a miraculous character, has been often asserted to occur, namely the passage of a solid body into or out of a closed cavity; as, for instance, the introduction of an object into a closed room, such object having been previously known to be outside; a phenomenon known as an apport. Verification of such a fact as that is singularly difficult. especially when the enclosure is, like a room, such as can readily be normally opened; and, like all the rest of the phenomena, it must depend with excessive cogency on the good faith of all concerned. Indeed good faith alone might not be sufficient. Before accepting a thing like that, one would have to allow for hypnotic or other influence.

A modification of this passage of matter through matter, as it has been called, is the linking of two entire rings together, or the tying of knots on an endless string. These things have been testified to but are hardly as yet even tentatively accepted. The disintegration and reconstitution of matter have been contemplated as a working hypothesis by the few who do accept them; while others have taken refuge in a fourth dimension of space, in which a globe is no more a complete enclosure than a circle is in three dimensions. A quadruped is fully confined when enclosed in a village pound, but a bird is not. The parable is obvious.

It is however hardly worth while to seek for some mode of conceiving or formulating an explanation until the facts are established. The object of this article has been, first, to show the kind of assertions which are made, and then to indicate the kind of lines on which a rational explanation may be looked for; at least in connection with those for which a prima facie case has been established; and, next, to suggest that an enlarged psychology, and possibly an enlarged physiology-possibly even an enlarged physics-will have to take into account and rationalize a number of phenomena which so far have been mainly disbelieved or ignored.

Historical Summary.-Although spiritualistic phenomena

are spread over the historical documents collected in the Old Testament and have continued down to the time of John Wesley and later, it is usual to attribute the rise of what is called modern spiritualism to occurrences which took place in the U.S. about the middle of the 19th century, when they began to attract rational attention; passing through a time of much scepticism and contumely until they have emerged in the moderate and cautiously sceptical atmosphere of today.

Examples of mediumistic and prophetical incidents are common from the time of the Hebrew patriarchs downwards. David and the other kings did not hesitate to consult seers, and, sometimes unwisely, regulated their conduct accordingly. The episode of the infant Samuel is a good example of the phenomenon called the direct voice. In the Graeco-Roman period monitions were experienced and oracles consulted as everyone knows. Coming down to recent times, the phenomenon, now fairly common, of intelligent raps, seems to have begun in a family at Hydesville near Rochester, N.Y., about 1848. Stainton Moses, himself a powerful medium, helped to establish the London Spiritualist alliance, which was joined by the naturalist Alfred Russel Wallace, while the physicist and chemist Sir William Crookes began a series of investigations into a variety of physical phenomena, with the help of the exceptional medium D. D. Home, through whom startling results had been obtained in good light, as narrated by Lord Dunraven (see "Experiences with D. D. Home" printed by Maclehose for the S.P.R.).

In the '70s of the 19th century Sir William Barrett made preliminary experiments in thought transference; and Cambridge men of letters began to study the various phenomena seriously. In 1882 a special society was founded by F. W. H. Myers and Edmund Gurney under the presidency of Henry Sidgwick. Society for Psychical Research accumulated a mass of information, critically examined, recorded and discussed in its Pro-

On the continent the subject was taken up by Charles Richet in France, Von Schrenck Notzing in Germany, Morselli, Lombroso and Schiapparelli in Italy, and carried on under Gustave Gelev and his successors in the Institut Metapsychique of Paris and other organizations; while the American Society for Psychical Research published an extensive collection of records. Charles Richet wrote what is virtually a textbook of the subject under the title Traité de Metapsychique, translated into English as Thirty Years of Psychical Research. And Geley discussed the subject from the medical, biological and philosophic points of view in From the Unconscious to the Conscious. Books containing what purport to be records of communications received through mediums in the trance state are too numerous to mention; but the eloquent work of F. W. H. Myers entitled Human Personality and its Survival of Bodily Death not only fairly covers the subiect up to 1900, but bids fair to become a classic. Selection from other books is difficult. A history of the subject in two volumes by Frank Podmore eschews the spiritistic hypothesis in order to emphasize telepathy. Another history of the subject emphasizing its religious bearings is by Arthur Conan Doyle. Older treatises are Hare's Experimental Investigations of the Spirit Manifestations (1856); Sophia De Morgan's From Matter to Spirit (1863); Alfred Russel Wallace's Miracles and Modern Spiritualism (1876); Stainton Moses' Spirit Teachings; Zöllner's work translated by Gerald Massey as Transcendental Physics. Also Reports of the Dialectical Society in London, and of the Seybert Commission in the U.S. and the Proceedings of the Society for Psychical Research.

Research.

Billiography.—Books aiming at a philosophical or biological discussion of the subject, in addition to those already mentioned, are: Eugène Osty, Supernormal Faculties in Man; Morton Prince, Discussion of Personality; William McDougall, Body and Mind (1920); Woldin Tischner, Mind and Personality (1927); Rudolf Tischner, Telepathy and Clairvoyance (1925); Gustave Geley, Ectoplasm and Clairvoyance; Traugott Ocsterreich, Occultism and Modern Science. The Pacts of Psychic Science and Philosophy by Campbell Holms is an uncritical summary of a large number of asserted observations. Books containing detailed evidence are such as the following: F. W. H. Myers and Edmund Gurney, Phaniasms of the Living, 2 vols.

(1886); C. L. Tweedale, Man's Survival after Death; Delanne, Evidence for a Future Life; Joire, Psychical and Supernormal Fennemens; Nicholas Flammarion, After Death, etc, 3 vols.; William Barrett, On the Threshold of the Unseen (1918); and many books by J. Arthur Hill, H. A Dallas, Drayton Thomas and others. (O J L)

SPITALFIELDS, a district of London, Eng., in the western part of the metropolitan borough of Stepney. The name is derived from the fact that the land belonged to the hospital or "spital" of St. Mary Without Bishopsgate, founded in 1197.

SPITHEAD, the name of an important anchorage in the strait known as the Solent which stretches between the Isle of Wight and the mainland of England. The name has often been incorrectly applied to the eastern half of that strait, but is properly restricted to the anchorage extending along the south side of the Spit Sand, which runs from Gillicker point to the Spit fort in an east-southeasterly direction, outside Portsmouth harbour which is the principal station of the British navy. As a result of this position and of the space available, Spithead has been the scene of many of the great pageants and gatherings of the British navy on the occasion of coronations, mobilizations and special occasions, a historic one being that of the funeral of Queen Victoria, who died in the Isle of Wight in 1901.

SPITSBERGEN (Norwegian SVALBARD), an arctic archipelago between Greenland and Novaya Zemlya in 76° 25′ to 85° C., has a total area of 23,979 sq.mi. 80° O'N. and 10° 20′ to 35° E., has a total area of 23,979 sq.mi. 80° documents West Spitsbergen (15,000 sq.mi.), North-East Land (about 6,000 sq.mi.), Edge Island (2,300 sq.mi.), Barents Island (580 sq.mi.), Prince Charles Foreland, the Wiche Islands, Hope Island and many smaller islands, including Bear Island in about 74° 30′ N., 10° E. Norway took possession officially in 1925. The population, largely miners, shifts seasonally: the 1930 census showed 600; the 1946 census, 1,057; and a 1949 estimate, 3,950.

There is no indigenous population.

Geography.—The chief island is in the main a much dissected plateau with many deep fjords penetrating far inland. Small plains are found in the north and west. The sharp peaks that gave Spitsbergen its name rise to 4,060 ft. in Horn Sund Tind in the south. 3,450 ft. in Mt. Monaco on Prince Charles Foreland and 4,770 ft. in Mt. Eidsvoll in the northwest. In the middle and east the mountains are flat-topped and seldom over 2,000 ft., but Mt. Newton (5,445 ft.) in New Friesland is the loftiest peak in Spitsbergen. Rocks skirt many stretches of the open coasts but with accurate charting a number of safe harbours have been found. Glaciers fill the valleys except in the southern interior where they have receded. They generally reach the sea, often along broad fronts, but give rise to no large icebergs. Many are in a state of decrepitude, but a few seem to be advancing. An ice covering over New Friesland is the nearest approach to an ice sheet in West Spitsbergen. Barents and Edge Islands have glaciers only on the east. The Wiche Islands have no large glaciers, but North-East Land and Giles (Gillis) Land are each covered with a dome of ice that almost envelopes the island. Prince Charles Foreland has numerous glaciers. Bear Island with an area of 73 sq.mi. rises to 1,630 ft. in Mt. Misery. The northern part is a plain at an elevation of about 150 ft. There are no glaciers. Harbours are small and poor. Hope Island lies 125 mi. east of South cape, Spitsbergen, is 20 mi. long and not more than 1 mi. wide. It rises to 1,200 ft. There is no harbour.

Structure and Geology.—The principal features of the geology are known. Most formations from early Palaeozoic, and perhaps Archaean, to recent, occur. The oldest rocks appear chiefly on the west and north, including Prince Charles Foreland and North-East Land. They are the Hecla Hook series of Cambrian and Ordovician dolomites, limestones, shales and quartaites which form the Caledonian folds and overthrusts of the west. The folds can be traced as far east as the west of North-East Land. Granite and gneiss formerly believed to be Archaean probably belong to the same formation and were involved in the Caledonian foldings. Some of these crystalline rocks, however, may prove to be pre-Cambrian. Outside the area of these old rocks Spitsbergen is mainly a plateau of relatively undisturbed strata lying unconformably on a platform of pre-

Devonian crystalline rocks. In the northwest there are Devonian rocks. These are unconformably overlain by Lower Carboniferous or Culm sandstones and shales with some coal. Middle Carboniferous is rare and the Culm is generally succeeded by Upper Carboniferous limestones, Permo-Carboniferous cherts and Permian sandstones and shales. Next come Triassic, Jurassic and Cretaceous sandstones, limestones and shales. In the Cretaceous beds there is coal. Unconformably there follow Tertiary sandstones and shales with several coal seams. Tertiary folding is obvious in the west against the Hecla Hook beds in places and in the east, but in central Spitsbergen is noticeable only in gentle undulations. Heavy faulting occurred in Tertiary times. Intrusions of dolerites and basalt were probably of Cretaceous (Neocomian) date. An extinct volcano and several hot springs (temp. 82° F.) in Bock bay are Quaternary. The strand flat is well developed at 30-60 ft. and postglacial raised beaches are marked. Glacial and postglacial debris on low ground generally mask the solid rock and loose screes form fans on the lower slopes. Bear Island is built of Hecla Hook, Devonian and Carboniferous beds. latter series contain some coal.

Climate and Ice Conditions.—The sea around Spitsbergen is shallow and the ice readily accumulates round the shores. Pack ice prevents access to most shores except for a few months in the year. However, the warm North Atlantic drift sends a branch to the western shores of Spitsbergen, moderating its climate and leaving an open passage which permits vessels to approach the western coast during most months of the year. The fjords are

frozen from October or November to April or May.

Owing to the warm drift the climate of Spitsbergen is less severe than in the corresponding latitudes of Greenland. January and February means range from  $\circ^\circ$  to  $-8^\circ$  F., and July means from  $38^\circ$  to  $40^\circ$  F. Even in the coldest months of the winter a thaw may set in for a few days, but on the other hand snow sometimes falls in July and August. Spring comes in June; the snow becomes saturated with water and disappears in places and scurvy grass and willow open their buds. By the end of June the thermometer has ceased to sink below the freezing point at night; July, August and September are the best months. In September, however, autumn sets in. The arctic night begins in October and lasts through February. The annual precipitation at Green harbour is 11.6 in. and less in the interior. Winds are generally light except on the west coast and local winds in the fjords. There is mist on the west and around Bear Island in summer.

Fauna.—The Greenland whale has disappeared in consequence of the great havoc made by the early whalers. According to William Scoresby, no fewer than 57,590 whales were killed between 1669 and 1775. Reckless extermination of seals also took place. Walruses are now rarely seen in the waters of West Spitsbergen. Birds, also, have rapidly diminished in numbers. fulmar petrel meets ships approaching Spitsbergen far away from the coasts. It makes colonies on the cliffs, as also do the glaucous gull or the "burgomaster." Rotches, black guillemots, ivory gulls, auks, looms and kittiwake gulls breed on the cliffs, while geese, loons and snipe frequent the lagoons and small fresh-water ponds. The eider duck breeds on the islands, but its numbers have become noticeably reduced. These birds, however, are only guests in Spitsbergen, the snowy owl and ptarmigan being the only species which stay permanently. About 60 species have been recorded from Spitsbergen and Bear Island; about half of them breed there. Of land mammals, besides the polar bear, the reindeer and arctic fox have been greatly reduced. Norway has rigorously restricted the slaughter of reindeer; before 1868 from 1,500 to 2,000 were killed by hunters in a few weeks of summer.

Vegetation.—The only trees are the polar willow, which does not exceed two inches in height, and the rare dwarf birch; and the only bushes are the crowberry and cloudberry. But at the foot of the bird cliffs some loam has been formed notwithstanding the slowness of putrefaction, and there, in contrast with the brownish lichens that cover the rocks, grows a carpet of mosses of the brightest green, variegated with the golden-yellow flowers of the ranunculus, the large-leaved scurvy grass, the cuckoo flower, many saxifrages, foxtail grass, etc.; while on the driest spots yellow

SPITTA 24.9

poppies, whitlow grasses and rock roses are found. Even on the higher slopes, 2,500 ft. or more above the sea, the poppy is occasionally met with. In all about 130 species of flowering plants have been found. The distribution is suggestive: most species are found in Europe and 117 are circumpolar; many of the plants common on the west coast are absent in the eastern part because

of the greater cold.

Mining.—Coal, known since the 17th century, was not mined commercially until the 20th century workings at Advent bay. Progress was slow until 1914, when war curtailed other sources of Scandinavian supplies. The Longyear mine at Advent bay. U.S.-owned after 1905, was sold in 1916 to a Norwegian group. Norwegian mines have also opened at King's bay, Hjorth Haven and other places. Swedish mines were worked from 1917 to 1925 in Lowe sound (Braganza bay); British mining revived after 1919 at Klaas Billen bay, Temple bay and Coles bay; and the Dutch operated mines at Green harbour. In 1948-49 exports totalled 424,323 tons, used in northern Norway and for the Russian arctic fleet. The product is good steam coal of Tertiary and Cretaceous ages: bituminous coal of Carboniferous age is also available but as yet unmined. Mining continues through the year, but shipping is from late April through September.

Communication.-Regular boat sailings are lacking, but contacts are maintained through tourist steamers and the frequent colliers of the summer. A Norwegian radio station was established at Green harbour in 1911, and later stations and post

offices were set up at the chief mines.

Exploration.- It is probable that Svalbard, discovered by the Vikings in 1104, according to the Landnamabok, was Spitsbergen, but the discovery was forgotten. Modern knowledge dates from the discovery by Willem Barents and Jacob Heemskerk, on June 17, 1596. Barents saw parts of the west and north coasts, and he gave the name of Spitsbergen. In 1607 H. Hudson, after visiting Greenland, reached Spitsbergen and reported whales. Bear Island, midway between Spitsbergen and the North cape, had been discovered by Barents, and became important as a hunting ground (for walrus, etc.) after Stephen Bennet's visit in 1603. In 1600 Thomas Marmaduke reached Spitsbergen, and in the following year the first hunting expedition was dispatched thither by the Muscovy company under Jonas Poole, whose report resulted in the start of the whaling industry there in 1611. The Dutch quickly came in, causing collisions between the whalers of the two nationalities, and in 1615 the Danes laid claim to "this part of Greenland," as it was then considered. The Russians called the region Grümant, a corruption of Greenland, and well before 1740 were hunting there for walrus, seal, bear, fox, etc. Marmaduke had discovered Hope Island and North-East Land in 1613; Edge saw the Wiche Islands in 1617; and C. Gillis found Gillis (Giles) Land

Many expeditions have made Spitsbergen their base for polar exploration. The expedition in the "Racehorse" and "Carcass" sent from England in 1773 under C. J. Phipps was the first having a purely geographical purpose. Phipps mapped the north of Spitsbergen and reached 80° 48' N. In 1818 D. Buchan and J. Franklin reached 80° 34' to the north of the archipelago. Capt. D. C. Clavering and Sir Edward Sabine in 1823 explored the islands, and Sabine made his remarkable magnetic observations, while Clavering reached 80° 20' N. Sir William Parry in 1827 reached 82° 40' N, of Spitsbergen on sledges. In the same year the Norwegian geologist, B. M. Keilhau, visited the group. The Swede, Sven Loven, was the first to undertake, in 1837, dredging in Spitsbergen waters. In 1858 Otto Torell, accompanied by A. E. Nordenskiöld and A. Ouennerstadt made important observations and brought home rich geological collections. In 1861 a larger expedition led by Torell, Nordenskiöld, A. J. Malmgren and K. Chydenius investigated the possibility of measuring an arc of meridian in Spitsbergen. The work of the measurement of the arc was completed in 1864 by an expedition led by Nordenskiöld, assisted by Malmgren and N. Dunér. In 1868 Nordenskiöld sailed to the north coast, and a German expedition under K. Koldewey circumnavigated West Spitsbergen. In 1870 two young Swedes, A. G. Nathorst and H. Wilander, examined the phosphoric deposits at

Cape Thordsen, and two years later a colony tried unsuccessfully to work the beds. Leigh Smith and the Norwegian Capt. E. Ulve visited and mapped parts of east Spitsbergen in 1871 and reached 81° 24' N. In the same year the first tourist steamer visited the archipelago. In 1872 and 1873 expeditions under Nordenskiöld explored North-East Land and crossed the vast ice sheet which covers it. In 1882 the Swedish geologists A. G. Nathorst and G. de Geer gathered in Ice fjord data about the geology and flora of the islands. Also in 1882 a Swedish meteorological station was established at Cape Thordsen for carrying on the observations desired by the international polar committee. Expeditions of Gustav Nordenskiöld in 1890 and the circumnavigation by Nathorst in 1898 explored the coasts of the Wiche Islands and Giles Land. In 1892 C. Rabot made the first serious attempt to penetrate the interior from the head of Ice fjord, exploring a part of the Sassendal; and in 1896 Sir Martin Conway led an expedition which crossed the island for the first time and surveyed the region between Ice fjord and Bell sound. In 1897 Conway and E. J. Garwood surveyed the glaciated area north of Ice fjord and climbed Horn Sund Tind. In the same year S. A. Andrée made his fatal balloon ascent from Danes Island with the intention of floating over the pole. In 1806 a weekly service of Norwegian tourist steamers was established in summer, with an inn at Advent bay. In 1898, 1899 and 1906 the prince of Monaco made scientific investigations in the archipelago, and in 1898-1902 Swedish and Russian expeditions undertook the measurement of an arc of the meridian. W. S. Bruce, in 1906-07-09, made a complete survey and scientific investigations of Prince Charles Foreland, and in 1920 J. M. Wordie scaled some of its highest peaks, Monaco. Rudmose and Barents. In 1910 W. Filchner surveyed the glaciated region between Temple and Mohn bays. King's bay was used by R. Amundsen in his unsuccessful flight to the pole in 1925, and by him and R. E. Byrd in their successful flights in 1926. G. Wilkins alighted in the fjord in April 1928 after his flight from Alaska. The Norwegian government began regular summer expeditions in 1906, in which G. Isachsen, A. Staxrud and A. Hoel surveyed and conducted hydrographic research. Joint Norwegian and Swedish expeditions took place in 1931 and 1934. in the latter of which H. W. Ahlmann studied glaciology while H. U. Sverdrup studied the problems of heat, water vapour and momentum in the melting of the snow. In 1936 the Norwegians mapped about two-thirds of the group by aerial photography. (See also Arctic Regions: Exploration.)

Political History.-Despite diverse interests in and claims to the islands by British, Dutch, Norwegians, Swedes, Danes, Russians and even Americans, the question of sovereignty was long unsolved, and Spitsbergen was a terra nullius. Norway initiated a conference on the matter in Christiania (Oslo) in 1910, which was followed by others in 1912 and 1914, all without result. In 1919 Frits Wedel-Jarlsberg persuaded the Allied supreme council to grant to Norway sovereignty over Spitsbergen, Bear Island and all the lands lying between 74° and 81° N. and between 10° and 35° E. The act was validated by a treaty of Feb. 9, 1920, signed by Great Britain and the British dominions, the United States, France, Italy, Japan, Holland, Denmark, Norway and Sweden; soviet Russia adhered later. Norway took formal possession on Aug. 14, 1925. Norway then declared the region a part of the kingdom of Norway and appointed a governor (sysselmann).

In Aug.-Sept. 1941, a force of Canadians, British and "Free Norwegians" made a sudden landing, destroyed the radio stations, chief mines, about 450,000 tons of mined coal and 275,000 gal. of oil. The Norwegian population was evacuated to England, and about 2,000 Russian miners were transported to a north Russian port. The Allies established a base which was attacked by the Germans in Sept. 1943. (R. N. R.-B.; F. D. S.)

SPITTA, FRIEDRICH (1852-1924), German Protestant theologian, was born at Wittingen Jan. 10, 1852. He studied at Göttingen and Erlangen and in 1887 became professor ordinarius and university preacher at Strasbourg. In 1896 he began to edit, with J. Smend, the Monatschrift für Gottesdienst und Kirchliche Kunst. From 1919 until his death he taught at Göttingen, where he died June 8, 1924.

SPITTA, JULIUS AUGUST PHILLIP (1841–1894), German writer on music, was born at Wechold, Hanover, our Dec. 27, 1841. He studied philology at Göttingen and held seweral teaching posts before going to Leipzig, where he helped to found the Bachverein in 1874. A notable teacher, in 1875 he became professor of musical history at the university of Bellin and at the Hochschule für Musik, of which he became director in 1882. His J. S. Bach is one of the great classic musical biographies. Spitta was associate editor of the Vierteijahrsschrift für Musikusisenschaft from 1885 and played a leading part in publishing Denkmaler Deutscher Tonkunst. His other works include an important critical edition of the organ works of Dietrich Buxtehude and an edition of the complete works of Heinrich Schitz.

SPITTELER, CARL (1845-1924), Swiss poet and novelist, was born at Liestal, near Basle, April 24, 1845, and died at Lucerne Dec. 28, 1924. In youth he studied theology but he did not pursue a clerical career. After many years of teaching (eight of them in Russia), he published his first important work, Prometheus and Epimetheus, in 1880-81, under the pseudonym of "Felix Tandem." This was an epic, written in a rhythmical, quasi-biblical, hieratic prose. A little later appeared Extramundana (1883), a volume of apologues in verse. From 1885 to 1892 he engaged in journalism, but published Schmetterlinge (1889), a series of short poems. After 1892, when he settled in Lucerne, he was able to devote himself wholly to literature. Three other volumes of short poems were produced between 1892 and 1906-Literarische Gleichnisse, Balladen and Glockenlieder. In 1900-05 appeared his long epic, Olympischer Frühling, which was cited as the main ground for the award of the Nobel prize for literature in 1919. His prose writings include Imago (1906) and three other romances; Lachende Wahrheiten, a volume of essays (1898; Eng. trans. 1927); Die Mädchenfeinde (1907; Eng. trans., 1922), a story founded on a reminiscence of his boyhood; and Meine frühesten Erlebnisse (1914), a charming account of his childhood. His last work, published in 1924, shortly before his death, was Prometheus der Dulder, a metrical, compacter and maturer treatment of the theme of Prometheus and Epimetheus.

BIBLIOGRAPHY—See short lives and studies by Felix Weingartner (1904), Carl Meissner (1912), O. Kluth (1918, in French) and Rudolf Cottschalk (1928). The most complete English notices of him are in Studies of Ten Literatures by Ernest Boyd (1923) and in an article by J. G. Robertson in the Contemporary Review (Jan. 1921). SPIX, JOHANN BAPTIST VON (1781–1826), German naturalist, was born in Hochstadt, Bavaria, Feb. 9, 1781. For a time he was curator of the Munich Zoological museum but in 1817 he left to accompany Karl Friedrich Philipp von Martius, Bavarian naturalist, to Brazil, a mission on which they were sent by the Bavarian government. They remained in Brazil until 1820, Martius studying its flora and Spix its fauna. On their return they collaborated on Reise in Brasilien, a three-volume work on the country's natural history. He died in Munich, March 13, 1826.

SPLEEN is a vascular type of organ without a duct and has been called a ductless gland. It is located in the upper left quadrant of the abdomen just below the diaphragm. It is soft and cannot be felt on abdominal examination when normal in size, consistency and position. It has important functions to perform in relation to the physiology and pathology of the blood. The functions are not fully understood. This organ often enlarges in diseases such as typhoid fever and malaria. It may be greatly enlarged in certain types of disease of the blood-forming organs, such as leukemia. It was thought at one time to have something to do with emotional reaction, which gave rise to such a phrase as "vent his soleen."

(See Blood.) (F. L. A.)

SPLIT or SPLJET, a city of Croatia, Yugoslavia (Ital. Spalato), has the finest harbour on the Adriatic coast, with a broad bay affording deep, sate anchorage. This, combined with its cental position, and good communication with other parts by road, rail and steamer, made it of great commercial importance, with an extensive trade in cement and marl. Pop. (1948) 49,885, almost entirely Serbo-Croatian. Spalato arose from the palace of Diocletian, who renounced the imperial crown in A.D. 303 and

lived here until his death. The palace was then allowed to fall into ruin, but when the incursion of the Avars was over (620) the inhabitants of the ruined city of Salona, near by, took refuge here, and built up homes within the nine and one-half acres covered by the palace, incorporating its walls and pillars. Its ground plan is like a Roman camp; i.e., almost a square with four quadrangular towers and four gates, with four streets meeting in the middle. The eastern gate or Porta Aenea is destroyed, but the western gate or Porta Ferrea and the main entrance to the building, the beautiful Porta Aurea, are still in fairly good preservation. The streets are lined with massive arcades. The vestibule now forms the Piazza del Duome or cathedral square; to the northeast of this lies the temple of Jupiter, or perhaps the mausoleum. Since the oth century this has been the cathedral of St. Doimo or Domnius, noteworthy for its finely carved choir stalls. To the southeast is the temple of Aesculapius, long transformed into a baptistery, a beautiful Romanesque campanile having been added in the 14th and 15th centuries.

Excavations have been carried on intermittently at the ruins of Salona, four miles northeast, since 1818, and many interesting architectural remains have been discovered together with many smaller relics, now housed in the Split museum. These include prehistoric objects. Salona was made a Roman colony in 78 B.C. and was one of the chief ports of the Adriatic. Soon after 313 the city became an episcopal see with St. Doimo as its first bishop. The palace was transformed into an imperial cloth factory. The town was captured several times by the Goths and Huns and in 630 was destroyed by the Avars, but was not entirely deserted until the end of the 12th century. In 659 John of Ravenna, the papal legate, was created bishop of Spalato, as the new city was called, the origin of the name being uncertain. A little later it became an archbishopric and its holders were metropolitans of all Dalmatia until 1033. In 1105 Spalato became a vassal state of Hungary; in 1327 it revolted to Venice, but in 1367 returned to Hungary. It was ruled by the Bosnian king, Tvrtko, from 1390 to 1391, and in 1402 by the famous Bosnian prince, Hrvoje. A large octagonal tower is still known as Torre d'Harvoye. In 1420 Spalato fell to Venice and ceased to have an independent history. The castle and walls were erected by the Venetians between 1645 and 1670 and dismantled during the French occupation of Dalmatia (1805-13) in which latter year the province came under Austrian rule and remained there until 1918. In that year Italy occupied the town for a short time, but from 1919 to 1941 the town was Yugoslav. In 1941 it was again occupied by Italians.

town was Yugoslav. In 1941 it was again occupied by Italians. Ser T. G. Jackson, Dalmatia, the Quarnero and Istria (Oxford, 1887); E. A. Freeman, Subject and Neighbour Lands of Venice (London, 1881); R. Munro, Bosnia, Hercegovina and Dalmatia (London, 1900); for researches at Salona, R. Adams, Ruins of the Palace of the Emperor Diocletian at Spalato, in Dalmatia (London, 1764) with engravings by Bartolozzi; L. J. Cassas and J. Lavallee, Voyage pittoresque et Historique de l'Istrie (Paris, 1802) illustrated; and G. Lucio, De Regno Dalmatiae et Croatiae (Amsterdam, 1666) for chronicles relating to Spalato and Salona.

SPLÜGEN PASS, one of the passes across the main chain of the Alps from Switzerland to Italy. The route from Thusis passes first through the celebrated gorge of the Via Mala, then through the Schams basin and past Andeer, beyond which the Rofna gorge gives access to the village of Splügen in the upper reach of the main or Hinter branch of the Rhine (q.v.). Leaving to the west the road over the San Bernardino pass, 6,769 ft., the Splügen road (constructed in 1823) mounts south to the pass (6,946 ft.) which forms the political frontier. On the other side the road avoids the old path through the dreaded Cardinello gorge (here passed Alexandre Macdonald's army in Dec. 1800) in order to descend by zigzags to Pianazzo. Thence past Campo Dolcino and Gallivaggio the descent is made to the ancient town of Chiavenna at the junction of the road from the upper Engadine over the Maloja pass, and 17 mi. by rail above Colico, at the northern end of the lake of Como.

**SPODUMENE**, a lithium-aluminum silicate (LiAl[SiO<sub>8</sub>]<sub>2</sub>) belonging to the pyroxene group (see Pyroxene), named in 1800 from Gr.  $\sigma\pi\delta\delta\omega$ s (ash-coloured), in allusion to its colour, and soon afterwards termed by J. R. Haiy triphane  $(\tau\rho\iota\phi\alpha\nu\dot{\eta}_5, appearing threefold)$  because it exhibited certain characteristics

equally in three directions. Spodumene crystallizes in the monoclinic system, the crystals having generally a prismatic habit and being often striated longitudinally. It has perfect prismatic cleavage and imperfect cleavage parallel to the clinopinacoid, while a lamellar structure may be developed by parting along the orthopinacoid. The hardness is 6.5 to 7, and the specific gravity about 3.16. Though generally a dull mineral, some varieties of spodumene are so brightly coloured and transparent as to be valued as gemstones; e.g., the emerald-green hiddenite and the lilac-coloured kunzite, while a yellow or yellowish-green spodumene found as pebbles in the state of Minas Gerais, Brazil, resembles, when cut, some kinds of chrysobeyl.

Common spodumene is used as a source of lithium in chemical preparations.

Spodumene occurs in granite and crystalline schists. The original specimens came from the isle of UG. Swed, but the finest examples are found in the United States, especially in Massachusetts, fine specimens having also been obtained from the Black Hills of South Dakota. Some remarkable deposits containing spodumene were discovered many years ago at Branchville, Conn, and were exhaustively studied by G. J. Brush and E. S. Dana. The spodumene occurred in large quantity, in a vein of albitegranite, associated with apatite, garnet, columbite, pitchblende and other uranium minerals, with several manganese phosphates.

SPOFFORTH, FREDERICK ROBERT, (1853–1926), Australian cricketer, was born at Sydney, N.S.W., on Sept. 9, 1853, and died at Surbiton, Sur., on June 4, 1926. He was educated at Eglington college, Sydney, and played in Australia up till 1888, when he came to England, and played occasionally in England until 1896. He visited England in the five tours from 1878 to 1886, and in his two great years, 1882 and 1884, took 188 and 218 wickets.

SPOHR, LUDWIG (1784–1859), German composer and violinist, was born at Brunswick on April 24, 1784. He spent his childhood at Seesen, where in 1789 he began to study the violin, and at six years old was able to take part in chamber music. He learned a great deal from studying the scores of Mozart, and later became a student of Franz Eck.

His first violin concerto was printed in 1803, and in 1805 he became violinist to the duke of Gotha. Spohr failed to have his first two operas (Die Prijung and Alruna) produced, but his third, Der Zweikampt mit der Geliebten, was successfully performed in Hamburg in 1810, a year after it was written. In 1811 he produced his (first) Symphony in E flat, and in 1812 composed his first oratorio, Das jüngste Gericht. In that year he also became leader of the orchestra at the Theatre an der Wien, Vienna, and began his faramatic masterpiece, Faust, which he completed in 1813. He resigned his post at Vienna in 1815 and toured Italy, returning to Germany to become conductor of the opera at Frankfurt (1817) and later Kapellmeister at Cassel (1822).

In 1822 Mendelssohn, then a boy of 13, visited Cassel; a friendship sprang up between the two, which ceased only with Mendelssohn's death in 1847. Spohr's next three operas, Der Berggeist (1825), Pietro von Abano (1827) and Der Alchymist (1830), attained only temporary success. At the Rhenish musical festival held at Düsseldorf in 1826, his oratorio Die letzten Dinge (The Last Judgment), the most famous of his sacred compositions, was produced. In 1831 Spohr published his Violin School. The year 1834 was saddened by the death of his first wife, Dorette Scheidler, a celebrated harpist. Two years later he married a pianist, Marianne Pfeiffer. During 1833 he worked on an oratorio-Des Heilands letzte Stunden (Calvary or The Crucifixion), which was performed at Cassel on Good Friday 1835, and sung in English at the Norwich festival of 1839 with an effect which he later referred to as the greatest triumph of his life. For the Norwich festival of 1842 he composed The Fall of Babylon, which was also a success, though the elector of Hesse-Cassel refused Spohr leave of absence to conduct it. His last opera, Die Kreuzfahrer, was produced at Cassel in 1845. Of his nine symphonies the finest, Die Weihe der Tone, was produced in 1832.

Spohr's compositions for the violin include concertos, quartets, duets and other concerted pieces and solos, and among these a high place is taken by four double quartets; i.e., octets for two antiphonal string-quartet groups, an art form of his own invention. He died in Cassel on Oct. 16, 1859.

SPOIL FIVE, once known as the national card game of Ireland, akin to the British napoleon, the American euchre and the French écarté. Not only spoil five but its variant forty-five were carried to the United States and Canada, while the variant auction forty-fives, introduced into Newfoundland in 1912, became the principal club game there.

The pack of 52 cards is used in spoil five. Any number from two to ten may play, but four, five or six make the best game. The ace of hearts is always third-best trump, and the rank of the cards is unique:

As trumps, spades and clubs rank 5 (high), J (knave),  $\nabla$  A, A, K, Q, 2, 3, 4, 6, 7, 8, 9, 10; hearts rank 5 (high), J, A, K, Q, 10, 9, 8, 7, 6, 4, 3, 2; diamonds rank 5 (high), J,  $\nabla$  A, A, K, Q, 10, 9, 8, 7, 6, 4, 3, 2.

When not trumps, spades and clubs rank K (high), Q, J, A, 2, 3, 4, 5, 6, 7, 8, 9, 10; hearts rank K (high), Q, J, 10, 9, 8, 7, 6, 5, 4, 3, 2; diamonds rank K (high), Q, J, 10, 9, 8, 7, 6, 5, 4, 3, 2, A.

Each player puts an equal number of counters in the pool. Five cards are dealt to each player in rounds of three and two, or two and three, at a time. The next card is turned for trump; if it is an ace, the dealer may discard any card and take the ace (or may refuse to do so). If the turned-up card is not an ace, the player holding the ace of trumps may exchange any card for it or may refuse to do so.

Éldest hand leads, and each player in turn must either follow suit or play a trump if he is able to follow suit. When a lower trump is led, the holder of the five or knave of trumps or the heart ace may renege (refuse to follow suit) if he wishes. A trick containing a trump is won by the highest trump it contains, and any other trick by the highest card of the suit led. The winner of each trick leads next. A player who has won three tricks must abandon his hand and take the pool; or jink it (play on to win all five tricks and receive the pool plus an extra chip from each other player). If he jinks it and loses a trick, he does not get the pool. A pool not won in one deal is added to the next pool.

Forty-five is a variant in which there is no pool; four or six play, in partnerships of two or three to a side respectively. A side winning three tricks scores five points; all five tricks, ten points. As some play, winning four tricks scores 15 points and all five tricks 25 points. The first side to reach 45 points wins.

SPOILS SYSTEM. The practice in the United States under which the political party winning an election rewards its campaign workers and other active supporters by appointment to public office. It involves political activity by public employees in support of their party and the consequence of removal from office if their party loses the election. A change in party control of government necessarily brings new officials to those high positions carrying political responsibility, but the spoils system extends personnel turnover to varying proportions of routine or subordinate governmental positions. In the most extreme form of the spoils system the primary test for appointment is excellence of party service, with almost complete disregard of capacity to perform the duties of the public office concerned.

The term spoils system is often applied to the great variety of means by which money may be transferred move or less indirectly from the public treasury to the party coffers, as well as to other abuses of governmental power for partisan advantage. So used, the term includes abuses in the management of public expenditures, irregularities in the granting of franchises and like privileges, partisan favouritism in the administration of criminal law, discrimination in the levy of taxes and other corrupt uses of public power. The term will be limited here to its earlier and narrower usage.

Although patronage existed in colonial times, the spoils system came to full bloom in the period 1800-29. When Jefferson became president in 1801, he found the public offices filled with persons generally hostile to him and to his party. Without espousing the principle of rotation in office, he replaced enough Fed-

eralists with Republicans to assure a more even distribution between the two parties of posts in the civil service. Yet in both appointments and removals partisan considerations were not the sole criterion; it remained for President Jackson to adopt the principle of the spoils system in the national government. Spoils practices were instituted earlier in the governments of states and cities. The system first became firmly rooted in New York; it was established almost as soon in Pennsylvania. By 1828 in all the states of the north and west the system existed or strong groups desired to introduce it.

In his annual message in 1829 Jackson presented a reasoned philosophy of the spoils system. "There are," he said, "perhaps few men who can for any great length of time enjoy office without being more or less under the influence of feelings unfavourable to the faithful discharge of their public duties. Their integritmay be proof against improper considerations immediately addressed to themselves, but they are apt to acquire a habit of looking with indifference upon the public interests and of toleration in office, then, was not an evil but a positive good. "The duties of all public offices are," he declared, "or at least admit of being made, so plain and simple that men of intelligence may readily qualify themselves for their performance; and I cannot but believe that more is lost by the long continuance of men in office than is generally to be gained by their experience."

The common explanation of the rise of the spoils system is that ways had to be found to support the activities of political parties. With the broadening of the suffrage, the use of elections to choose large numbers of officials and other tendencies toward democratization, political parties had to assume heavy burdens in the conduct of campaigns and leadership of debate on public issues. No class existed with the time or inclination to assume these responsibilities and parties had to be maintained by patronage. Practical considerations of party finance were re-enforced by a democratic dislike of the idea of public office as private property and a hostility toward the rise of an officeholding class,

The spoils system is often said to be peculiar to the United States, but similar practices have existed elsewhere from time to time. In fact, the distribution of public offices to strengthen a regime is an ancient practice of statecraft. At the time of the founding of the United States government, the tests for appointment to the civil service were probity, ability and loyalty to the constitution. The test of loyalty aided in buttressing a new government emerging from controversy. The installation of fascist dictatorships in Germany and Italy was accompanied by considerable partisan dilution of the permanent civil service. If the nature of a government changes radically, a degree of turnover in the civil service is likely to occur. The introduction of the spoils system into the national government of the United States coincided with a veritable revolution as new classes came to power in national affairs. Even systems for the selection of public employees on the basis of merit may reserve by effect the higher positions for members of the dominant groups within the com-

The spoils system flourished unchallenged in the United States until after the Civil War. Bills to reform the civil service were introduced in congress in the 1860s but they attracted little attention and less support. In 1871 congress empowered the president to prescribe regulations to govern the selection of civil servants and to employ persons to aid him in determining the fitness of applicants. President Grant appointed a civil service commission, but it was dissolved in 1873 after congress had failed in 1873 and 1874 to provide funds for its support.

The National Civil Service Reform league, established in 1881, led a reform movement which succeeded gradually in restricting the spoils system by the introduction of the merit system for the selection of civil servants. The movement gained impetus from the assassmation of President Garfield by a disappointed office seeker and in 1883, the Pendleton act, largely drafted by leaders of the Reform league, was adopted by congress. It provided for the creation of the United States Civil Service commission and for the merit system in the recruitment of some fed-

eral civil servants. In the same year the New York legislature adopted a civil service law—that is, in American usage, a law requiring the selection of civil employees through competitive examination. Massachusetts followed in the next year.

The merit idea spread slowly but steadily. After 1939, all states were compelled to institute merit systems for those of their employees engaged in security programs aided by federal subsidies

The exact extent of the merit system in municipalities was difficult to ascertain, but by the 1950s about 75% of the U.S. cities had established some type of formal merit system, according to The Municipal Year Book (1953). However, only 25% of the cities covered all employees, and almost half of those reporting cities with a population of less than 25,000 had established no formal civil service system. As the merit system encroached on the spoils system in state and local governments, its application was broadened in the national government by actions of various presidents. A major setback to the principle of merit occurred after World Wars I and II in the extension to veterans of preference in appointments.

The coverage of civil service legislation, however, does not indicate accurately the extent to which the spoils system has been superseded. In jurisdictions with civil service laws, spoils practices may prevail. In those lacking formal merit systems, ability may govern selection of employees and their tenure may be permanent. Nevertheless, great progress was made toward the elimination of the spoils system. (See CIVIL SERVICE.)

(V. O. K.; X.)

SPOKANE, a city of eastern Washington, U.S., at the falls of the Spokane river, 50 mi. from its mouth in the Columbia river; a port of entry and the county seat of Spokane county. It is on federal highways 2, 10, 95, 195 and 395, and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Great Northern, the Northern Pacific, the Spokane International, the Spokane, Portland and Seattle and the Union Pacific railways, by Northwest and United air lines and by numerous motor-coach lines. Pop. (1950) 161,721; (1940) 122,001 (85% native white).

Spokane is the metropolis of the "Inland empire" of 100,000 sq.mi., lying between the Rocky mountains on the east and the Cascade or Coast range on the west and embracing eastern Washington, northeastern Oregon, northern Idaho, western Montana

and eastern British Columbia.

The city has an area of 41.4 sq.mi. and an altitude of 1,898 ft. It is surrounded by pine-clad mountains, rivers, cascades, waterfalls, lakes, orchards and fertile fields of grain. It is protected by the mountain ranges from extremes of heat and cold and from the fogs of the coast. The average year has 208 days of sunshine, 16.6 in. of rainfall and a growing season of 183 days between killing frosts. Through the city, in the heart of the business section, flows the Spokane river, tumbling over cataracts. The city is clean and well built, with substantial business buildings and commodious hotels, well-paved, well-lighted and well-kept streets and delightful views in every direction. In 1911 it adopted a commission form of government.

The park system includes about 3,000 ac.

A short distance to the west of Spokane, in central Washington, is the basin of the Columbia, containing a hydroelectric power development, Grand Coulee dam, and a great reclamation project. Spokane is the main gateway and an important supply centre for this development.

Military installations at Spokane include the U.S. air force base (heavy bomber), the U.S. naval supply depot and a \$5,000,coo veterans' hospital. Other important air, naval and ground reserve components occupy portions of Geiger and Felts fields.

Spokane is the home of Gonzaga university (Roman Catholic), Whitworth college (Presbyterian) and Holy Names college (Catholic). About 35 mi. from the city's centre is Mount Spokane State park, with the peak rising to 5,881 ft. Riverside State park, just outside the Spokane city limits, borders the shores of the Spokane river.

Spokane is important in the field of light metals, with a reduction plant and a giant aluminum rolling mill. There are 12

hydroelectric plants in the district (not including Coulee) with an installed capacity of 266,050 h.p., of which 183,000 h.p. represents the developed capacity of seven plants on the Spokane river in and This electric power operates mines, maintains exnear the city tensive irrigation projects, runs transcontinental trains and supplies current for industrial plants and street and domestic lighting.

History.-The first permanent settlement on the site of Snokane was made in 1874 by James N. Glover, who bought a tract of land from two trappers. The town was incorporated in 1881 as Spokane Falls, received a city charter later in the year and became the county seat in 1882. In 1890 "Falls" was dropped from the name.

an Indian tribe of Salishan stock which had formerly occupied the river valley.

The Northern Pacific railroad reached the city in 1883, the Union Pacific in 1889 and the Great Northern in 1892. On Aug. 4-6, 1889, a fire destroyed 30 blocks in the heart of the city, practically the entire business section, at a loss estimated at \$5,000,000, but within two years the district was rebuilt, with great improvements. The population was 19,922 in 1890, 36,848 in 1900 and 104,402 in 1910.

The pioneer who laid out the town site lived to see a city of more than 100,000.

SPOLETO (anc. Spoletium), a town and archiepiscopal see of the province of Perugia, Italy, 18 mi. N.N.E. of Terni, and 88 mi. N. by E. of Rome by rail. Pop. (1936) 10,579 (town); 32,341 (commune). It is situated on a hill, so that the lowest part is about 1,000, the highest 1,485 ft. above sea level, at the south end of the open valley of the Topino, a tributary of the Tiber, which it joins near Assisi. The principal industries are the collection and preparation of truffles and preserved foods, also tanning and the manufacture of earthenware, cotton and wool spinning. Spoleto is also the centre of an agricultural district, and contains a government experimental olive oil factory. There are few towns of Italy which possess so many Roman remains in good preservation under the mediaeval buildings, and few mediaeval towns with so picturesque an appearance. There are considerable remains of pre-Roman polygonal walls. There are remains of a Roman theatre, over 370 ft. in diameter, and an amphitheatre 390 by 295 ft. A Roman bridge of three arches, 80 ft. long and 26 ft. high, exists at the lower (north) entrance to the town.

The rock above the town was included within the polygonal walls: but Totila fortified, not this rock, but the amphitheatre, which remained the citadel until 1364, when Cardinal Albornoz destroyed it and erected the present Rocca, which was enlarged by Pope Nicholas V; it is now a prison. The Porta Fuga (the name alludes to the repulse of Hannibal) occupies the site of a Roman gate, but is itself mediaeval: while the mediaeval enceinte encloses a somewhat wider area than the ancient. The Piazza del Mercato represents the Roman forum; close by is a triumphal arch of Drusus and Germanicus (A.D. 21), and a temple (?) over which is built the church of S. Ansano. A Roman house in the upper part of the town, with mosaic pavements, probably belonged to Vespasia Polla, the mother of the emperor Vespasian. The Palazzo Municipale, above it, contains the archives and picture gallery. The cathedral of S. Maria Assunta, much modernized in 1634 by Bernini, occupies the site of a church of the Lombard dukes erected about 602. The present church was consecrated in 1198; the façade with eight rose windows belongs to the middle of the 12th century. Over the main entrance is a large mosaic of Christ enthroned, with the Virgin and St. John. by the artist Solsernus (1207). The Early Renaissance vestibule (after 1491) is fine. In the choir and on the half dome of the apse are the finest frescoes of Fra Filippo Lippi (scenes from the life of the Virgin) completed after his death by Fra Diamante: his tomb, erected by Lorenzo de' Medici, with the epitaph by Politian, is on the left of the choir. The fine stalls and panelling in the winter choir date from 1548-54. The Campanile is beautiful.

The church of S. Pietro, outside the town, has a façade richly sculptured with grotesque figures and beasts, of two different dates, about 1000 and about 1200. The little church of SS.

Giovanni e Paolo (12th century) contains frescoes of the 12th-14th centuries notably an early representation of the martyrdom of S. Thomas à Becket and a portrait of S. Francis of Assisi. S. Domenico is a fine example of later Italian Gothic with bands of different coloured stone. Both the church and its crypt contain 14th century frescoes. The triple-apsed crypt of S. Gregorio probably dates from the 9th century; the upper church was consecrated in 1146 and the Romanesque work covered with stucco in the restoration of 1744. S. Nicolò is a beautiful example of Pointed Gothic. The basilica of S. Salvatore (il Crocefisso) at the cemetery belongs to the 4th century A.D. The fine sculptures of the facade, with its beautiful windows, as also the octagonal dome, Spokan (said to mean "children of the sun") was the name of all belong to this period. It was restored in 1815. S. Ponziano, not far off, belongs to the 13th century. The city is still supplied with water by an aqueduct, to which belongs the huge bridge called the Ponte delle Torri, crossing the ravine which divides the town from the Monte Luco (2,723 ft.). The bridge is 253 ft. high and 755 ft. long and has ten arches: it was erected in 1364.

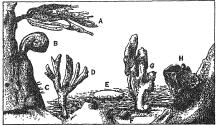

After the battle of Trasimenus (217 B.C.) Spoletium was attacked by Hannibal, who was repulsed. It suffered greatly during the civil wars. Sulla, after his victory over Crassus, confiscated the territory of Spoletium (82 B.C.). Under the empire it again became a flourishing town. It was situated on a branch of the Via Flaminia, which left the main road at Narnia and rejoined it at Forum Flaminii. An ancient road also ran hence to Nursia. Martial speaks of its wine. Aemilianus, who had been proclaimed emperor by his soldiers in Moesia, was slain by them here on his way to Rome (A.D. 253), after a reign of three or four months. The foundation of the episcopal see dates from the 4th century. Owing to its elevated position it was an important stronghold during the Vandal and Gothic wars. It was beautified by Theodoric (493) and fortified by Belisarius (536) but its walls were dismantled by Totila (546). Under the Lombards Spoleto became the capital of an independent duchy (from 570), and its dukes ruled a considerable part of central Italy. Together with other fiefs, it was bequeathed to Pope Gregory VII by the empress Matilda, but for some time struggled to maintain its independence. In 1155 it was destroyed by Frederick Barbarossa. In 1213 it was definitely occupied by Gregory IX. During the absence of the papal court in Avignon it was a prey to the struggles between Guelphs and Ghibellines, until in 1354 Cardinal Albornoz brought it once more under the authority of the Church. In 1809 it became capital of the French department of Trasimene. In 1860 it was taken by the Italian troops after a gallant defense.

At Monteleone di Spoleto a circular tumulus was found in 1902, with a rectangular chamber in the centre, and in it was the famous biga (two horse chariot), the only ancient one found in a complete state, which is now in the Metropolitan Museum at New Vork (T. A.)

SPONGES, or Porifera (from Latin porus, pore, and fero, to bear), are the simplest animals of the subkingdom Metazoa, which comprises all the multicellular forms. The body of a sponge consists of a rather loose aggregation of cells supported by a framework of spicules or fibres which form intricate skeletal structure. The differentiation into definite tissues, such as muscular, glandular, nervous, connective, etc., is incomplete and consequently there is but little co-operation and co-ordination among the parts of the body. The majority of sponges are of irregular shape, forming branching or encrusting structures attached to the bottom or to the submerged objects (fig. 1). Some of the sponges have, however, definite form and symmetry.

John Ellis (1765) was the first to demonstrate the animal nature of sponges by observing the water currents produced by a sponge and noticing the contractions on the surface of its body. For a long time sponges were grouped together with the Coelenterates (Linnaeus, Jean Lamarck, Georges Cuvier), until H. M. D. de Blainville (1816) placed them into a special group, Spongiaria, which he considered related to Protozoa. His idea received, however, no recognition from his contemporaries. The present name Porifera was created in 1836 by R. E. Grant, who devoted many years to the study of sponge morphology and anatomy. Separation of sponges from other multicellular forms (Metazoa) was proposed by T. H. Huxley (1875) and W. J. Sollas (1884), the view still held in 1945. Modern zoology places the sponges into a special branch of Metazoa called, after Sollas, Parazoa.

General Characters.-As the name Porifera implies, the surface of a sponge is covered with a multitude of minute openings or pores through which the current of water is maintained by flagellated cells located inside the sponge body. The water drawn in by the beating of the flagella passes through a complex system of canals and is expelled from several large vents, so-called oscula.

AFTER BIDDER IN "PROCEEDINGS OF THE S W. NATURALISTS" UNION

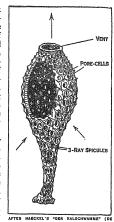

FIG. 1 .- COMMON SPONGES OF TEMPERATE SEAS A. Branched Finger Sponge (Chalina ceulata): B. Sea Fig (Suberites icus): C. Tow Sponge (Vibulinus stupesus): D. Axinelia dissimilis; E. Common Sponge (Leucandar ilstuloss): F. Sea Sponge (Donatal ylncurium); G. Mermald's Glove (Desmacidon fruticosum); H. Brittle Horry Sponge (Spongelia Iragilis)

The tissues are kept in place by a skeleton composed of mineral spicules or made of a mesh of elastic fibres (horny sponges). The simplest organization is found in the so-called ascanoid type of sponges represented by a few genera of calcareous sponges, Leucosolenia (fig. 2), Ascute, Ascyssa and Dendya. The latter genus approaches a more complex syconoid type. The vaselike symmetrical body of an ascanoid sponge is made of three layers of tissues forming the walls around a large central cavity (fig. 3). The outside covering consists of epidermis made of a single row of thin and flat cells. The central cavity is lined by a layer of collar cells or choanocytes, recognizable because of the presence of a contractile collar surrounding the base of a single long flagellum (fig. 4). The intermediate layer or mesenchyme (fig. 3, [7]) separating the collar cells from the epidermis consists of gelatinous material with spicules embedded in it and numerous amoeboid cells, the amoebocytes (fig. 3, [8]), freely wandering about. The incurrent pores or ostia are not simple holes in the epidermis but represent intracellular channels passing through special tubular cells, the so-called porocytes (fig. 5). Water is discharged through a large opening known as the osculum (fig.

In the next more complex type of organization, represented by the genus Sycon and called syconoid, the continuous layer of choanocytes is pushed outward at regular intervals to form pouchlike projections or radial canals. The walls of the canals may fuse, leaving between them narrow spaces, the inward-leading canals, lined with the surface epidermis. The spreading of the epidermis and mesenchyme to form a cortex (fig. 6) and the underlying subdermal spaces presents a further advance in the complexity of sponge organization and leads to a final or socalled leuconoid type. The latter type of organization and its numerous variations are represented in a vast majority of sponges. The leuconoid sponge (fig. 6, D) is characterized by clusters of small rounded flagellated chambers formed as a result of the outfolding of a continuous choanocyte layer of the ascanoid sponge. The choanocytes occur only in these chambers. The water is conveyed to the flagellated chambers through the ostia, subdermal spaces, inward-leading channels and pores (prosopyles) and is expelled through the outward-leading pores (apopyles) to the outward-leading canals, larger channels and is finally discharged through the oscula. A large layer of mesenchyme fills up the space between the canals and the flagellated chamber. The

large central cavity so prominent in the asconoid type is obliterated and the entire body of the sponge consists of a maze of water channels and flagellated chambers supported by a skeleton made of mineral spicules or spongin fibres. The development of a complex leuconoid type of organization is accompanied by a greater efficiency in producing and maintaining strong currents of water which provide the sponge with food and oxygen for respiration.

Size, Shape and Colour .--The size of sponges varies from a fraction of an inch, the usual length of small inconspicuous calcareous sponges of temperate seas (Sycon, Grantia), to huge masses of irregular or global shape several feet in diameter found in tropical and subtropical waters (Hircinia and many other horny sponges). Some of the sponges have definite symmetrical bodies, but the majority grow as irregular encrusting

AFTER HAECKEL'S "DER KALSCHWAMNE" GRUYTER & CO.)

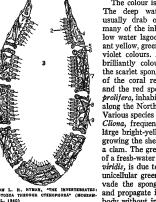

FIG. 2 .--- YOUNG LACE-CHALK (LEU-COSOLENIA PRIMORDALIS) "OLYNTHUS" STAGE, MAGNIFIED

masses or form large branching colonies. Of particular interest are many deep-sea sponges which display greater regularity of growth not found in their relatives inhabiting shallow waters. This secondary symmetry clearly shown in a remarkable species, Esperiopsis challengeri (fig. 7), is probably correlated with life in still water at great oceanic depths, which according to the generally accepted view the sponges invaded only in a comparatively recent time.

Sponges are completely devoid of organs of locomotion and are usually fastened to bottom, rocks, piles or other submerged

objects. Those living on muddy bottoms are anchored by roots consisting of bundles of long spicules (fig. 8).

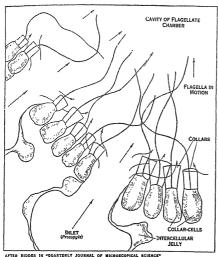

The colour is greatly variable. The deep water sponges are usually drab or brownish, but many of the inhabitants of shallow water lagoons display brilliant yellow, green, red, scarlet and violet colours. Among the most brilliantly coloured sponges are the scarlet sponge, Tedania ignis, of the coral reefs in Bermuda, and the red sponge, Microciona prolifera, inhabiting the estuaries along the North American coast. Various species of boring sponge, Cliona, frequently are found as lärge bright-yellow masses overgrowing the shell of an oyster or a clam. The greenish colouration of a fresh-water sponge, Spongilla viridis, is due to the presence of unicellular green algae which invade the sponge cells and live and propagate inside the sponge body without injuring their host (see Symbiosis).

FIG. A.—WALL OF FLAGELLATE CHAMBER OF THICK WALLED BANANACHALK (LEUCANDRA ASPERA); ARROWS SHOW DIRECTION OF CURRENTS

The chemical composition of the skeletal material serves to separate the calcareous, or chalky sponges, with the spicules composed of calcite, from siliceous and horny sponges in which the spicules are composed of siliceous and horny sponges in which the spicules are composed of siliceous and orders of siliceous sponges are not, however, clearly defined and no uniform system of classification has yet been agreed upon by zoologists. The classification commonly used in the United States is based on the works of E. Topsent, H. V. Wilson and M. W. deLaubenfels. The phylum Porifera is usually divided into three classes:

Class I.—Calcarea, the calcareous sponges. Skeleton is made of one-,three-,or four-rayed spicules of calcite.

Class II.—Hexactinellida, the glass sponges. Skeleton consists of a network of separate six-rayed (triaxon) siliceous spicules, finger-shaped flagellated chambers, no surface epithelium.

Class III.—Demospongiae. Sponges of leuconoid type with siliceous spicules, not of triaxon type, or of horny fibres or both. Spicules are differentiated into megascleres and microscleres; small flagellated chambers.

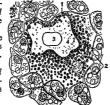

Subclass I.—Tetractinellida—with tetraxon spicules and no spongin. Spicules sometimes absent.

Sub class II.—Monaxonida large spicules (megascleres) of monaxonal type, spongin may be present or absent.

Subclass III.— Keratosa—the horny sponges. Skeleton consists of a meshwork of spongin fibres. Spicules absent.

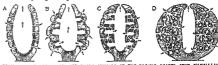

For more detailed study of sponge taxonomy, consult monographs and special publications listed by G. C. J. Vosmaer.

Histology.—The differentiation of cells in sponge tissues is much less pronounced than in the higher forms which possess various organs or systems such as digestive tracts, musculature, kidneys, etc., lacking in Porifera-

lining of the canals and central cavity. The pinacocytes, as these cells are called, form a single layer of epithelium consisting of flattened platelike elements with a large nucleus in the thicker portion of the cell. Sometimes the pinacocytes are provided with the cilia which help in maintaining the current of water. According to Wilson, in some of the sponges the true epithelium is replaced by a continuous "epithelioid membrane" or syncytium with scatered nuclei. The intake of water is regulated by means of special cells, porocytes, pierced by a canal and supplied with a highly con-

tractile diaphragm consisting of a thin sheet of cytoplasm stretched across the opening (fig. 5). The origin of porocytes, which by some of the investigators are considered as degenerate cells, has not yet been determined.

The flagellated cells or choanocytes lining the flagellated chambers are typical structures of sponge organization. They are easily recognized by transparent contractile collars and long flagella (fig. 4) attached to the cell body by means of a basal granule. In appearance and structure the choanocytes resemble the flagellated Protozoa of the family Craspedomonadidae. One representative of this group, a colonial protozoan Proterospongia (fig. 16), is regarded as a probable link between the sponges and flagellates.

The inner layer of a sponge body consists of transparent intercellular ground substance of variable consistency which gives support or acts as a scaffolding for widely separated mesenchyme cells. The latter are represented by different kinds of amoebocytes, or wandering cells, varying in size, character of pseudopodia, and type of inclusions. The mesenchyme also contains a large number of undifferentiated cells called archaeocytes, which may develop into more specialized types and apparently play an important role in regeneration. Mesenchyme cells which secrete spicules and spongin fibres are called scleroblasts. According to the type of skeleton they produce (fig. 12), they are designated as calcoblasts (secreting calcite

FIG. 7.—ESPERIOPSIS CHALLEN-GERI, A DEEP-SEA SPONGE WITH A SECONDARY SYMMETRY spicules), silocoblasts (producing siliceous spicules) and spongio- calcareous sponges CaCO3 content of ash varies from 84.9% to blasts (forming spongin fibres).

The sex cells, ova and spermatozoa, are apparently derived

from choanocytes which lose their flagella and collars and penetrate into mesenchyme. During this stage they look like true amoebocytes. Because of this similarity the old view maintained in the last century by F. E. Schulze, N. Polejaeff and O. Maas that the germ cells arise directly from amoebocytes cannot be discarded without further study.

True muscles in sponges are wanting. but special fusiform contractile cells, the mvocvtes. somewhat resembling smooth muscle cells of higher forms have been described. In certain species they form sphincters which regulate the afferent stream of water (fig. 9). Sensory and nerve cells are absent. The contractions of the surface of the body, or of the oscula, noticeable in some of the species, are the result of the direct stimulation of the pinacocytes and myocytes.

Skeleton.-Soft tissues are supported by a complex framework of hard spicules made of calcite (CaCO<sub>3</sub>) in calcareous sponges or of opal (SiO2nH2O) in siliceous sponges. In horny sponges the skeleton consists of a meshwork of elastic fibres made of spongin, an albuminoid of a highly complex chemical structure. The spicules vary in size, shape, and number of axes. Since the taxonomists use them as principal characters for the identification of sponges, elaborate terminology has been developed for designating various skeletal elements (fig. 10). In general there are two principal types: the large skeletal spicules, the megascleres which form the framework of the sponge body; and the small microscleres of variable and irregular shape scattered throughout the tissues.

Various classes of spicules are distinguished by the number of their axes or rays. Thus, monaxon designates the needlelike spicule with one axis; tetraxon has four rays emerging from one point and extending into different planes; three axes Fig. crossing at the right angles typical for DRY SPECIMEN (AFTER Hexactennellid sponges produce an element with six rays (fig. 11) or triaxon; several equal rays emerging from a central point characterize the polyaxons known TRAL CONE: 3, also as asters. The classification and the corresponding terminology become greatly

involved as various modifications caused by the loss of rays, bending of axes, etc., are taken into account and each type denoted by special term.

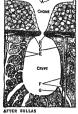

Mineral substance of a spicule is deposited around a central axis of organic material. In siliceous sponges the silica is laid in the form of concentric cylinders. Usually two scleroblasts (fig. 12) participate in the formation of a monaxon spicule which is laid down by one of them, the founder, while the other, the thickener, deposits additional mineral material. When the spicule is completed the two cells move apart. Several cells combine in secreting more complex spicules and spongin fibres (fig. 12. K, 0).

Chemical Composition.—Mineral constituents of the skeleton comprise a very large portion of sponge body. From 15% to 97% of the ash of siliceous sponges consists of SiO2, while in

8. - HYALONEMA, SCHULZE. 1887). HEXACTINNELID SPONGE WITH ROOT SPICULES: 1. ROOT SPICULES: 2, GAS-OTIC ZOANTHIDS ON ROOT 86.8%. Other mineral constituents include MgO, P2O5, Fe2O3Al2O3, Na2O, K2O, SO3, Si and minute quantities of Mn. Zn. B. Br. Cu and As.

The presence of relatively large quantities of iodine in dried commercial sponges, first demonstrated in 1819 by Andrew Fyfe, is of considerable scientific interest. It is known that iodine present in various species occurs in a combination with an organic compound of the skeleton known as iodospongin. The percentage of iodine in iodospongin varies from 1.5% to 4.86% in bath sponge (Euspongia sp.) to 8%-10% in Luffaria cauliformis. More detailed studies identified the iodine compound obtained from spongin as di-iodotyrosine, a complex which also contains bromine. Calcareous and siliceous sponges are, as a rule, poor in iodine; but the red sponge Microciona prolifera is apparently an exception, for according to the determinations made in 1933 by W. Bergman its iodine content comprises 0.3% of the

total dry weight. The physiological role of the iodine in sponge body is not known.

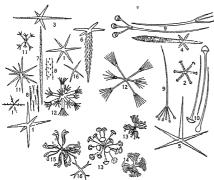

Physiology.—The water pumping mechanism of sponges consists of thousands of choanocytes which line the flagellated chambers. Because of their position inside the sponge body and small size, their action is difficult to observe. Only in calcareous sponges are the choanocytes relatively large and therefore observable with less difficulty. In action the flagellum of a choanocyte makes an undulating spiral movement which starts at its base and proceeds toward the tip. As the flagellum points toward the out-

ward leading pores, apopyles (fig. 4), each of its strokes draws

The pressure so produced stretches the walls of the flagellated chamber and is extended to the outward leading canals and central cavity. Apparently there is no co-ordination of the beating of the flagella, each choanocyte working more or less independently of the others. As a result of the movement of thousands of minute flagella the water is sucked into the flagel-

lated chambers through the dermal pores and inward leading canals and escapes through the outward leading canals and oscula. The velocity of current in each flagellated chamber is rather slow, but as thousands of tiny pumps deliver water into a relatively small number of vents, or oscula, the rate of the current increases. G. P. Bidder showed that in Leucandra aspera the current velocity at the osculum was about 8 cm. a second, while the velocity at the same moment past collar cells was only from 2 cm, to 4 cm, an hour. The pressure inside the oscula can be measured by inserting a glass tubing of corresponding diameter and observing the height of the water column above the surrounding level. By this method G. H. Parker found that hydraulic pressure in Stylotella was about 4 mm. These observations and other indirect methods can be used to compute the rate of pumping water by the whole sponge. According to Bidder, Leucandra aspera requires about 5 gal. of water a day and discharges it at a distance of about 9 in, from its body. A fingerlike branching sponge, Spinosella sororia, was observed by Parker to filter 1,575 litres of water per day. F. G. Walton Smith, working with cultivated horny sponges in the Bahamas, found that a wool sponge of 500 cu.cm. in volume pumped approximately 2 litres per minute. At this rate its daily requirement may be estimated at about 600 gal., but observations are still lacking to determine whether such a rate of pumping is maintained for 24 hours a day.

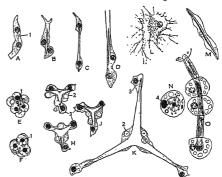

The flow of water through the body, maintained by the beating of the flagella, is regulated by the contractions and expansions of the oscula and dermal pores. In spite of the absence of any co-ordinating centre, the pumping mechanism works with great efficiency. The water sucked in by the sponge moves very slowly through the dermal pores, inward leading canals, and flagellated chambers, and provides the tissues with food and oxygen for respiration. Since the outgoing currents discharged through the oscula have much greater velocity, the water filtered by the sponge and contaminated with the products of its metabolism, is discharged far away and cannot be re-used. The presence of toxic or irritating substances dissolved in water is easily detected by the porocytes, which react by contracting their diaphragms

a little water and pushes it forward, gradually filling up the and closing the pores. In this way the sponge protects itself against possible injury. Structure and functioning of the pumping mechanism can be regarded as an efficient adaptation of sponges to the sedentary conditions of life in the ocean.

Food and Nutrition.-The food of sponges consists of minute organisms suspended in water. Bacteria probably play an important role in the feeding of horny sponges which frequently inhabit waters containing but small numbers of other micro-organisms in suspension. Thus, for instance, principal commercial species of sponges in the Bahamas are found on mud bottoms in waters containing very abundant bacterial flora but poor in plankton. The role of bacteria in the feeding of sponges has not been, however, adequately studied and requires further inves-

Ingestion and digestion of food can be observed by feeding the sponges with easily identifiable materials such as carmine or carbon powder, milk, starch grains or bacteria, and examining their tissues at regular intervals after feeding. As the flow of water passing from the narrow inward leading channels slows down after entering the flagellated chambers, the suspended particles settle and are caught by collar cells. In calcareous sponges the material entrapped in the collars of choanocytes becomes engulfed and digested by the cytoplasm. Some of the particles may be passed, however, to the amoebocytes surrounding the flagellated chambers (fig. 13). More complete division of functions exists in siliceous sponges. Here food is also caught by the choanocytes but digestion is accomplished only by amoebocytes.

Respiration.-Since special organs of respiration and circulation are lacking, the need for oxygen is supplied through direct exchange between the tissues and the surrounding water. Consequently, the rate of metabolism (O2 consumption) is controlled by the rate of exchange of water. Hyman found that the O2 consumption in Sycon may decrease by 80% when the oscula are closed. The observed rates per hour in this sponge vary from 0.04 to 0.16 ml. of oxygen per gram of fresh weight. The figures are of the same degree of magnitude as those observed for many other marine invertebrates. Sponges have no organs of excretion. Products of their metabolism and indigestible material,

-SECRETION OF MONAXON, A-D. AND TRIRADIATE (E-K) SPIC-ULES (AFTER WOODLAND, 1905); L, CALCOBLAST (AFTER DENDY, 1893); M, SILICEOUS MONAXON OF FRESH-WATER SPONGE (AFTER EVANS, 1901); N, O. SECRETION OF SPONGIN IN RENIERA (AFTER TUZET, 1932); 1. SPICULE; 2, FOUNDER; 3, THICKENER; 4, SPONGIN MASS

ejected by the amoebocytes, are discharged with the outgoing currents.

Poisonous and Injurious Sponges .- The surface of many sponges is slimy because of the excretion of mucous, which may cause unpleasant but not dangerous irritation of the skin. For instance, the scarlet sponge of the Bermuda islands, Tedania ignis, when handled with naked hands, causes painful dermatitis. The nature of the active substance is not known. Of special in- still arranged in one plane. After the 32-cell stage has been terest are the boring sponges of the genus Cliona, widely distributed in the coastal water of North America. As the name indicates, the sponge bores through the shells of oysters and other molluscs and in case of severe infestation may destroy them. The method by which the sponge makes its long and branching passages in the shell substance is not known. Secretion of acid has been suggested but not corroborated by observation. Studies conducted by P. S. Galtsoff and V. Pertzoff in 1926 showed, however, that the suspension of cells of Cliona behaves as a much stronger acid than that of the nonboring sponge Microciona. Mechanical action may also be involved in boring, but the process has not yet been adequately studied.

Regeneration .- The power of regeneration, i.e., the ability to restore lost parts, is very high in sponges. Not only is a piece cut off from a body capable of growing into a complete sponge, but the cells separated by squeezing a piece of sponge through fine silk cloth, and suspended in water, reunite and develop into a new spenge. The phenomenon discovered by Wilson in 1907 is of considerable theoretical interest. It was thought first that the development of a new sponge from reunited masses is to a certain extent similar to the development of an embryo, and that the separated cells undergo dedifferentiations and return to the embryonic state. It was shown by P. S. Galtsoff that certain cells retain their morphological characteristics and the first steps in regeneration are accomplished by the sorting out and rearrangement of the old cellular material.

Under unfavourable conditions sponges collapse, disintegrate and leave only small reduction bodies which consist of a mass of amoebocytes covered by epidermis. With the return of normal conditions these bodies are capable of developing into complete sponges.

Asexual Reproduction .-- All fresh-water and some marine sponges reproduce by means of gemmules, small, hard and rounded bodies consisting of a mass of archaeocytes laden with reserve food and surrounded by a columnar layer of flattened cells (fig. 14). The formation of gemmules in fresh-water sponges begins with the gathering of amoebocytes, which are joined by special nurse cells, the trophocytes, carrying food reserves. Some of the amoebocytes arrange themselves in columnar layers and secrete two concentric membranes around the central core. The inner membrane is usually much thicker than the outer. The growing gemmule is invaded by the scleroblasts, which secrete the so-called amphidisks, the spicules having the appearance of ordinary cuff links, and place them between the two membranes of the columnar layer. The amazing part of cell behaviour is that when the gemmule is completed, the columnar cells, nurse cells and scleroblasts depart.

Fresh-water sponges usually disintegrate with the onset of cold weather but gemmules survive and hatch in spring. The content of the gemmule emerges through a small opening, the micropyle (fig. 14, [11]), and develops into a new sponge through the differentiation and rearrangement of the archaeocytes.

Sexual Reproduction.-Hermaphroditism is apparently prevalent among the sponges, although in some of them the sexes are separate. Fertilization of the ovum, studied by J. B. Gatenby in calcareous sponges, is rather unique, for the sperm brought in by current of water first enters the choanocyte which acts as a nurse cell. The fusion of the choanocyte with the nearest egg, which occupies a position close to the flagellated chamber, sets the sperm free. Insemination is then accomplished in a regular manner.

Similar process was described by O. Tuzet in siliceous sponges, with the only difference that sperm enters the amoebocyte, which in turn transfers it to the egg.

Detailed information about the breeding periods of sponges is lacking. In the commercial sponges of the Bahamas (sheepswool and velvet) breeding takes place all the time, but the greatest proportion of specimen with embryos ready for release were found by F. G. W. Smith in March and April.

Development.—The fertilized egg divides into two, four and eight blastomeres which surround a central cavity while they are

reached the divisions become somewhat irregular. At this time the embryo, called now blastula, has a shape of an oval vesicle, one end of which is flattened and the other rounded. The central cavity of the blastula opens to the exterior at the flattened sur-

H. HYNAN, "THE INVERTEBRATES: THROUGH CTENOPHORA" (MCGRAW-FIG. 13 .-- AMOEBOCYTE OF A CAL-

BON PARTICLES FROM CHOANG-CYTES (AFTER POURBOIX, 1933): 1. CARBON PARTICLES

face. This opening or pore is surrounded by the cells distinguishable from the others by heavy granular inclusions, while the remaining cells are columnar and have long flagella.

Rapid proliferation of granular cells produces a thick mass which bulges into the central cavity (fig. 15A). By this time the embryo, by means of the flagella, forces its way into the nearest CAREOUS SPONGE RECEIVING CAR- flagellated chamber and escapes through the osculum. Apparently through the absorption of water, the layer of invaginated

cells is forced out and the embryo acquires an oval shape. The sponge larva at this stage is called amphiblastula, from Greek, amphi, around or on both sides and blastos, germ, (fig. 15, B). One half of it consists of columnar and brightly pigmented cells with long flagella, the other half is made of round granular cells. The amphiblastula type of larvae occurs in all families of sponges and is, therefore, typical of the entire group. The larva swims with its ciliated end forward. After a few days of free life it settles on a smooth surface of a stone or shell, with its ciliated portion directed downward, and almost immediately flattens. The ciliated cells become invaginated and the central cavity of the larva, the blastocoele, reduced to a narrow slit. The larva now becomes attached to the substratum. At this stage it consists of two layers. The granular cells form the outer covering and the flagellated cells line the inside cavity. Very soon the flagellated cells develop characteristic collars and are transformed into choanocytes. The appearance of the granular substance between the two layers, the formation of the pores and osculum, and the secretion of spicules complete the development. At this stage the young sponge is usually referred to as "olynthus." Its final transformation into an adult sponge is a matter of continuous slow growth and rearrangement of cellular elements. Although the details of the development may vary in different classes and families the essential steps are similar in all of them.

Individuality of Sponges.-Lack of a central regulatory or co-ordinating organ, great variability in shape or form, and remarkable regenerative power, make it difficult to decide whether sponges are individuals or colonies. This theoretical question, much debated by the zoologists of the last century, has not yet been satisfactorily settled. It is generally considered that the osculum with the contributing part of the canal system is an individual element or a "person," and that several of these units are combined in a colony of individuals grown together and performing common functions. The fact that the osculum controls the flow of water through the adjacent part of the body and is the most conspicuous part of the sponge anatomy, seems to give weight to this view. The boundaries of individual units are, however, indistinct and their individuality is of very vague nature. It is remarkable that, in spite of the absence of central organs, many species of sponges developed very definite shape and symmetry. Their skeletons also show progressive complexity from a rather simple arrangement of spicules to a very complicated symmetrical framework built according to a definite structural pattern.

Relationship.—On the basis of our knowledge of the anatomy and histology of sponges, it is reasonable to suppose that this group evolved from colonial choanoflagellate Protozoa similar to Proterospongia (fig. 16). In the subsequent evolutionary process sponges formed a separate branch of Metazoa which failed to develop higher grades of organization characterized by the formation of a head, nervous system, organs of digestion, circulation and respiration present in other multicellular forms. The sponges

retained their ancestral protozoan features in the structure of choanocytes, in the intracellular digestion, and in the mode of production of the skeleton, the elements of which are secreted by single cells or group of freely moving cells. Progressive evolution in sponges consisted chiefly in the perfection of the canal system and in developing a more complex skeleton. Sponges appeared very early in geological history, for their spicules are found in the upper Cambrian deposits.

Ecology .- The distribution of sponges is world-wide. They inhabit all the oceans, seas, freshwater lakes and rivers, and grow on all kinds of bottoms from tidal flats to abvssal depths. Their most favoured environment is,

however, that of rocky or hard bottom along the seashores and in coral-reef lagoons. The greatest percentage of more than 2,500 known species of sponges is confined to this habitat. Close association with other invertebrates seems to be one of the most interesting features of sponge ecology. Porous structure and numerous cavities of sponge body provide safe abode for hydroids, worms, shrimps, crabs, molluscs and other invertebrates. Some of these animals invade the sponges accidentally, while others form more permanent association. Thus, thousands of shrimps of the family Alpheidae are found in every loggerhead sponge of the British West Indies. The young shrimp of the genus Spongicola enter the cavity of glass sponges (Hexactinellida), where they live in pairs and soon become imprisoned because their grown-up bodies cannot escape through the small openings of the sieve plates guarding the oscula of their host. Sponges of the family Suberitidae are often found overgrowing snail shells occupied by hermit crabs. The relation is obviously advantageous for both parties. The crab is well protected by sponge spicules and its repelling taste, while the sponge is carried about by the crab and gets better opportunities for feeding. Crabs of the genus Dromia break pieces of sponges with their legs and place them on their backs where the sponge becomes implanted.

Sponges are apparently distasteful to other animals and are usually avoided. They are eaten only by a few species of nudibranch molluscs.

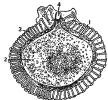

Diseases.-Widespread mortalities frequently occur among commercial sponges. In the fall of 1938 a devastating disease which rapidly spread from the Bahamas to Cuba, British Honduras, Mexico and the east coast of Florida almost completely destroved the velvet sponge and killed more than 70% of wool sponges. The disease was associated with an infection by a funguslike micro-organism tentatively identified as Spongiophaga. No control measures were suggested to check the infection except the closing of grounds to commercial fishery.

Utilization of Sponges.-Horny sponges (Keratosa) have been in use from the earliest times. In ancient Greece, mothers pacified their crying babies by giving them a piece of sponge soaked in honey. According to Pliny, sponges were employed as paint brushes and mops, and Roman soldiers carried with them a piece of sponge to be used instead of a drinking vessel. This custom makes comprehensible the manner in which vinegar was offered to Christ on the cross-in a soaked sponge (Mark XV, 36). In the 13th century A.D. Arnold of Villa Nova introduced the "burnt sponge" as medicinal preparation to be used internally in scrofula, a term which usually refers to tuberculosis of lymphatic glands, but formerly also covered other diseases. The therapeutic effect, if any, was possibly due to a high content of iodine present in the carbonized sponge in the form of NaI.

TABLE 1.—Common and Scientific Names of Principal Commercial Sponges						
Common Name	Scientific Name	Fishing Areas				
Turkey cup; Turkey solid, Fine Levant; Silks	Euspongia officinalis molissima	Eastern Mediterranean, Tunis				
Turkey toilet	Euspongia officinalis adriatica	Adriatic, Tunisia, Eastern Mediter-				
Zimocca	Euspongia simocca	Adriatic, Dardanelles, Greece, Egypt, Tripoli, Tunisia				
Elephant's ear	Euspongia officinalis lamella	Provence, Dalmatia, Egypt, Tunisia, Algeria				
Honeycomb; bath	Hippiospongia equina elastica	Mediterranean				
Wool; sheepswool	Hippiospongia lachne	Florida, West Indies, Honduras				
Velvet	Hippiospongia grossypina	Bahamas, Honduras, Cuba				
Yellow	Spongia barbara. Probably also other species					
Grass	Spongia graminea	Florida, Bahamas, Cuba, Mexico, British Honduras				
Glove	Hippiospongia canaliculata var. flabel- lum	Florida, Bahamas				
Reef	Spongia obliqua, and probably S. aga- ricina and other species	Florida				
Hardhead	Spongia dura, S. agaricina corlosia and probably other species	Bahamas, British Honduras, Haiti				

In modern times, besides obvious toilet and household uses, sponges are required for scores of purposes such as the manufacture of special surgical and hygienic preparations, leather dressing, application of glaze to fine pottery, scouring and sponging of cloth. They are extensively employed by tile and bricklayers, painters, decorators, lithographers, jewellers and silversmiths. Probably the largest number of sponges is used for washing railroad cars and automobiles.

Industrial Types.—The trade recognizes several types which correspond to different species listed in Table I. There is, how-

259

Good commercial sponges occur also in the Philippines and in Australia. Contribution to the world trade of sponges from these countries is, however, insignificant. Several varieties of horny sponges of the Hawaiian Islands are not suitable for the trade because of their extreme softness and lack of durability.

The annual world production FRESH-WATER SPONGE, EPHYDATIA, of sponges in 1938, the last "nor-WITH INNER MEMBRANE (AFTER mal" year before World War II, was estimated at 2,102,400 lb., valued at \$2,556,398. The U.S. contributed 28.8% of the total catch and 41.9% of the total

value. The contributions of the principal sponge producing countries for the years 1938 and 1939 are shown in Table II.

In 1943 the production of sponges in the U.S. dropped to 3e5,-822 lb., almost one half of that of 1938, but the value increased to \$2,305,070.

The most valuable of the commercial sponges are the Turkey Cup and Turkey Toilet. Best specimens of these varieties sometimes are sold as high as \$50 per pound. The total quantity of these high priced sponges offered on the world's market is, however, insignificant in comparison with the wool sponge, which in the western hemisphere constitutes about 80% of the catch.

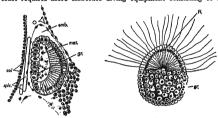

Fishing Methods.—Commercial sponges are taken from the bottom of the sea from tidal level to a depth of about 200 ft. In the shallow inshore waters the sponges are picked by means of a two- or three-pronged hook attached to a long pole. The hooker, as the fisherman is called, operates from a small skiff which he pushes by pole. When the sponge is noticed, sometimes at the depth of 25 or even 30 ft., the pole is lowered and the hook

placed under the sponge, which is then detached from the bottom by a slight pull and is brought to the surface. This primitive and slow method of fishing can be used only in clear and calm inshore waters. Nude diving, without equipment of any kind, is still practised in Greece, along the Libyan coast and in the Philippines. Fishing in the deeper water near Greece and off the Florida coast requires more elaborate diving equipment consisting of a

regular diving suit, scaphander and boat with mechanically operated air pump. A small dredge, known as "gangave," is used in Libya. The implement is very destructive and its use is prohibited in the western hemisphere. Sponges caught in the Bahamas, Cuba, Turks and Caicos islands are picked exclusively by hookers

Sponges gathered by divers or hookers are cleaned aboard the boat or placed in "crawls," i.e., small ponds along the shore where the soft parts of sponge tissues rot. The remaining skeletons are

AND SPONGES

taken out, squeezed, rinsed in water, strung in clear sea bunches and dried in air.

An interesting feature of the sponge industry in the U.S. is a co-operative selling association, the Tarpon Springs Sponge exchange, which auctions all the sponges brought by fishermen. A similar organization, but under direct control of the colonial government, was established in Nassau. Bahamas. The auction is LATE CONSIDERED AS A PROBABLE rather unique, for the selling is LINK BETWEEN THE FLAGELLATES conducted in complete silence. As the buyers examine the vari-

ous lots of sponges they write down on a piece of folded paper the highest price they are willing to pay and hand it to the auctioneer. When the auction is over the bids are opened by the representative of the association and the highest bidder is awarded the sponges, provided the price is acceptable to the owner. Before reaching the retail market sponges are sorted, cleaned, bleached and sometimes dyed.

Conservation .-- At the end of World War II, no system of conservation or management of natural sponge resources was being exercised by any government. The only protection effective in the U.S., Bahamas, Turk and Caicos islands consisted in the enforcement of the size limit laws which prohibit the taking and selling of sponges less than five inches in diameter.

Sponge Farming or Sponge Culture.-Because of their high regenerative power, sponges can be grown from small cuttings. Experiments in this method of cultivation were made at the end of the last century by H. F. Moore in Florida and were also conducted on a larger scale in the estuarine waters of Tunisia. The practicability of the method was definitely demonstrated by large scale operations conducted by the British government in the West Indies and British Honduras. From 1935 to 1939 more than 140,000 sponges were growing on government grounds in the Bahamas, and more than 700,000 cuttings were planted at Turneffe, British Honduras. Unfortunately, the mortality of 1938-39 was particularly severe among the cultivated sponges and the beds were almost completely destroyed.

The farming method consists in growing sponges from rectangular slices about 2" x 4" x ½", cut with a very sharp knife from a healthy sponge and attached with a string to a piece of rock or cement disk. The cuttings are immediately placed in water. From 16 to 32 pieces can be cut from one adult wool sponge of six to eight in. in diameter. Regeneration begins immediately and the sponge, firmly adhering to its base, grows as a well-shaped round specimen. In the Bahamas, sponges grown from cuttings reach marketable size in about four years.

If correctly conducted, sponge culture may become a profitable occupation, but because of the scarcity of suitable inshore grounds it cannot replace the fishery on natural grounds. The possibility of propagating sponges through sexual reproduction has not vet been explored.

SPONSOR, one who stands surety for another (from Lat. spondere, to promise), especially in the rite of Christian baptism, a godfather or godmother. The practice originated not in infant baptism, but in the custom of requiring an adult pagan who offered himself for the rite to be accompanied by a Christian known to the bishop, who could vouch for the applicant and undertake his supervision, thus fulfilling the function performed in the Eleusinian mysteries by the mystagogus. The Greek word for the person undertaking this function is araboxos, to which the Latin susceptor is equivalent. The word "sponsor" in this ecclesiastical sense occurs for the first time, but incidentally only, and as if it were already long familiar, in Tertullian's treatise De baptismo (ch. 18), where, arguing that in certain circumstances baptism may conveniently be postponed, especially in the case of little children, he asks, "For why is it necessary that the sponsors like-

wise should be thrust into danger, who both themselves by reason Jan. 14, 1851. of mortality may fail to fulfil their promises, and may also be disappointed by the development of an evil disposition [in those for whom they become sponsors?"

The sponsors here alluded to may have been in many cases the actual parents, and even in the 5th century it was not felt to be inappropriate that they should be so; Augustine, indeed, in one passage appears to speak of it as a matter of course that parents should bring their children and answer for them "tanquam fidejussores" (Epist. . . . ad Bonif. 98), and the oldest Egyptian ritual bears similar testimony. Elsewhere Augustine contemplates the bringing of the children of slaves by their masters. and of course orphans and foundlings were brought by other benevolent persons.

The comparatively early appearance, however, of such names as compatres, commatres, propatres, promatres, patrini, matrinae, is of itself sufficient evidence, not only that the sponsorial relationship had come to be regarded as a very close one, but also that it was not usually assumed by the natural parents. How very close it was held to be is shown by the Justinian prohibition of marriage between godparents and godchildren. On the other hand, the anciently allowable practice of parents becoming sponsors for their own children, though gradually becoming obsolete, seems to have lingered until the 9th century, when it was at last formally prohibited by the council of Mainz (813). For a long time there was no fixed rule as to the necessary or allowable number of sponsors and sometimes the number actually assumed was large. By the council of Trent, however, it was decided that one only, or at most two, these not being of the same sex, should be permitted.

The rubric of the Church of England, that "there shall be for every male child to be baptized two godfathers and one godmother, and for every female one godfather and two godmothers," is not older than 1661; the sponsors are charged with the duty of instructing the child, and in due time presenting it for confirmation. In the Roman Catholic Church the spiritual relationship established between the sponsor and the baptized, and the sponsors and the parents of the baptized, constitutes an impediment to marriage. (See MARRIAGE, LAW OF: Canon Law.)

SPONTINI. GASPARO LUIGI PACIFICO (1774-1851), Italian composer, was born on Nov. 14, 1774, at Majolati (Ancona) in Italy. He was the son of a poor cobbler and was intended for the priesthood. But he obtained lessons from Kapellmeister Quintiliani, and in 1791 went to the Conservatorio de' Turchini at Naples, where he studied under G. Paisiello, D. Cimarosa and Fiorivanti. By 1799 he had already written and produced eight operas, After becoming court composer to King Ferdinand of Naples in this year an intrigue with a princess of the court compelled Spontini to leave Naples in 1800. In 1803 he settled in Paris, where he had no success until the production of Milton, a one-act opera, in 1804. Thereafter his powers and ambitions steadily developed, being manifested to the full for the first time in La Vestale, produced on Dec. 15, 1807. Ferdinand Cortez was received with equal enthusiasm in 1809; but Olympia (1819) had less success.

Spontini had been appointed director of the Italian opera in 1810; but his quarrelsome and grasping disposition led to his summary dismissal two years later, and though reinstated in 1814, he voluntarily resigned his post soon afterward. In 1820 he settled in Berlin by invitation of Frederick William III, commissioned to superintend all music performed at the Prussian court and compose two new grand operas, or three smaller ones, every three years. But he began by at once embroiling himself with the intendant, Count Brühl. La Vestale, Ferdinand Cortez and Olympia-the last two entirely remodelled-were produced with great success in 1821. But Spontini's fame was entirely eclipsed by the appearance of Carl Weber's Der Freischütz. A new opera, Nourmahal, founded on Thomas Moore's Lalla Rookh, was performed in 1822, and another, entitled Alcidor, in 1825; and in 1826 Spontini began the composition of Agnes von Hohenstaufen, (produced in 1829), which undoubtedly will rank permanently as his greatest work.

Dismissed from his court position in 1841, he settled in Paris. In 1850 he retired to his birthplace, Majolati, and died there on

SPOON, a table implement, bowl-shaped at the end, with a handle varying in length and size. From the derivation of the word the earliest northern European spoon would seem to have

BY COURTESY OF THE METROPOL-OF THE CHOU DYNASTY

been a chip or splinter of wood; the Greek κοχλιάριον (Lat. cochleare) points to the early and natural use of shells, such as are still used by primitive peoples. Examples are preserved of the various forms of spoons of ivory, flint, slate and wood many of them carved with the symbols of their religion, used by the ancient Egyptians. The spoons of the Greeks and Romans were chiefly made of bronze and silver, and the handle usually takes the form of a spike or pointed stem. Mediaeval spoons for domestic use were commonly made of horn or wood, but brass, pewter and "latten" spoons appear to have been common about the 15th century. The full descriptions and entries relating CHINESE BRONZE SPOONS to silver spoons in the inventories of the royal and other households point to their

special value and rarity. The earliest English reference appears to be in a will of 1259. In the wardrobe accounts of Edward I for the year 1300 some gold and silver spoons marked with the fleur-de-lis, the Paris mark, are mentioned. One of the most interesting mediaeval spoons is the coronation spoon used in the anointing of the sovereign. The sets of spoons popular as christening presents in Tudor times, the handles of which terminate in heads or busts of the apostles, are a special form to which antiquarian interest attaches. (See Apostle Spoons.) The earlier English spoon handles terminate in an acorn, plain knob or a diamond: at the end of the 16th century the baluster and seal ending becomes common, the bowl being "fig shaped." At the Restoration the handle becomes broad and flat, the bowl is broad and oval and the termination is cut into the shape known as the pied de biche, or hind's foot. In the first quarter of the 18th century the bowl becomes narrow and elliptical, with a tongue or "rat's tail" down the back, and the handle is turned up at the end. The modern form, with the tip of the bowl narrower than the base and the rounded end of the handle turned down, appeared about 1760.

See C. J. Jackson, "The Spoon and its History," in Archaeologia (1892), vol. liii; also Cripps, Old English Plate. SPOONBILL, any one of six species of moderately large

wading birds constituting the subfamily Plataleinae and, with the ibises (q.v.), the family Threskiornithidae (order Ciconiiformes). The head is partly or entirely bare, the plumage white (except in the roseate spoonbill). often with a rosy tinge, some with a nuptial crest or foreneck plumes. They differ from ibises in having a long nearly straight bill, narrow in the middle and broad and flat at the end, which they immerse in feeding, swinging it from side to side and sifting small animals from the mud and water of estuaries, salt-water bayous and lakes. In flight they flap steadily, usually without sailing. They breed in colonies, often with ibises and herons, build a good nest of sticks some-

BY COURTESY OF THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES THE ROSEATE SPOONBILL (AJAIA AJAJA), FOUND ONLY IN TROPICAL AND SUBTROPICAL AMERICA

times lined with leaves or bark, among reeds or in a low bush or tree about 10 ft. up, and lay three to five white eggs blotched with reddish-brown. The beautiful roseate spoonbill (Ajaia ajaja), 32 in., head and throat bare, legs red, is deep pink with neck and upper back white, wing coverts and tail coverts deep carmine and tail and sides of breast tawny-buff. It ronges from the gulf states, West Indies and central Mexico to the Argentine and Chile. In many places it was exterminated by plume hunters. The yellow-legged spoonbill (Platibis flavipes) of Australia is white with foreneck straw-coloured, has the forehead, upper throat and bill yellow. The crested white spoonbill (Platiblea leucorodia), 24 in, with cinnamon-buff on the foreneck, breeds in marshes of central and southern Europe and Asia, south to Egypt, India and Formosa; the black-billed spoonbill (P. regia), white with black wing-tips and black legs, from Australia and New Zealand to New Guinea, Celebes, Moluccas and Solomons; the lesser spoonbill (P. minor), from Korea and southern Japan to southern China and the Philippines; the African spoonbill (P. alba), over Africa south of the Sahara and in Madazasca.

(G. F. Ss.) SPORADES, the scattered islands of the Greek Archipelago, distinguished from the Cyclades, which are grouped round Delos, and from the coastal islands of Europe and Asia. Ancient and modern writers differ as to the list. The Doric Sporades-Melos, Pholegandros, Sikinos, Thera, Anaphe, Astypalaea and Cos-were by some considered a southern cluster of the Cyclades. In modern times the name Sporades is applied to two groups: The northern Sporades lie northeast of Negropont (Euboea), Skiathos, Skopelos and Ikos being included in the department of Magnesia, and Scyros (q.v.) in that of Euboea. Scyros has a fine harbour. Skiathos is beautifully wooded; the town overlooks an excellent harbour. Skopelos is also well wooded. Almost every householder in both islands is the owner, joint owner or skipper of a sailing ship. The southern Sporades, lying off the southwest of Asia Minor, formerly included in the Turkish vilayet of the "Islands of the White Sea," are as follows: Icaria, Patmos (q.v.), Leros, Calymnos, Astypalaea (Astropalia or Stampalia), Cos (q.v.) (Turk. Stanko), Nisyros, Tilos or Episcopi, Syme, Khalki, Rhodes (q.v.) and many smaller isles.

See C. Bursian, Geographie von Griechenland (Leipzig, 1862-71), ii, 348 ff.; L. Ross, Reisen auf den Griechischen Inseln (1840-45).

SPOROZOA, a group of parasitic Protozoa which produce unicellular spores within a tough envelope or cyst. Since formerly various Protozoa, which had only this character in common and were not truly related to one another, were classed with the Sporozoa, some protozoalogists have split up the class Sporozoa into two classes, Amoebosporidia and the true Sporozoa. For further particulars see Protozoa.

SPORTS, ARTICLES ON. Almost all varieties of indoor and outdoor sport have separate articles in this Encyclopedia. Among the chief are: Angling; Athlepig Sports; Baseball; Billiards; Bowling; Boxing; Bridge; Bullfight; Camping; Charade; Chess; Conjuring; Coursing; Chicket; Sycling; Palconry; Football; Game; Games, Cycling; Driving; Falconry; Football; Game; Classical; Gole; Gymkhapa; Gymnastics and Gymnasium; Hockey; Horsemanship and Riding; Horse; Racing and Breeding; Hunting; Hurdling; Jumping; Lacrosse; Lawn Tennis and Tennis; Mountaineering; Patience; Pigeon-Flying; Pig-Sticking (Hog-Hunting); Pinocle; Poker; Poll-Guglism; Rackets; Roller-Skating; Rowing; Running;

Shooting; Skating; Ski; Swimming; Tobogganing; Ventriloquism; Walking Races; Water Polo; Weight Throwing; Whist; Wrestling; and Vachting.

SPORTS, THE BOOK OF, or more properly the DECLARATION OF SPORTS, an order issued by James I in 1617 on the recommendation of Thomas Morton, bishop of Chester, for use in Lancashire, where the king on his return from Scotland found a
conflict on the subject of Sunday amusements between the Puritans and the gentry, many of whom were Roman Catholics. Permission was given for dancing, archery, leaping, vaulting and
other harmless recreations, and of "having of May games, Whitsum ales and morris dances, and the setting up of maypoles and
other sports, therewith used, so as the same may be had in due
and convenient time without impediment or neglect of divine
service, and that women shall have leave to carry rushes to church
for the decorating of it." On the other hand, "bear and bull-baitlag, interludes, and (at all times in the meane sort of people by

law prohibited) bowling" were not to be permitted on any Sunday (Wilkins, Concilia, iv, 483).

In 1618 James transmitted orders to the clergy of the whole of England to read the declaration from the pulpit; but so strong was the opposition that he prudently withdrew his command (Wilson, in Kennet, ii 709; Thomas Fuller, Charch History, v, 452). In 1633 Charles I not only directed the republication of his father's declaration (Rushworth, ii, 193), but insisted upon the reading of it by the clergy.

Many of the clergy were punished for refusing to obey the injunction.

With the fall of Laud all attempts to enforce it necessarily came to an end.

SPOTSWOOD, ALEXANDER (1676-1740), American colonial governor, was born of an old Scots family, in Tangier, Africa, in 1676.

He served as aide to Marlborough in the War of the Spanish Succession, and was wounded at Blenheim. He was appointed lieutenant governor of Virginia in 1710, and was received with enthusiasm, because he brought to the colony the privilege of habeas corpus; his term as governor closed in Sept. 1722, but he remained in Virginia, living near his ironworks in Germanna, a settlement of Germans, on the Rapidan in Spotsylvania county (named in his honour); and he was deputy postmaster general of the colonies from 1730 to 1739.

He was the first representative of the British government in America who fully appreciated the value of the western territory. As governor he recommended the establishment of a Virginia company to carry on trade with the Indians, he urged upon the provincial government and also upon the British authorities the wisdom of constructing forts along the frontier, and he personally organized and conducted in 1716 an exploring expedition into the Shenandoah valley.

He developed the iron industry of Virginia, promoted the religious education of the Indians, and tried to advance the interests of education, especially at the College of William and Mary. He died at Annapolis, Md., June 7, 1740.

See R. A. Brock (ed.), "The Official Letters of Alexander Spotswood" (with a memoir), in The Collections of the Virginia Historical Society (1882-85).

SPOTSYLVANIA, a county of Virginia, U.S.A., so called after Alexander Spotswood (g.v.), lieutenant governor of Virginia in 1710-22, who owned extensive estates and mines therein. It is bounded on the north by the Rapidan and Rappahannock rivers and on the south by the North Anna. It is celebrated as containing several of the most famous battlefields of the Civil War—Fredericksburg, Chancellorsville, the Wilderness and particularly that of Spotsylvania Courthouse, where the armies of U. S. Grant and Robert E. Lee fought for two weeks (May 8-21, 1864). Pop. (1950) 11,900.

SPOTTED JEWFISH (Promicrops itaiara), an immense marine bass (fam. Serranidae) found on the coasts of tropical America, which sometimes at-

tains a length of 8 ft. and a weight of about 700 pounds.
The adult is dull olive-brown

The adult is dull olive-brown in colour, with faint spots and bands; the young are yellowish-green, with dark crossbars and spots about the head. The South Pacific iewfish reaches 12 ft.

SPOTTISWOODE (Sport-TISWOOD, SPOTTSWOOD or Sports-WOOD), JOHN (1565-1639), CROPS

BY COURTESY OF THE M.T. ZOOLOGICAL SO-CIETY
THE SPOTTED JEWFISH (PROMI-CROPS ITAIARA)

archbishop of St. Andrews and historian of Scotland, eldest son of John Spottiswood, minister of Calder and "superintendent" of Lothian, was born in 1565. He was educated at Glasgow university (M.A. 1581), and succeeded his father in the parish of Calder in 1583. In 1601 he attended Ludowick, duke of Lennox, as his chaplain, in an embassy to the court of France, returning in 1603. He followed James to England on his accession, but was the same year nominated to the see of Glas-

Oct. 1610. On May 30, 1605, he became a member of the Scottish privy council. In 1610 he presided as moderator over the assembly in which presbytery was abolished, in 1615 he was made archbishop of St. Andrews and primate of Scotland. and in 1618 procured the sanction of the privy council to the Five Articles of Perth with their ratification by parliament in 1621. In 1633 he crowned Charles I at Holyrood. In 1635 he was appointed lord chancellor of Scotland, an office which he retained till 1638. He was a spectator at the 11ot of St. Giles', Edinburgh, on July 23, 1637, endeavoured in vain to avoid disaster by concessions, and on the taking of the Covenant perceived that "now all that we have been doing these thirty years past is thrown down at once." He escaped to Newcastle, was deposed by the assembly on Dec. 4, on trivial charges, and died in London on Nov. 26, 1639, receiving burial in Westminster abbey. His most considerable work was The History of the Church and State of Scotland (London, 1655, seg.).

See the accounts prefixed to the first edition of Spottiswoode's History of Scotland and to that published by the Spottiswoode society in 1851; also David Calderwood's Hist. of the Kirk of Scotland (1842-49).

SPOTTISWOODE, WILLIAM (1825-1883), English mathematician and physicist, was born in London on Jan. 11, 1825. His father, Andrew Spottiswoode, who was descended from an ancient Scottish family, represented Colchester in parliament for some years, and in 1831 became junior partner in the firm of Eyre & Spottiswoode, printers. William was educated at Laleham, Eton, Harrow and Balliol college, Oxford. His bent for science showed itself while he was still a schoolboy, and indeed his removal from Eton to Harrow is said to have been occasioned by an accidental explosion which occurred while he was performing an experiment for his own amusement. At Harrow he obtained in 1842 a Lyon scholarship, and at Oxford in 1845 a first-class in mathematics, in 1846 the junior and in 1847 the senior university mathematical scholarship. In 1846 he left Oxford to take his father's place in the business, in which he was engaged until his death. In 1847 he issued five pamphlets of original mathematical work; and from this time scarcely a year passed in which he did not give to the world further mathematical researches. In 1856 Spottiswoode travelled in eastern Russia, and in 1860 in Croatia and Hungary; of the former expedition he has left an interesting record entitled A Tarantasse Journey through Eastern Russia in the Autumn of 1856 (London, 1857). In 1870 he was elected president of the London Mathematical society. In 1871 he began to turn his attention to experimental physics, his earlier researches bearing upon the polarization of light and his later work upon the electrical discharge in rarefied gases. He wrote a popular treatise upon the former subject for the "Nature" series (1874). In 1878 he was elected president of the British association, and in the same year president of the Royal society, of which he had been a fellow after 1853. He died in London of typhoid fever on June 27, 1883, and was buried in Westminster abbey.

SPRAT, THOMAS (1635-1713), English divine, was born at Beaminster, Dorsetshire, and educated at Wadham college, Oxford, where he held a fellowship (1657-70). Having taken orders he became a prebendary of Lincoln in 1660. In the preceding year he had gained a reputation by his poem To the Happie Memory of the most Renowned Prince Oliver, Lord Protector (London, 1659), and he was afterward well known as a wit, preacher and man of letters. His chief prose works are the Observations upon Monsieur de Sorbier's Voyage into England (London, 1665), a satirical reply to the strictures on Englishmen in Samuel de Sorbière's book of that name, and a History of the Royal society of London (London, 1667), which Sprat had helped to found. In 1669 he became canon of Westminster, and in 1670 rector of Uffington, Lincolnshire. He was chaplain to Charles II in 1676, curate and lecturer at St. Margaret's, Westminster, in 1679, canon of Windsor in 1681, dean of Westminster in 1683 and bishop of Rochester in 1684. Although he opposed the motion of 1689 declaring the throne vacant, he assisted at the coronation of William and Mary. As dean of Westminster he directed Sir

gow, his consecration in London, however, not taking place until Christopher Wren's restoration of the abbey. He died on May Oct. 1610. On May 30, 1605, he became a member of the

SPRAT, a marine fish (Clupea spratus), one of the smallest species of the genus Clupea or herrings, rarely exceeds 5 in. In length, and occurs in large shoals on the Atlantic coasts of Europe. The sprat spawns in the open sea from February to May. Its eggs are buoyant and pelagic and easily recognized. The sprat is one of the more important food fishes because of the immense numbers in its shoals. In Norway large quantities are tinned in oil, or are eaten fresh, pickled, smoked or prepared as anchovies

SPRATT, THOMAS ABEL BRIMAGE (1811-1888), English vice-admiral, hydrographer and geologist, was born at. East Teignmouth on May 11, 1811. He was the eldest son of Commander James Spratt, R.N., and entered the navy in 1827. He was attached to the surveying branch, and was engaged almost continuously until 1863 in surveying the Mediterranean. As commander of the "Spitfire" he rendered distinguished service in the Black sea during the Crimean War, and was appointed C.B. in 1855. At an early date he was associated with the naturalist Edward Forbes with whom he studied the bathymetrical distribution of marine life and later published Travels in Lycia, etc. (1847). Spratt investigated the caves at Malta, studied the geology of several Greek islands and the shores of Asia Minor, and made detailed observations on the Delta of the Nile. He was especially distinguished for his Travels and Researches in Crete (2 vols., 1865), in which he described the physical geography, geology, archaeology and natural history of the island. He was commissioner of fisheries from 1866 to 1873 and acting conservator of the Mersey from 1870 until his death at Tunbridge Wells on

March 10, 1888. SPRAYING AND DUSTING MACHINERY. A great variety of equipment is available for applying certain organic and inorganic substances in solution or dust form to combat insect pests and plant diseases of field, garden and orchard crops, and to kill certain noxious weeds. Spraying is also used for thinning fruit with blossom-killing solutions, and to prevent preharvest drop of fruit.

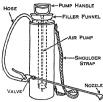

So far, experiments in the application of sprays to prevent preharvest fruit drop have shown their practicability only in the cases of apples and pears. Promising work was underway in 1944 on the use of aerosol fog spraying, which is highly toxic to a large number of insects, is not toxic to man, and is noninflammable. This method makes use of an insecticide such as pyrethrum or rotenone dissolved in a highly volatile substance such as freon (widely used as a refrigerant), the mixture or solution being contained in a steel "bomb" where a constant pressure of about 90 lb. per sq.in, is developed at summer temperatures. When released through a small nozzle the mixture comes out as a fine spray or fog. The entire output of this material was used during World War II by the U.S. armed forces for ridding tents and other quarters of flies, mosquitoes and other insects. Aeroplanes returning from tropical regions were also treated with it, as a control over the malarial and yellow fever mosquitoes.

There was promise in 1944 of hormone spraying, particularly in the case of tomatoes, to set the fruit, instead of relying on pollenizing which under some conditions is difficult. The term sprayer refers to the devices which apply solutions, and duster to those which apply dusts.

Spraying Equipment.—Sprayers utilize pressure produced by pumps to force the solution through specially designed nozales which break it up into mists. Sprayers differ in construction according to make, power by which they are operated, and type.

Accessories such as nozzles are highly important in spraying and dusting. Nozzles for spraying are of two general types; one produces a spray in the form of a cone for medium and close application, and the other produces a comparatively solid stream which breaks into a spray at a considerable height. There are, however, many variations in nozzles and most manufacturers have developed their own designs. The cone-shaped spray is often produced by forcing the liquid into a small eddy chamber of the nozzle through tangential channels in a disk. This action tends to break up the liquid just before it is forced out of the nozzle.

The solid-stream type is generally used in single units and for spraying tall trees. The cone type may be used on a single-jet gun for general purpose spraying or on a multiple-jet gun to pro-

COURTESY, U.S. DEPT. OF AGRICULTUDE

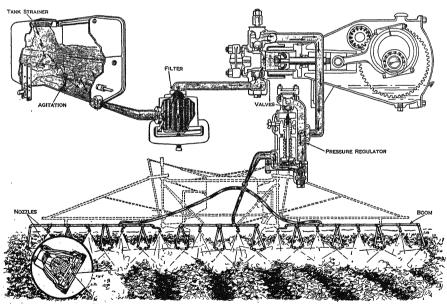

duce a foglike spray, desirable in orchard spraying. Except for the simple sprayers, the nozzles are attached singly or in multiple to a rod with cutoff for general purpose or orchard sprayers, and to adjustable pipes of booms for row crop spraying. Grape and hop growers spray with vertical pipes having nozzles fitted on the sides. Weed-killing sprays are applied from a horizontal boom with nozzles attached directly to -COMPRESSED AIR SPRAYER the under side. The solution

supply is controlled by means of suitable valves at the pump. Manual Sprayers.-The simplest form of sprayer consists of a bicycle-type hand pump with small container attached, and a suitable nozzle. In another type the hand pump, sometimes with an air chamber, is clamped to a bucket. The knapsack sprayer, as its name implies, is carried on the back of the operator, pressure usually being provided through a diaphragm pump which also actuates an agitator. In the compressed-air sprayer pressure is built up with a plunger-type air pump housed in the container with the solution and air. The one shown in fig. 1 has a capacity of from 1½ to 4 gal. Of this same type but of larger capacity are the wheelbarrow and barrel sprayers. The barrel type may either be stationary or portable.

Power Sprayers.—There are three types of power sprayers: those powered with an engine mounted on the frame with the tank, those powered through a power take-off, and those deriving their power from a traction drive. With the first two the same type of sprayer may be used. This consists essentially of a single-

acting, plunger-type, reciprocating pump (usually 2- or 3-cylinder), strainer, a pressure regulator which also acts as a safety valve, a metal or wooden tank containing the liquid and an agitator for stirring it, together with such accessories as pressure gauges, cut-off valves, and, frequently, air chambers. Such a sprayer is shown in fig 2. The pumps obtain their reciprocating motion most commonly from either a crankshaft and connecting rods, eccentric and connecting rods, or a Scotch yoke assembly (fig. 3), and are available in a wide range of sizes and capacities with pressures up to 1,000 lb. per sq in. Corrosion-resistant valve seats and ball-type valves, usually of hardened stainless steel, are used in the pumps and two types of plunger-cylinder combination; the "plunger-cup," where the cup is fastened to and moves with the plunger rubbing against the cylinder wall, which is usually coated with porcelain; and the "outside-packing" type, in which a stainless steel plunger works back and forth in the stationary packing lining the cylinder walls. The engine-powered sprayer, together with engine, may be mounted on skids for semistationary work and supplied with portable pipe lines to conduct the solution; or it may be fixed as a stationary plant and powered either with an engine or electric motor. In this case the conducting pipes are buried in the ground and lead to risers at strategic points for attachment of the spraying equipment. It may also be mounted on a motor truck or on a 2- or 4-wheel chassis and pulled by horses or a tractor.

The sprayer with power take-off may be mounted on a 2- or 4-wheel trailer and driven by a power take-off connection from the tractor pulling it, or from the transmission case of the truck transporting it. Occasionally the whole spraying outfit may be mounted on the tractor. While truck-mounted sprayers already have the advantage of pneumatic tires, and tractors are usually thus fitted, pneumatics are being increasingly used on sprayequipment trailers. An important accessory for orchard spraying is an elevated platform or tower. This permits the operator to do a better spraying job on the tops of trees and with less

COURTERY OF JOHN BELD WEG. CO.

FIG. 2.-TYPICAL POWER SPRAYER

material than from the ground. Traction-driven sprayers derive their power from the transport wheels and their use is limited largely to row crops. This type of sprayer is being replaced by the power take-off or auxiliary-engine drive.

Dusting Equipment.—Dusters for applying insecticides and fungicides make use of an air blast produced by means of a fan or plunger-type air pump, which blows the dust into a discharge

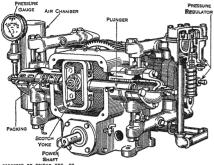

FIG. 3.—SPRAYER PUMP. CUT AWAY TO SHOW WORKING PARTS

pipe which may be fitted with a straight tube or fan-shaped nozzle. The many makes and models of dusters are of four classes: (1) hand operated, in which the air pressure is built up with a plunger pump or with a crank-operated fan; (2) the traction machine, in which the power for operating is taken from the ground wheels through chains or gears; (3) the power duster (horse or tractor drawn), operated by an auxiliary gasoline engine and suitable for

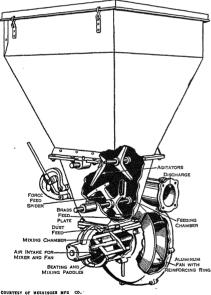

FIG. 4.-TYPICAL DUSTER

single-spout orchard dusting, or (by changing to a multiple nozzle unit) useful in row-crop dusting; and (4) the tractor-power duster mounted on the tractor and driven through the tractor power take-off. The power and traction types consist essentially of a hopper, agitator, feed control, blower fan, mixing chamber, discharge tubes and nozzle or nozzles.

Aeroplane Dusting.—In the cotton belt of the United States, as the committed of the plants by means of aeroplanes has proved economical. The work is done during daylight, generally in the early morning or late afternoons, when it is considered safest to fly at the low altitudes necessary, and when, too, the moisture on the plants causes the dust particles to adhere better. Commercial firms usually do the dusting on a per-acre basis and commonly dust at a rate of 350 or more acres of cotton per hour.

Dusting by aeroplane has also been employed in California to control insect pests and plant diseases attacking a number of fruit, nut, vegetable and small grain crops. In 1941 the acreage so treated in that state amounted to 176.600.

Experiments have shown the practicability of applying certain dusts to hasten the ripening of certain crops. In the case of cotton, such dusting causes leaves to drop and the rapid ripening of all bolls.

This facilitates mechanical picking of the fibre and permits of a once-over picking job in place of about three pickings otherwise necessary when the bolls ripen unevenly. Likewise with soybeans, if there are indications of an early frost previous to the time the crop should ripen, maturity can be hastened by the application of a defoliating dust. This procedure also causes uniform ripening of the plants.

ripening of the plants.

Steiner, Insecticides and Equipment for Controlling Insects on Fruits and Vegetables, U.S.D.A. Miscellaneous Publication No. 526 (1943); Chester N. Husman, A Hopper and Mackanism for Distribution of Batin and Dust by Airplanes for Insect Control (ET-21-U.S.D.A.-1943); E. R. McGovran, J. H. Fales and L. D. Goodhue, "Testing Aerosols Against House Flies," Soap and Sanitary Chemicals (Sept. 1943).

SPREE (sprā), a river of Prussia, 227 mi. in length, rising in Saxony, close to the Bohemian frontier, and flowing north past Bautzen, Spremberg and Kottbus, dividing between the first two towns for a time into two arms. Below Kottbus the river splits into a network of channels in the peculiar marshy region known as the Spreewald, then passes Fürstenwalde and Köpenick, threads Berlin in several arms and joins the Havel at Spandau.

More than 100 mi. of it are navigable and it is connected with neighbouring rivers by canals.

SPREEWALD, a district of Germany, in the province of Brandenburg, a marshy depression of the middle Spree valley, to sq.mi. in extent, 27 mi. long and varying from 'x to 7 mi. in width. The river Spree above Lübben splits into more than 200 arms, and in seasons of flood generally overflows considerable portions of this region.

Part of the region is cultivated, part used as pasture land and wooded like a park especially in the lower districts. Fishing, cattle breeding and the growing of vegetables, more particularly small pickling cucumbers, are the chief occupations of the people, some of whom retain their original Wendish language, customs and costumes. Spreewald is a popular summer resort of the Berlin people, and in winter is popular for skating.

SPREMBERG, a town in the Prussian province of Brandenburg, Germany, partly on an island in the river Spree and partly on the west bank, 76 mi. S.E. of Berlin by the railway to Görlitz. Pop. (1930) 14,515.

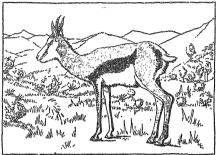

There are a pilgrimage chapel, dating from 1100 and a ducal château, built about the end of the 16th century (now utilized as government offices). Woollen cloth, bicycles, bricks and cigars are manufactured there.

**SPRING**, the act of springing, or leaping; hence applied in various senses: to the season of the year in which plant life begins

to bud and shoot; to a source of water springing or welling up from below the surface of the earth (see WATER SUPPLY); or to an elastic or resilient body or contrivance for receiving and imparting mechanical power.

In architecture, the level of the plane at which an arch or vault begins to curve inward toward the centre; in an arch or vault whose curves are circular or segments of circles, the level of the centre points from which the circular curves are described.

SPRINGBUCK or Springbok (Antidorcas marsupialis), a small South African gazelle inhabiting the country south of

BY COURTESY OF THE N Y. ZOOLOGICAL SOCIETY
SPRINGBUCK OR SPRINGBOK (ANTIDORCAS MARSUPIALIS), THE SOUTH
AFRICAN GAZELLE

the Zambezi, but ranging northwestward to Mossamedes. In the more settled parts of Cape Province, the Transval and the Orange Free State it now exists only within the enclosures of the large farms. Both sexes carry lyrate horns; the shoulder height of an adult male is about 30 in., and an average pair of horns measures 14 in. along the curve; in the female the horns are more slender. The general colour above is reddish fawn, separated from the white of the underparts by a dark band on the flanks.

SPRINGER, the term given in architecture to the stone from which an arch springs (see ARCH); in some cases this is the stone resting on the impost or capital, the upper surface of which is a plane directed to the centre of the arch.

SPRINGFIELD, the capital city of Illinois, U.S., and the county seat of Sangamon county near the Sangamon river, 99 mi. N.E. of St. Louis, Mo., and 185 mi. S.W. of Chicago, Ill. served by the Gulf, Mobile and Ohio, the Baltimore and Ohio, the Chicago and Illinois Midland, the Illinois Central, the Illinois Terminal system (electric) and the Wabash railroads; has a class IV public airport; and is at the intersection of U.S. highways 36, 66 and 54 and of state highways 4, 29 and 125. Pop. (1950) 80,832; (1940) 75,503 by federal census. The city occupies an area of 10.3 sq.mi. The state capitol (begun in 1868 and occupied since 1876) is in the form of a Latin cross, surmounted by a massive, symmetrical dome. The Illinois Centennial building, erected 1918-22 to mark the 100th anniversary of the admission of Illinois into the union, is also in the capitol group. In this building are the state historical and general libraries, the state museum, the Hall of Flags (in which are the battle flags of all Illinois regiments since Illinois became a state) and a number of state departments and offices. Facing the capitol building is the Illinois supreme court building. Adjacent to the capitol on the north is the Illinois state armoury, completed in 1936 at a cost of more than \$1,000,-000; also on the capitol grounds is the state archives building, completed in 1939, the second such state archives building to be constructed in the country. A short distance from the capitol grounds is the executive mansion, the residence of governors of Illinois, first occupied in 1856. The old capitol building, begun in 1837 and occupied from 1840 to 1876, is now used as the Sangamon county courthouse. In this building Abraham Lincoln served as a member of the legislature, and made many of his famous pre-Civil War speeches, including the "House divided against itself cannot stand" speech.

Near the centre of the business section is the Lincoln home, the only one he ever owned, which he bought two years after his mariage and occupied until he moved to Washington to assume the presidency. It is owned and maintained as a state memorial by the state of Illinois. The Lincoln tomb and monument, in Oak Ridge cemetery about 1 mi. N. of the capitol, is a granite structure 121 ft. high over the mausoleum containing the bodies of Lincoln, his wife and three of his four children, Edward Baker, William Wallace and Thomas, known as "Tad." (Lincoln's eldest son, Robert, was buried in Arlington National cemetery.) This historic structure is owned and maintained by the state of Illinois. In 1930–31, because of structural faults in the edifice, it was completely rebuilt in the original form and with the original material so far as the exterior is concerned, but with the interior redesigned.

Springfield is full of spots associated with Abraham Lincoln: so of his law offices, boardinghouses and homes of friends; courtrooms where he practised; the old statehouse, now the county courthouse, where he maintained headquarters during his campaign for the presidency in 1860 and where his body lay in state in 1865; the site of Wabash station where, on leaving for the White House, he bade goodbye to his friends in his noted farewell address; and many others. The city has nine parks containing more than 1,000 ac., and 1 mi. N. of the centre of the city are the grounds of the Illinois State fair, held annually in August. These grounds contain more than 400 ac. of land. The city is governed under the commission form of city government, adopted in 1911. The assessed value of property within the city limits for 1949 was \$209,567,856.

Springfield is in the centre of soft-coal mining fields, and several coal mines are in and adjacent to the city. The city is also the centre of a rich agricultural area with farming, stock raising and dairying. It is a large wholesale and retail centre. Among the leading industrial products are electric meters, agricultural implements, industrial tractors, road graders and road machinery, flour and cereal products, soybean oil and meal, garage and automobile equipment, house and industrial paints, ladies' shoes, miners' lamps and equipment, heavy-duty steam boiler installations, electronic equipment and mattresses.

Bank clearings in 1949 totalled \$178,172,999. The city obtains its water supply from a large artificial lake known as Lake Springfield, completed in 1935. This body of water is 15 mi. in length, with a shore line of more than 45 mi. A water treatment plant, owned and operated, as is the lake, by the city through its department of public property, affords an adequate supply of pure water. The city owns and controls more than 4,000 ac. of land bordering the lake, developed as a residential and recreational area.

Springfield was first settled in 1818–19 by trappers and hunters from North Carolina, Virginia and Kentucky. In 1823 it became the county seat and was named Springfield, no reason being discovered for the choice of its name. It was incorporated as a town in 1832, and was selected as capital of the state in 1837 in place of Vandalia. In 1840 it was chartered as a city.

Gen. U. S. Grant assumed his first command during the Civil War in Springfield when he was named Colonel in charge of a volunteer regiment on July 3, 1861. Springfield was the birth-place and lifetime home of Nicholas Vachel Lindsay, the American poet, and was the early home of Julius Rosenwald, mail-order merchant and philanthropist.

SPRINGFIELD, a city of Massachusetts, U.S., at the intersection of federal highways 5 and 20, on the east bank of the Connecticut river, 6 mi. from the southern boundary of the state; the county seat of Hampden county. It is served by the New York Central (Boston and Albany division), the Boston and Maine and the New York, New Haven and Hartford railways; several air lines also serve Springfield from Bradley field, Windsor Locks, Conn., 12 mi. from the city. Pop. (1950) 162,601; (1940) 149,554 by the federal census. The area of the city is 31.90 sq.mi. It has many buildings of architectural importance, and from 1921

its development was guided by an official planning board. The Union railroad station, opened in 1926, is one of the most commodious and complete in New England. The courthouse, two churches and other buildings were designed by H. H. Richardson. Facing a public park is the fine municipal group (designed by Pell and Corbett) which was dedicated in 1913, replacing the city hall completed during 1854 and completely destroyed by fire in 1905. The group consists of twin buildings (one an auditorium and the other an administration building, each 115 ft. wide, with a portico formed by ten Corinthian columns 41 ft. high) on either side of a campanile 300 ft. high, which contains a carillon of 12 bells. The city's parks, playgrounds and lands cover more than 2,000 ac. Forest park has an area of 754 ac. and includes a zoological section and fine collections of lotus plants. A museum (1895) contains the valuable collections of George Walter Vincent Smith, Near it is the Museum of Natural History; the city library; the William Pynchon Memorial building, home of the Connecticut Valley Historical society; and the Museum of Fine Arts, built in 1932 with funds left by Mrs. James Philip Gray. In Merrick park, adjoining the library, stands Augustus Saint-Gaudens' statue of "The Puritan." The city has its own symphony orchestra,

The public-school system includes commercial, technical, trade and classical high schools. The American International college (1885) and Springfield college (the International Young Men's Christian Association college, 1885) are in Springfield. There are 90 churches in the city, and it is the see of a Roman Catholic and a Protestant Episcopal bishop. The city operates under a bicameral form of government. The assessed valuation for 1949

was \$281,477,400.

There has been a U.S. arsenal in Springfield since the American Revolution, when it was established by the continental congress. and an armoury since 1794, when congress authorized the building of one of the government's first gun factories on a hill (near the present railroad station) which had been selected by Washington for the purpose in 1789. More than 800,000 of the famous Springfield muskets were made there during the Civil War. It later became the home of the famous Springfield rifle and the Garand rifle and a principal manufactory of small arms for the U.S. army. The Smith and Wesson revolver factory is located there. Other important manufactures include electrical products, matches, chemicals, valves, machinery, automotive products, leather goods, aluminum and bronze products, plastics, clothing and paper products. G. & C. Merriam company, publishers of Merriam-Webster dictionaries from 1843, has its headquarters in Springfield. The city's trade area has a population of approximately 670,000. Three insurance companies-Massachusetts Mutual Life Insurance company, Springfield Fire and Marine Insurance company and Monarch Life Insurance company—have their home offices in Springfield. Bank clearings in 1949 for the city amounted to \$399,990,902. Springfield is headquarters for the Farm Credit administration for district no. 1 which includes the Federal Land bank, Federal Intermediate Credit bank, Production Credit bank and the Springfield Bank for Cooperatives. Organization of a regional co-operative purchasing association known as Eastern States Farmers' Exchange, Inc., with headquarters in West Springfield, occurred there in 1918, and by midcentury it was serving approximately 100,000 farms in nine states. Through it farmers were buying about \$80,000,000 of feed, fertilizer, seed and other supplies annually. Also in West Springfield are the Eastern States exposition grounds, where an annual exposition is held in September. On the grounds is Storrowton, a New England colonial village given by Mrs. James J. Storrow of

Springfield was founded in 1636 by a group of settlers from Roxbury under the leadership of William Pynchon (1590?-1662), one of the original patentees of the Massachusetts Bay Colony, who left Roxbury because of increased opportunities for fur trading in the Connecticut river valley. The town was incorporated in 1642 and named after Pynchon's birthplace in Essex, Eng. For several years he ruled it with the power of an autocrat, but in 1652 he was removed from the magistracy, in consequence of a tract in which he attacked the Calvinistic doctrine of the Atonement, and

returned to England.

In King Philip's War Springfield was a centre of hostilities. After the establishment of the arsenal in 1777 it was an important military supply depot of the continental army. During Shays's Rebellion, a riot took place in Sept. 1786, and on Jan. 25, 1787, the insurgents, led by Shays, attacked the arsenal, but were dispersed by the militia. Industrial development began with the establishment of the government armoury (1794), which brought in skilled workmen and attracted other enterprises. In nine years the population increased 50%. A second impetus was given by the completion in 1839 of what later became a part of the Boston and Albany railroad. By 1850 the town had a population of 11,766 and in 1842 it was chartered as a city.

SPRINGFIELD, a city of southwestern Missouri, U.S., 185 ni. S.E. of Kansas City; the county seat of Greene county. It is on federal highways 60, 65, 66, 160 and 166; has a municipal airport; and is served by the Frisco and the Missouri Pacific railways. Pop. (1950) 66,302; (1940) 61,238; and (1930) 57,527. The city has a beautiful location on the crest of the Ozark plateau, 1,300 ft. above sea level, and is surrounded by charming scenery. The region is rich in timber, and is known for its poultry, egg production, cheese output and fruit. The creameries of Springfield handle dairy products totalling \$40,000,000 annually. Beef cattle and hogs are factors in the \$22,00,000 annual business of the stockyards. Annual sales of retail stores total approximately \$500,000,000.000. The annual pay roll of the Frisco railroad is in excess of \$9,000,000.

Springfield is the seat of Drury college (1873), the Southwest Missouri State college (1906) and Central Bible institute and seminary. Adjoining each other are a national and a Confederate

cemetery

Springfield was founded about 1829; laid out in 1833; incorpoincorpolated as a town in 1838 and again in 1846; and chartered as a city in 1847. It has a commission form of government. At the opening of the Civil War Springfield was an important strategic point. It was occupied alternately by Confederate and Union Forces until the spring of 1862, after which the Unionists retained control. The battle of Wilson's creek (Aug. 10, 1861), 10 mi. S. of the city, was one of the bloodiest engagements of the war. The first railroad reached the city in 1870.

SPRINGFIELD, a city of Ohio, U.S., the county seat of Clark county; 45 mi. W.S.W. of Columbus, on Lagonda creek, near the Mad river. It is on federal highway 40, and is served by the Big Four, the Detroit, Toledo and Ironton, the Eric and the Pennsylvania railways, by Trans World Airline, and by motorbus and truck lines. Pop. (1950) 78,029; in 1940 it was 70,662 (12% Negroes). The city occupies 13,12 sq.mi. of undulating land, reaching an allitude of 990,27 ft.

On hills north of the creek is Wittenberg college (coeducational; founded 1845). Immediately west of the college campus is

beautiful Ferncliff cemetery.

There is a large municipally owned hospital and the private Mercy hospital. A 268-ac. municipal park affords recreational facilities, and there is Clark County fairgrounds. The city has a full-sized symphony orchestra, amateur theatrical groups giving winter schedules of plays and frequent appearances of travelling theatricals.

Industrial production in Springfield is highly diversified. Chemicals, caskets, dresses, awnings, machine tools, production machinery, road building machinery, motors and thermometers are among the principal products. In 1914 Springfield adopted a commission-manager form of government. In 1799 Simon Kenton and a small party from Kentucky built a fort and 14 cabins 3 or 4 mi. W. of Springfield's present limits. Later in the year James Demint settled on a hill overlooking Lagonda creek. In 1801 he engaged a surveyor to plat a town there, and soon after this Kenton's settlement was abandoned. Trouble from the Indians threatened the new town until 1807, when peace was more firmly established at a council held on a neighbouring hill, where Tecumseh was the principal speaker. In 1818, when Clark county was established, Springfield was made the county seat. It was incorporated as a town in 1828, and in 1850, when

the population was 5,108, was chartered as a city.

SPRINGFIELD, a city in Lane county, west central Oregon, U.S.A., on the east bank of the Willamette river, with an altitude of 456 ft. It is on U.S. highways 28 and 99£, about 4 mi. E. of Eugene, and is served by the Southern Pacific railroad. The population was 10,807 in 1950 and 3,805 by the census of 1940, of whom 3,687 were native white. The chief industry is lumbering (fir), and there is a large plywood mill. Kraft paper, wax from bark, and wood sugar from the waste materials of fir are also produced. Diversified farming is carried on. Springfield, which was classified as an urban community in 1940, was incorporated in 1888.

SPRINGFIELD, the county seat of Robertson county, in northern Tennessee, U.S. It is 28 mi. N.W. of Nashville at the fork of Carr's creek and a branch of the Red river, with an altitude of 595 ft. and an area of 1.1 sq.mi. It is on U.S. highway 41E and is served by the Louisville and Nashville railroad. The population was 6,506 in 1950 and 6,668 in 1940 (4,790 native white and 1,867 Negro). As an important market for loose-leaf tobacco, the town has numerous warehouses for tobacco storage. The active trading season lasts from January through June or July. The chief industry is the manufacture of woollen blankets. Other products include chairs, flour, feed, liquid fertilizer and dairy products. Farming is diversified and includes the raising of tobacco, corn, wheat and livestock. Springfield owns and operates its electric distribution system, sewage treatment plant and waterworks. Administration is by a commission-mayor form of government through direct nonpartisan election.

Springfield was incorporated as a town in 1819. A general hospital, owned and managed by the county, was established there in

1934.

SPRINGFIELD, a town with a village by the same name, on the Connecticut river, in Windsor county, Vt., U.S., through which the Black river flows with a picturesque falls near the centre of the village. It is served for freight by an electric line connecting with the Boston and Maine railroad. Pop. (1950) town, 9,190; village, 4,940. It is a machine-tool manufacturing village with a large agricultural area. It was chartered in 1761 and has the town-manager form of government, adopted in 1920, the first town in Vermont to adopt the system.

SPRING-GUN, a device formerly in use against poachers and trespassers. Since 1827 spring-guns and all man-traps are illegal in England, except as a protection against burglars.

SPRING-RICE, SIR CECIL ARTHUR (1859-1918), British diplomatist, was born in London on Feb. 27, 1859, the second son of the Hon. Charles Spring-Rice (1819-70), and grandson of the 1st Baron Monteagle. Educated at Eton and Balliol college, Oxford, he entered the foreign office in 1882, becoming private secretary to Lord Granville in 1884 and précis writer to Lord Rosebery in 1885. He went to Washington as third secretary in 1886, and in 1895 proceeded to Berlin. In 1898 he became secretary at Teheran, and in 1901 British commissioner on the Caisse de la Dette in Cairo. In 1903 he went to St. Petersburg (Leningrad), first as secretary and later as councillor of embassy, remaining in Russia till the end of 1905. In 1906 he was sent to Persia as minister, having lately been created K.C.M.G. In 1908 he was created G.C.V.O. and went to Sweden as minister. and in 1912 was appointed ambassador to the United States. He died at Ottawa on his way home to England, Feb. 14, 1918. See Sir v. Chirol, Cecil Spring-Rice: In Memoriam (1919); Stephen Gwynn, ed., The Letters of Sir Cecil Spring-Rice (1929).

SPRINGS are, in almost all cases, the natural overflow or point of escape from some underground reservoir of water. Their classification may be either according to the geological conditions governing the point of location, or according to the chemical composition of its waters. When considerable chemical impurity is present they are usually termed "mineral springs."

The rocks which constitute the crust of the earth are either permeable or impermeable to water. During most seasons of the year, in temperate climates, a certain amount of rainfall soaks into any crust formed of permeable strata; the part absorbed may be the complete rainfall during winter months, when the

air is saturated with moisture, or may fall to near zero during a dry summer, when all the rainfall is returned to the air as evaporation from the surface. That portion of the rainfall which soaks down below the level of plant roots goes to replenish the underground reservoir. The shape of the reservoir varies indefinitely, according to the geological structure of the area; but it is only the shape of its water surface that concerns springs. This surface, known as the water table, divides the fully saturated rocks from those which only hold moisture in their minute pores,

In an area of completely permeable rocks the springs issue at or near the valley bottoms; when, however, the district is made of alternating permeable and impermeable beds, each impermeable bed holds up water on its surface. If the strata are horizontal, small springs may be found all round the outcrops; but if they are tilted or folded the flow of the underground water will be towards the lowest point on the base of the permeable water-bearing bed. At this point the main spring for that local reservoir will be located.

In strata which are, in the main, impermeable, but somewhat brittle the presence of joints and cracks is of prime importance in determining the direction and amount of flow in the underground waters. In jointed rocks the rain water may sink to great depths down one set of joints and rise again along a second, issuing at the surface as a warm or thermal spring; this is the probable cause of the hot springs at Bath. When a permeable bed and an impermeable one are brought into juxtaposition through faulting the flow of water in the permeable one is checked; but since faulting frequently shatters the rock it affords a plane of weakness along which the water will tend to flow. If the water is flowing under pressure due to an overlying impermeable cover, it may reach the surface as an "artesian spring." The water of artesian springs sometimes carries small particles of solid matter in suspension as well as salts in solution. The solid particles are dropped at the point of exit of the spring and may be cemented by the salts deposited from solution. When this takes place a mound is built up, from the summit of which the spring issues. Hence the "mound springs," such as are seen at their best in the great artesian basin of Australia.

Some of the largest springs issue from thick beds of massive limestone. This type of rock is usually well jointed and, being soluble in rain water, the joints and marked bedding planes become enlarged by solution and the whole of the rainfall is absorbed in the mass of the rock and flows underground to issue as large springs. Frequently these springs yield a somewhat hard water of otherwise great purity.

Mineral Springs.—All springs containing noticeable quantities of salts in solution, other than the carbonate and sulphate of lime, are known by this name. The commonest minerals found are common salt, giving rise to "bitter springs"; and iron, sulphur, magnesia, etc., giving "medicinal" waters.

Thermal Springs.—The springs coming under this heading are derived from two sources. Firstly, meteoric waters which have penetrated down to considerable depths and rise again along well-defined fissures issuing as springs at the surface, but with the temperature of the rocks from which they have come; and, see ondly, volcanic waters, either in the form of geysers or hot springs (see Volcano); in these the water may be either meteoric or in part, at any rate, juvenile—that is, water which is issuing at the surface for the first time. Most of these waters contain much mineral substance in solution, which is deposited on cooling and forms marked basins and terraces of sinter, such as the famous pink and white terraces of New Zealand.

(W. B. R. K.)

SPRINGTAIL, any one of the small wingless insects of the order Collembola, so-called because many of them possess a pair of tail-like abdominal appendages adapted for springing. They are widely distributed in the world, and are abundant in the soil and in decaying vegetation. Springtails lay small almost spherical eggs. The newly hatched young are, except for their small size, very similar to the adults. The food of springtails consists largely of decaying bits of vegetation. Some species, however, feed on the tender tissues of growing plants and are of consid-

erable economic importance. (See also APTERYGOTA ) (H. E. E.)

SPRING VALLEY, a city of Bureau county, Illinois, U.S.A., on the north bank of the Illinois river, 104 mi. S.W. of Chicago. It is served by the Burlington Route, the Chicago and North Western and the Rock Island railways. Pop. 4,916 in 1950; in 1940 it was 5,010. It is a shipping point for coal, zinc, cement and farm products. The city was founded in 1885 and chartered in 1886.

SPRINKLERS, AUTOMATIC. These are a means of combating fire which has the approval of fire insurance companies, who often make a reduction in their premiums when it is employed. The essence of the device is to arrange, under the ceiling of the building to be protected, a series of sprinklers which discharge water as soon as the temperature reaches a certain point. The automatic release of the water is contrived by closing the valves of the sprinklers with fusible metal; the alloy employed being such as to fuse at a temperature of say 150° F. The sprinkler is so devised that the jet spreads the water in a shower, and the distance between the sprinklers is so arranged that every part of the floor is covered. The sprinklers are connected with lines of pipes conveying the water under pressure. In buildings where the water-pipes are likely to freeze, the ceiling connections are filled with air under pressure, so that when the valve opens through the metal fusing, the air escapes and the loss of pressure in the pipes works a lever that opens the valve of the water main. (See also FIRE PROTECTION.)

SPRUCE (Picea), an important genus of evergreen coniferous trees of the pine family (Pinaceae), called also spruce fir, includ-

ing about 40 species, natives of the cold and temperate regions of the northern hemisphere. They are pyramidal trees, with whorled branches; thin, scaly bark; linear, spirally-arranged leaves, each jointed near the stem on a separate woody base; and ovoid, oblong or cylindrical spreading cones, which become pendent when mature. The spruces are readily distinguished from the pines by their solitary instead of fascicled leaves, which leave peglike projections on the twig when they fall, and from the firs in having pendent cones with persistent scales instead of upright cones with deciduous scales.

In an economic sense the most valuable species is the Norway spruce (P. excelsa), native to

BRANCH OF THE NORWAY SPRUCE (PICEA EXCELSA) BEARING CONES Small figure shows single scale with two winged seeds

northern Europe and Asia and well known in plantations in the British Isles and eastern North America, though hardly attaining in cultivation the great height and noble form which it displays in its native woods. In favourable situations it becomes the tallest and one of the stateliest of European trees, sometimes rising to a height of 170 ft, and attaining a trunk diameter of 5 to 6 ft. at the base. It has a nearly straight, tapering trunk, throwing out in somewhat irregular whorls its widespreading branches densely clothed with dark clear green foliage. The boughs and their side branches, as they increase in length, have a tendency to droop, the lower tier, even in large trees, often sweeping the ground, a habit that gives a peculiarly picturesque effect. The slender, sharp, slightly curved leaves are scattered thickly around the shoots; the upper ones pressed toward the stem, and the lower directed sideways, giving a somewhat flattened appearance to the individual sprays. The cylindrical cones, 4 to 7 in. long, grow chiefly at the ends of the upper branches.

The Norway spruce is very widely distributed, growing on most of the mountain ranges of Europe from the Pyrenees northward and extending to 68° N., while in Asai it extends eastward to the Lena river and from the Altai mountains to beyond the Arctic circle. On the Swiss Alps it is one of the most prevalent and 21—K

striking of the forest trees. In the lower districts of Sweden it is the predominant tree in most of the great forests; in Norway it constitutes a considerable part of the dense woods of the southern valleys, flourishing on mountain slopes up to 3,000 ft. and clothing the shores of some of the fjords to the water's edge

While less valuable than the pine, the Norway spruce is an important timber tree. When produced in close forests the white wood is of compact and even grain and suitable for a great variety of uses. Immense quantities of spruce lumber are imported into Great Britain from northwestern Europe. Great quantities also of younger trees are imported as poles, used for scaffolding, ladders and mining timber. In Norway the wood is very extensively made by hydroelectric power into wood pulp.

As an ornamental tree Norway spruce has been commonly planted in Great Britain since about 1600. It is also grown as a "murse" for other trees, for shelter for wall fruit, for cover for game, and for small stakes and poles. As a picturesque tree for park and other ornamental plantation it ranks among the best of the conifers, bearing the smoke of cities better than most of the fir group, though subject to blight, which gives it an unhealthy appearance after a certain age. In North America the Norway soruce is extensively oblated in the eastern states and Canada.

In North America there are seven native species of spruce; of these, three are found in the eastern United States and Canada, two occur in the Rocky Mountain region and two are confined to the Pacific coast. The white spruce (P. glauca) is found from Maine to Minnesota northward to Labrador and Hudson bay and northwestward to Bering strait in Alaska. It grows to a height of 150 ft. and a trunk diameter of 4 ft., with cylindrical cones 2 in. long. The white spruce is very valuable for lumber and especially for wood pulp, being the chief species utilized in the Canadian wood pulp industry. The red spruce (P. rubens) occurs from Nova Scotia to New York and southward in the mountains to Tennessee. It is the dominant spruce in the Adirondack region, attaining a height of 60 to 100 ft., with brownish-red ovoid cones, about 11 in. long; it is extensively used for lumber and pulp wood. The black or bog spruce (P. mariana), native to swamps from Newfoundland to Alaska and southward to Virginia and Minnesota, commonly 20 to 30 ft. but sometimes 90 ft. high, with small globose cones, is utilized for pulp wood and is the source of spruce gum.

The Engelmann spruce (P. engelmanni), native to the Rocky Mountain region and extending westward to British Columbia and California, is a handsome tree of high altitudes. It grows from 20 to 150 ft. high, with slender branches and oval cones, sometimes 3 in. long. The blue or Colorado spruce (P. pungens), native to the central Rocky Mountain region, is one of the most distinctive American species. It grows from 80 to 150 ft. high, with stiff, horizontal branches, and rigid, bluish-green to silverwhite, spiny-tipped leaves, and oblong cones, 2½ to 4 in. long. Several varieties with characteristically blue foliage, as the well-known Koster blue spruce (var. kosteriana) are widely grown for ornament.

The Sitka or tideland spruce (P. sitchensis) occurs along the Pacific, extending about 50 mi. inland, from Kodiak island, Alaska, southward to northern California. It is the most massive of the spruces, sometimes attaining a height of 790 ft. and a basal trunk diameter of 20 ft., but it usually grows about 100 ft. high, with a trunk 3 ft. in diameter, with widely spreading, rigid branches, stiff, usually prickly-pointed leaves, and oblong cones 2 to 4 in. in length. The Sitka spruce is a valuable timber tree, and is extensively lumbered. The rare weeping spruce (P. breweriana), with hanging branches clothing the trunk to the ground and with the few horizontal branches decorated with cordlike hanging branchelets, is confined to the coastal mountains of northern California and adjacent Oregon.

Among the various old world spruces planted as ornamental trees are the Serbian spruce (*P. omorika*); the oriental spruce (*P. orientalis*), of Asia Minor; the Himalayan spruce (*P. smithiana*), the Alcock spruce (*P. bicolor*) and the tiger-tail spruce (*P. polita*), natives of Japan.

SPRUE. Sprue is a disease of tropical and subtropical regions,

and possibly cases arise in temperate climates also.

Symptoms.-The symptoms usually begin with dyspepsia and irregularity of bowel action. In a fully declared case the chief signs are the passage of bulky, frothy, pale porridge-like, stools, much flatulence and acidity, a sore, ulcerated mouth, a red, smooth and tender tongue, often with exquisitely painful ulcers on the fraenum and at the sides. Loss of flesh is very rapid amounting perhaps to 40 lb. in two months. Cramps of the fingers and of the feet and calves are common in severe cases. Death occurs from exhaustion and intercurrent disease or, more usually, from intense anaemia, or rarely from perforation of an intestinal ulcer.

Treatment.-The treatment is rest in bed for a fortnight on a diet restricted to milk (increasing from 4 to 71 pints daily) together with calcium lactate (gr. 15 thrice daily) and extract of parathyroid (gr. 1/10th twice daily). The parathyroid must be free from admixture with thyroid (most preparations contain some of the latter) for if any of the latter be present, the symptoms become aggravated and palpitation and other indications of thyroid excess are superadded. With a pure preparation, however, the sprue symptoms improve within a fortnight, the ionic calcium increases to about 8 mg. %, the stools are reduced to one a day and the soreness of the mouth disappears. At the end of four weeks in favourable cases, the calcium lactate can be dropped and the parathyroid reduced to half doses. About this time the blood serum will show a normal calcium content, but the parathyroid extract should not be left off entirely for another three to four weeks. Should symptoms recur, a return for a few days to a simpler diet and to the parathyroid extract will restore health.

Many patients treated on these lines have returned to their duties abroad, many others have been treated in the tropics and have recovered. A few years ago the appearance of sprue meant immediate return to a temperate climate and prohibition of future residence in the tronics. (H. H. S.)

SPUR, an instrument attached to the heel of a rider's boot for the purpose of goading the horse. (A.S. spura, spora, related to spornan, spurnan, to kick, spurn.) The earliest form of the horseman's spur armed the heel with a single prick. In England the rowel spur is shown upon the first seal of Henry III, but it did not come into general use until the 14th century. In the 15th century spurs appear with very long shanks, to reach the horse's flank below the outstanding bards. After this time, and until the Restoration, they take many decorative forms, some of which remain in the great spurs worn by Mexican cavaliers. Gilded spurs were reckoned the badge of knighthood, and in the rare cases of ceremonial degradation they were hacked from the knight's heels by the cook's chopper.

In architecture, a spur (Fr. griffe, Ger. Knoll), is the ornament carved on the angles of the base of early columns; it consists of a projecting claw, which, emerging from the lower torus of the base, rests on the projecting angle of the square plinth; the earliest known example is in Diocletian's palace at Split (Spalato). In Romanesque work the oldest examples are those found on the bases in crypts, where they assumed various conventional forms; being, however, close to the eye, the spur soon developed into an elaborate leaf ornament, which in French 13th-century work and in the early English period is of great beauty.

SPURGE, a name applied to plants known botanically as Euphorbia (q.v.). The spurge-flax is Daphne gnidium, and the spurge-laurel Daphne laureola, both found in Great Britain.

SPURGEON, CHARLES HADDON (1834-1892), English Nonconformist divine, was born at Kelvedon, Essex, on June 19, 1834. In 1852 he became pastor of Waterbeach. His powers as a boy preacher became widely known, and at the close of 1853 he was "called" to New Park Street chapel, Southwark. Exeter hall was used while a new chapel was being erected, but even that could not contain Spurgeon's hearers. The enlarged chapel at once proved too small for the crowds, and a huge taber-

nacle was projected in Newington causeway. The Tabernacle was opened for service on March 25, 1861. Spurgeon preached at the Tabernacle on Sundays and Thursdays.

His Sunday sermons were sold literally by tons. They are models of Puritan exposition and of appeal through the emotions to the individual conscience, illuminated by frequent flashes of spontaneous and often highly unconventional humour. Collected as The Tabernacle Pulpit, the sermons form some 50 volumes. His book of savings called John Ploughman's Talks; or, Plain Advice for Plain People (1869) found many readers. In 1887 his distrust of modern Biblical criticism led to his withdrawing from the Baptist union. He died at Mentone on Jan. 31, 1892.

See the Life by Schindler (1892) and Spurgeon's Autobiography, compiled by his widow and his private secretary from his diary sermons, records and letters (1897-1900).

SPURN HEAD, foreland of the North sea coast of Yorkshire, England, projecting across the mouth of the Humber. From Kilnsea it is 4 mi. long but seldom exceeds 300 yd. wide. Formed of sand and shingle from the rapidly denuding Holderness coast to the north, it is only a few feet above sea level.

SPY, a commune near Namur, Belgium. Pop. (1939) 3,243. Here in 1886, in Betche aux Roches cavern, Maximin Lohest and Marcel de Puydt found two nearly perfect skeletons (man and woman) at the depth of 16 ft., with numerous implements of the early Aurignacian period. All the human remains are in the Lohest collection, Liége. The skulls are of the Neanderthal type.

See L'Homme Contemporain du Mammouth à Spy (Namur, 1887); G. de Mortillet, Le Préhistorique (1900); Sir A. Keith, Antiquity of Man, 2nd ed. (1925).

SPY: see LAWS OF WAR.

SQUADRON, (1) a military term referring to the subdivision of a cavalry regiment, (2) a naval term referring to a detachment of war vessels, and (3) an air force term denoting a unit of a "group." Literally the term means a body of fighting men formed into a square. In 1656 the term was appropriated by horsemen but even in 1810 Scott in The Lady of the Lake refers to "squadrons tramping." The earliest use of the word in the military sense appears to be in 1562 and in 1581 Styward in Martial Discipline gives a clue to its origin: "The poore Swizers not being able to furnishe themselves with horse, were the first devisers of the pike and the squadrone," from which it is inferred that a body of pikemen formed into a square were employed on the flanks of a formation. This appears to be confirmed by Bullokar who wrote in 1616 that a squadron was a "square form in a battel." Previous to this, Sir John Smyth in 1500 refers to squadrons in reference to infantry, as also does Ward as late as

Morvson in 1617 mentions "two squadrons of foot 250 men each." In 1702 a squadron of horse was anything between 100 and 200 men but by 1779 the number had been reduced to 80-120. At that date the squadron was composed of three complete troops.

The Cavalry Regulations (British) of 1832 state that "Two or more squadrons compose a regiment." In the modern military sense a squadron is one of the principal units into which a regiment of cavalry is divided, corresponding to a company of infantry, the normal being three or four squadrons, subdivided into "troops." Squadrons are usually between 120 and 200 men. (See CAVALRY.)

In the naval sense the term refers to a part of a fleet usually commanded by a flag officer, or it may be applied loosely to any number of vessels less than a whole fleet. For its application to the air force see AIR WARFARE.

In British military use, "squad" (a shortened form of "squadron") is used of any small detachment of men temporarily formed for drill or fatigue work or other duty. In the U.S. army, however, the squad is the basic infantry unit.

SQUALL, the name given to any sudden large increase of wind velocity of less transient character than a "gust." A squall, usually lasting for some minutes at least, is attributable to meteorological causes, while gusts, which may succeed one another every few seconds, are the result of some mechanical interference with the direct flow of air and are thus produced by turbulence. A squall may include a succession of gusts.

It is difficult to give exact figures for the actual force of the wind during gusts, but 106.5 m.p.h. were recorded at Pendennis castle on March 14, 1905; and 231 m.p.h. on Mt. Washington, New Hampshire, April 12, 1934. Squalls with velocities reaching 55 m.p.h. are not uncommon, and the range of wind velocity during gusts in such a squall may be anything between 40 m.p.h. and upwards of 100 m.p.h.

A squall may be either a rotary wind covering a small area (sometimes called a bull's eye squall) or a straightaway wind. The latter type frequently accompanies the onset of a thunderstorm; as the storm approaches, the wind dies down, then blows gently toward the storm; finally, as the rain is almost at hand, a violent gusty wind abruptly sets in, blowing directly outward from the storm and usually lasting for only a short time. At many places on the earth, local conditions result in the frequent occurrence of squalls of characteristic types, which are called by local names; e.g., the "williwaws" common on many steep coasts in high latitudes, caused by a brief violent drainage of cold air down the steep slopes.

These phenomena are best exhibited in "line squalls." As the name suggests, a number of places arranged, roughly, in a continuous line, often hundreds of miles long, experience simultaneously a similar sequence of events. The course of events in typical line squalls has been worked out by R. G. K. Lempfert and Richard Corless.

The violent winds may be attributed to the breakdown of the dynamical system under the stress of these local but sharp differences of pressure. A line squall commonly marks the "Gold front" of an extratropical cyclonic storm; to the rear of the storm, a cold air current is advancing against warmer air, and undercutting the latter.

The boundary between these two air masses is called a cold front; it is the familiar wind-shift line, along which the direction of the wind undergoes a rapid and often considerable change—e.g., from southwest to northwest—usually accompanied by a sharp drop in temperature, an abrupt increase in pressure and a break in the direction of the isobars.

This line has long been known as the squall line, because all along it sudden gusts, squalls and, in summer, thunderstorms, are very common owing to the vigorous ascent of warm air initiated by the lifting caused by the underrunning cold air. (See Giblett, "Line Squalls," Journal of the Royal Aeronautical Society, vol. 198, 1927.)

In this respect a V-shaped depression may be regarded as a special case of a line squall in which the two currents are from approximately opposite directions, and the line of the trough which sweeps forward, keeping parallel to itself, represents the linear front.

An example of a violent and destructive form of line squall is shown in the records for June 1, 1908. The Kew squall of wind which destroyed a number of the trees of Bushey avenue maintained its violence for a considerable period. Many other famous line squalls, such as those of Feb. 19, 1907, 0ct. 14, 1909, etc., have been examined. (See Lempfert and Corless, "Line Squalls and Associated Phenomena," QJ.R. Met. Soc., vol. xxxvi, 1910.) One of historic interest caused the loss of H.M.S. "Eurydice" off the Isle of Wight on March 24, 1878.

It was among the first to receive special attention and was discussed by Abercromby in 1884 (Quart. Journ. Roy. Met. Soc., x, 172) and previously by Clement Ley (Symon's Met. Mag.,

SQUARE, a term variously used in mathematics, in technical work and metaphorically. In geometry it designates a rectilinear figure having four equal sides and four equal angles, the angles being right angles. Such a figure is a special kind of rectangle cquilateral) and of parallelogram (equilateral and equiangular). It has four axes of symmetry, and its two finite diagonals (as in the case of any rectangle) are equal. If the side is s, the area is  $s \times s$ , or  $s^2$ , the name  $s^2 \times s$ , or  $s^2$ , the mane  $s^2 \times s$ , or  $s^2$ , the mane  $s^2 \times s$ , or  $s^2$ 

the side of a square its latus (side), and hence the square root of a number was often called the latus. In technical work the word is applied to instruments used for drawing or testing right angles, as in the T-square here shown and the familiar carpenter's square.

SQUASH is the fruit of Cucurbita maxima and certain varieties of C. pepo. (See Pumpern.) Summer squash is a quick-growing, small-fruited, non-trailing or bush type of C. pepo. The plants are upright-spreading, 1½ to 2½ ft. high and produce a remarkable diversity of fruit forms, ranging from flattened through oblong to elongate and crooked.

Colours range from white through cream to yellow, also green and variegated. The fruit surfaces or contours may be scalloped, smooth, ridged or warty. The fruits develop very rapidly and must be harvested only a few days after they form, before the seeds and rinds harden. They must be used soon after harvest. The entire fruit is usually cut into pieces, boiled and served with butter. The bush forms are grown about 2 ft. apart in rows 3 to 4 ft. apart. To obtain early yields, seedlings are often started in pots in frames or greenhouses and transplanted into the field after 3 or 4 leaves have developed and after danger of frost is

Winter varieties of squash, C. maxima, are long-vining, generally large-fruited, long-season kinds, that can be stored many months if kept dry and well above freezing. The fruit stems are greatly enlarged next to the fruits and the fruits show a wide range of sizes, shapes and colours. They are higher in nutritive value than summer squash or so-called pumpkins, and are cormonly baked or made into pies. They are extensively grown in the United States in home gardens, market gardens, and on a large field scale for canning. (V. R. B.)

SQUASH RACKETS. A game played on exactly the same principle as rackets but in a smaller court and with a ball made of india-rubber. The rules are in most particulars similar to rackets but the scoring is different. In matches in England, hand-in only can win an ace. The rubber is the best of five games of 9 up. If, however, the score becomes 8 all, the player who reached 8 first has the option of a set to two. In America a game consists of 15 points up, and an ace is scored for each rally irrespective of which player is serving, all matches being the best three out of five games. The rotation of service in England is just as in rackets. In the American game, the winner of one rally serves in the next.

The Court and Implements.—Squash rackets can be played in courts of many sizes and descriptions, both covered and uncovered, with three or four walls and made of concrete or wood. The first standardization of a court in England was made by the Tennis and Rackets association in 1911. Shortly after World War I the association issued revised standard dimensions, and the great majority of British courts have been built to these dimensions since. The standard court has four walls and can either be covered or uncovered. In length it is 32 ft. and in breadth 21 ft. The front and side walls are 15 ft. in height and the back wall is 7 ft. in height.

The floor in a closed court should be made of wood; in an open court, of cement. In a closed court the front wall should be of composition.

The markings on the floor and front wall of the court are exactly similar to those in a racket court. On the front wall, the top of the play line is 19 in. from the floor and the service line is 6 ft. from the floor. The short line is 14 ft. from the back wall. The service boxes are 5 ft. 3 in. square. In the space between the play-line and the floor is generally placed a strip of tin or some other metal in order to differentiate clearly in sound when the part of the front wall "in play" or "out of play" is hit. The lines on the wall and floor are painted red. Maple is considered a most suitable wood for the floor. The courts should be lighted from the roof, and nearly all modern courts, in addition to this lighting, are fitted with electric light for evening play.

The American standard court is of different size from the English,

being considerably narrower, 31 ft. by 18 ft. 6 in. The racket is precisely similar to the implement used in the game of rackets, only shorter in the handle. The ball is of black rubber. Many different forms of ball have been tried and formerly, when there

were no standard courts, the ball which seemed best suited to the particular conditions was generally used. For the present standard English court the association has adopted three standard balls. The ball used in America is larger than that in England.

Open competitions at squash rackets were unknown in England before the World War. In the years since, several have been started, the most important being the London inter-club tournament (teams of three) for the Bath Club cup; the amateur championship, the royal navy and army championships, and the ladies championships. The winners of the amateur championship were.—April 1923, Capt. T. O. Jameson; Dec. 1923, Capt Jameson; Dec. 1924, W. D. Macpherson; Jan. 1926, Capt. V. A. Cazalet; Dec. 1926, Capt. J. E. Tomkinson; Dec. 1927, Capt. V. A. Cazalet; Dec. 1928, W. D. Macpherson; 1929 and '30, Capt. V. A. Caza- ENGLISH, BENT ASH let; 1931-33 and 1935-38, F. D. Amr FRAME, SQUASH RACKET Bey; 1934, C. P. Hamilton; 1939, K. C. Gandar-Dower.

The amateur championships are held annually in December at the Bath club. The duke of Windsor is a very keen player and, as prince of Wales, competed several times in the amateur and

army championships.

The British professional champion in 1939 was J. Dear (Prince's club) who defeated D. Butcher (St. John's Wood club) in 1937. Leading lady players were Miss Cicely Fenwick, Miss Nancy Cave, Miss Joyce Cave, Miss S. Huntsman, Miss Susan Noel and Miss Margot Lumb, champion from 1936-39. F. D. Amr Bey, an Egyptian, created a sensation in London in the early '30s and was invincible against the best amateurs and, professionals for some years.

The development of the game in America was even more rapid than in England, achieving a big vogue in the late '20s and '30s. The large cities of the United States, particularly New York, Boston and Philadelphia, are amply supplied with courts; and the game is also played with much keenness in Canada. British teams visited America after 1924, the late Captain V. A. Cazalet, M. P., leading one of them, and United States teams also toured in England. Among the leading amateur champions were Stanley W. Pearson, 1915-17 and 1921-23; W. Palmer Dixon, 1925-26; Myles P. Baker, 1927; Herbert N. Rawlins Jr., 1928 and 1930; Dr. J. Lawrence Pool, 1929 and 1931; Beekman Pool, 1932-33; Neil J. Sullivan, 1934; Donald Strachan, 1935 and 1939; Germain Glidden, 1936-38; A. Willing Patterson, 1940; Charles Brinton, 1941-42.

The French Squash Rackets association was formed in 1926 and four courts were opened in Jan. 1927. Outside Europe and America courts are to be found in several parts of the British empire, especially in India and the far east. There are courts in New Zealand and in South Africa.

See E. H. Miles, Racquets, Squash Tennis (1902); C. Arnold, The Game of Squash Rackets (1926); E. B. Noel, The Field Handbook of Squash Rackets (1926).

(E. B. N.; A. DA.)

SQUIB, a firework bursting with a flash and a clatter; hence a slight satirical composition put forth on an occasion, which should make a noise by its explosion, not by the possession of any permanent importance. Steele says, in the Tatler, that "squibs are those who in the common phrase of the world are call'd libellers, lampooners and pamphleteers," showing that in his time the satirist as well as the satire was called a squib. Swift speaks of the rapidity with which these little literary fireworks flew about, and was himself a proficient in the making of them. A good type of a squib is Gray's Candidate. (See LAMPOON.)

SQUID, the popular name given to a large number of cephalopod molluscs which include (e.g.) the common squids of the Atlantic (Loligo, Ommastrephes), the giant squids (Architeuthis) and the fire squids (Lycoteuthis, Abralia). They are exclusively marine animals of world-wide distribution and form an important part of the population of marine swimming and floating animals.

A typical squid, e.g., Loligo vulgaris, the common squid of the north-east Atlantic and Mediterranean, has an elongate slender body (visceral sac) edged by triangular fins, a short square head provided with well-developed eyes and ten arms. On the undersurface of the latter are arranged rows of suckers which are strengthened by tough horny rings. Two of the arms (tentacles) are longer and more mobile than the other eight (sessile arms) and the suckers are concentrated at the extremity as a "hand." The long tentacles are used for capturing prey, the sessile arms for transferring the latter to the mouth and grasping it while it is being crunched by the horny jaws which are situated around the mouth in the centre of the circlet of arms.

Situated within the muscular tissues of the "mantle" is a long horny structure, the "pen" or gladius. This is the rudiment of a shell and consists actually of a secondary growth (the proostracum) which has replaced the true shell-rudiment. In the genus Ommastrephes there is a vestige of the original shell.

The majority of the squids are active, highly mobile animals of aggressive habits and are probably all carnivorous.

Originally the squids were distributed among the two "tribes," Oigopsida and Myopsida, of the ten-armed Cephalopoda (Decapoda). Recently, however, Naef and other students have proposed a more suitable classification of the Decapoda according to which the squids are all placed in a single sub-order, the Teuthoidea.

These forms are divisible into two groups originally called by C. Chun the Oigopsida libera and Oigopsida consuta. The first include the large, active and freely swimming forms (Architeuthis, Loligo, Ommastrephes, etc.). The second comprise a smaller assemblage of curious and highly modified forms which are less common than the Libera and are very largely planktonic. The distinction between these two groups is based on the mode of attachment of the ventral edge of the mantle to the head. In the Libera this attachment is effected by a stud and socket junction (see Cephalopoda) between the head and the edge of the mantle and can be freed from the head when necessary. In the Consuta the ventral edge of the mantle is permanently fixed to the head.

The Libera are represented by about 65 genera. Among them Architeuthis is the most striking on account of its size. The genus includes the largest living invertebrate animals, Architeuthis princeps of the north Atlantic attaining a maximum record length of 52 ft. (including the outstretched tentacles). Sthenoteuthis, a group of smaller forms, which attain a size of over seven feet, may be also reckoned as "giant squids."

Another interesting group are the phosphorescent squids, Nematolampas, Thaumatolampas (Lycoteuthis) and Abralia, which bear light-organs in certain regions of the body (on the mantle, arms, inside the mantle-cavity and around the eyes). Certain of these when seen alive are very beautiful. Ommastrephes bartrami, the so-called "flying squid," is found throughout tropical and temperate seas. Its flight is, strictly speaking, a series of leaps across the surface of the sea which are often strong enough to land it on the deck of a ship. This feat is no doubt rendered easier in high seas. The Consuta are mainly small animals. Their fins are largely reduced and the mantle is swollen and tun-like in Cranchia, Bathothauma, etc. In the latter, and in Sandalops, and Corynomma the arms are much reduced and the eyes are situated on stalks. Unlike the larger swimming squids these animals probably float largely at the mercy of the currents and are thus to be reckoned as "plankton." (See CEPHALOPODA.)

reckoned as plantoun (co. See G. Pieffer, Die Cephalopoden der Plankton-Expedition (1912); C. Chun, Wiss. Ergebn. d. Deutsche Tiefsee Expedn. Bd. xviii. (1910); G. C. Robson, A monograph of the recent Cephalopoda, vol. 1 (1929) (G. C. R.)

SQUILL, the name under which the bulbous root of Urginea Scilla (family, Liliaceae) is used in medicine. The medicinal squill is a native of the countries bordering the Mediterranean,

and grows from the sea-level up to an elevation of 3,000ft. The bulbs are globular and often weigh more than 4lb. Two varieties are met with, the one having white and the other pink scales. They are collected in August, when leafless, the membranous outer scales being removed and the fleshy portion cut transversely into slices and dried in the sun.

Three pharmacopoeial preparations of this powerful drug are of importance: the syrup, composed of one part of squill, eight of dulute acetic acid and four of sugar; the Philus Ipecacuanhae cum Scilla, in which ipecacuanha and opium are the chef constituents; and the In which pectangual and open art of squill with five of alcohol. The drug is a cardiac stimulant. Even in small doses it is a powerful expectorant and a fairly active diuretic. The drug must not be given alone, owing to its irritant action.

An allied species, Urginea indica, is used in India in the same manner as the European species. The true squills are represented in Great Britain by two species, Scilla autumnalis and S. verna. These are confined to the sea-shore. There are 80 species or more in temperate regions of the old world. Several species are grown in gardens, notably S. bifolia and S. sibirica, originating from the Caucasus region and S.W. Asia. S. nonscripta or English bluebell and S. hispanica or Spanish bluebell are also widely cultivated.

SQUINCH, in architecture, a general term for several means by which a square or polygonal room has its upper corners filled in to form a support for a dome: by corbelling out the courses of masonry, each course projecting slightly beyond the one below: by building one or more arches diagonally across the corner; by building in the corner a niche with a half dome at its head, or by filling the corner with a little conical vault which has an arch on its outer diagonal face and its apex in the corner. The arched squinch seems to have been developed almost simultaneously by the Roman builders of the late imperial period and the Sassanians in Persia.

Squinches are often found both in Romanesque and Mohammedan work. In Italy the form is either the conical type as in the church of S. Ambrogio at Milan (crossing 11th or 12th century) or as a succession of arched rings as in the 13th century central tower of the abbey church at Chiaravalle Milanese; more complex forms, with niches and colonnettes are characteristic of the French Romanesque of Auvergne, as in the cathedral of Le Puy en Velay (late 11th and early 12th century); the allied churches of the south-west coast, such as St. Hilaire at Poitiers, use conical squinches of the Italian type. Mohammedan architecture, borrowing from the Sassanian precedent, makes great use of squinch forms, particularly in the Syrian, Egyptian and Moorish phases; the stalactite work, which is so marked a feature of later Muslim architecture, is, in essence, merely a decorative development of a combination of niche squinch forms. In Gothic architecture squinch arches are frequently used on the insides of square towers to support octagonal spires. (See Byzantine and ROMANESQUE ARCHITECTURE; DOME; PENDENTIVE.)

SQUIRREL, the name of a red, bushy-tailed arboreal rodent, but also extended to include allied species. Typical squirrels are found throughout the tropical and temperate regions except

in Madagascar and Australia.

The common squirrel (Sciurus vulgaris) is found over the whole of Europe and North Asia, though showing great range of colouring in the various parts of its habitat. The ears are tufted, and the animal feeds largely on vegetables and fruits, varied with mice, small birds and eggs. In North America this species is replaced by the gray S. carolinensis, a larger and more powerful form, that has been introduced into Great Britain, where it has

GRAY SQUIRREL (SCIURUS CAROLI-NENSIS), EASTERN NORTH AMERICA

exterminated the native species in many places. Squirrels vary in size from that of a mouse, as Nannosciurus minutus of West Africa, to that of a cat, as the black and yellow Ratufa bicolor of Malay. In India the commonest species are the little striped

palm squirrels, Funambulus palmarum and F. pennanti, the latter being the more northern species. One oriental squirrel (S. caniceps) assumes a definite breeding dress. Squirrels form the family Sciuridae of the order Rodentia (q.v.). (See also Ground Squir-REL, SPINY SQUIRREL, GROOVE-TOOTHED SQUIRREL, FLYING SQUIR-

SQUIRREL FISHES (Holocentrus), a genus of small (less than a foot long), tropical, marine fishes, numerous about coral

SOUIPPE FISH CHOLOCENTRUS DIADEMA). ONE OF THE COMMONEST IN THE INDO-PACIFIC, RED IN COL-OUR WITH LENGTHWISE WHITE

reefs. They have notably large eyes, astrong backwardly directed spine at the corner of the preopercle (on the lower side of the head), a long spinous dorsal fin contiguous with a shorter one of soft rays behind it, a short anal fin with one of its initial spines notably long and strong, a forked caudal (or tail) fin, and the body covered with firm scales of moderate size. Their colours are

bright-red and yellow-and lengthwise stripes on the body predominate. Those with larger mouths (Flammeo) are sometimes separated generically from those with smaller mouths (Holocent-

Some 12 species of squirrel fishes inhabit the waters of the East Indies: 9, some of which are the same, those of the Hawaiian Islands; about 7 (of which Holocentrus adscensionis is the commonest), the West Indian region. (J. T. N.)

SQUIRREL MONKEY, a small golden-haired South American monkey, Saimiri sciurea; the name is also applied to the two other species of the genus, whose collective range extends from Costa Rica to Bolivia and Brazil. The squirrel monkeys belong to the Cebinae (see CAPUCHIN MONKEY), from the other members of which they differ by their practically non-prehensile tails, smaller size, their large eyes and the backward prolongation

of the hinder part of the head. (See PRIMATES.)

SQUIRREL-TAIL GRASS

SQUIRREL-TAIL GRASS (Hordeum jubatum), a name widely given in the United States to a species of wild barley, native to Europe, Asia and western North America and naturalized extensively in the eastern States and Canada, often becoming a troublesome weed, especially in alfalfa fields. It is a perennial, with slender stems usually from I to 21 ft. high, bearing nodding, soft, brushlike, long-awned flowering spikes, from 2 to 4 in. long and about as thick, whence the common name. It is also known, locally as barleygrass, foxtail and tickle-grass.

SRINAGAR, capital of the state of Kashmir, in Northern India, 5,250 ft. above sea-level, on both banks of the river Jhelum, which winds through the city with an average width of 80 yds, and is crossed by seven wooden bridges. The houses occupy a length of about 3 m. and a breadth of about 1 m. No two buildings are alike. The curious grouping of the houses, the frail tenements of the poor, the substantial mansions of the wealthier, the curious carving of some, the balconies of others, the irregular embankment and the mountains in the background form a quaint and picturesque spectacle. Pop. (1941) 207,787. The city is exposed to both fire and flood. The artisans of Srinagar enjoy a high reputation. Unfortunately, the historic industry of shawl-weaving has been replaced by carpet manufacture. Other industries are paper, leather, silver and copper ware, and wood-carving.

SRIRANGAM, a town of British India, in Trichinopoly district. Madras presidency, 2 m. N. of Trichinopoly city. Pop. (1941), 26,676. It stands on an island of the same name, formed by the bifurcation of the river Cauvery and by the channel of the Colesoon The town is celebrated for its great temple, dedicated to Vishnu, composed of seven square enclosures, one within another, and 350 ft distant from each other. Each enclosure has four gates with high towers, placed one in the centre of each side opposite to the four cardinal points. The outer wall of the temple is not less than 4 m in circumference. It is a great place of pilgrimage.

STAAL, MARGUERITE JEANNE CORDIER DE-LAUNAY, Baionne de (1684-1750), French author, was born in Paris on Aug 30, 1684, the daughter of a painter named Cordier She adopted her mother's maiden name, Delaunay. She was educated at a convent at Evreux, later accompanying Madame de Gricu to the convent of St Louis where the latter was anpointed abbess Mile. Delaunay held a little salon there until 1710, and after the death of Mme de Grieu entered the household of the duchesse du Maine at Sceaux. She helped her mistress to draw up the Mémoire des princes légitimes, demanding the meeting of the states-general. After a short imprisonment in the Bastille, on account of her implication in the Cellamare conspnacy (1718), she returned to the service of the duchess. She had had many admners, and some serious passions, when, in 1735, being then over fifty, the duchess arranged her marriage with the Baron de Staal. She remained a member of the duchess's household, and became the friend and correspondent of Mme. du Deffant. She died at Gennevilhers on June 15, 1750.

Her Mémoires appeared about five years later, and have often been reprinted. In these memoirs the humours of the "court of Sceaux" are depicted as hardly any other society of the kind has ever been. "Dans cet art enjoué de raconter," ' says Sainte-Beuve, "Madame de Staal est classique."

Her Mémoires were edited (1877) by M. de Lescure, and translated by S. Bathurst (1877) and by C. H. Bell (1892). Mme. de Staal also left two excellent short comedies, performed at the court of Sceaux, and some letters.

STABAT MATER, famous mediaeval Latin hymn on the Crucifixion, which has enjoyed unexampled esteem throughout the ages, believed to have been written by Jacopone, a Franciscan monk of the 13th century. Though not originally intended for this purpose, it was early introduced into liturgical use and was adopted as one of the Sequences of the Roman missal in the 18th century Among the many settings of the poem by eminent composers may be mentioned those of Josquin des Prés, Pales-trina, Pergolesi, Haydn, Rossini, Verdi and Dvořák

STABIAE, an ancient town of Campania, Italy, on the coast at the east extremity of the Gulf of Naples (mod. Castellammare di Stabia). It was dependent upon Nuceria Alfaterna. In 80 B.C. it was taken and destroyed by Sulla, and its territory given to Nuceria as a reward for fidelity to Rome

STADE, a town of Germany in the Prussian province of Hanover, situated on the navigable Schwinge, 32 m. above its confluence with the Elbe, 20 m. W of Hamburg on the railway to Cuxhaven Pop. (1939) 19,592. The rise of Harburg has deposed it from its former position as the chief port of Hanover

STADION, JOHANN PHILIPP KARL JOSEPH (1763-1824), Austrian statesman, was ambassador in London (1790-93). After some years of retirement he was entrusted (1800) with a mission to the Prussian court, where he endeavoured in vain to effect an alliance with Austria. He had greater success as envoy at St. Petersburg (Leningrad), where he played a large part in the formation of the third coalition against Napoleon (1805). Notwithstanding the failure of this alliance he was made foreign minister, when he helped to prepare archduke Charles for a fresh trial of strength with France. In 1808 he abandoned the policy of procrastination, and with the help of Metternich hastened the outbreak of a new war. The unfortunate results of the campaign of 1809 compelled his resignation, but in 1813 he was commissioned to negotiate the convention which finally overthrew Napoleon.

See A. Beer, Zehn Jahre österreichischer Politik, 1801–1810 (Leipzig, 1877); Die Finanzen Ossterreichs im 19 Jahrhundert (Prague, 1877). See also Austria, Empire of.

STADIUM, the Latin form of a Greek word for a standard of length. A stade = roo δργυιαί (about 6 ft or one fathom) = 6 πλάθρα (100 Greek or about 101 English feet) = about 606 English feet, or about one-eighth of a Roman mile. The course for the foot race at Olympia was exactly a stade in length, and thus the word for measurement became transferred first to the race and then to the place in which it was run. In modern usage stadium is one of several words applied to a large construction which combines space for games and seats for spectators, such as those erected for football. The Greeks built one of the first at Olympia, for the famous games held there The Romans built several types of structures for similar purposes: circuses, amplitheatres, also called arenas; and naumachia, which could be flooded for naval engagements The most famous of the Roman amphitheatres was the Colosseum at Rome (See Amphitheatre: ARENA )

Sports played a minor role in men's lives for many centuries after the fall of Rome, and it was not until modern times that permanent stadia were again needed. In the interim temporary stands such as those built from time to time in the Place des Vosges in Paris for jousting sufficed. An exception should be made of the court of the Belvedere in the Vatican, built in 7500 by Bramante. There the terraces were arranged to accommodate spectators when tournaments were held.

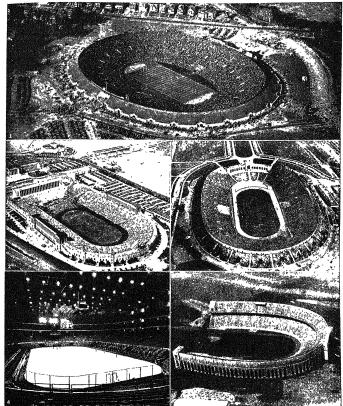

During the 19th century systematic physical exercise was revived. This led to organized athletics, which became as popular as in ancient Greece. Hence the building of large permanent stadia was also revived The first important stadium of modein times was the reconstruction, in Athens in 1896, of an ancient marble one built about AD. 170 by Herodes Atticus on the site of a still earlier Greek circus. It seated 66,000 persons, and was undertaken for the first of the modern series of Olympic games.

Although a few other stadia were built before 1900, such as arenas for bullfighting in Spain and Mexico, the great era of modern stadia building was the early 20th century, which by 1930 had seen the construction of more stadia than in any other equal period. In the United States alone more than 100 large stadia had been built. The early 20th century also witnessed the development of a new type of stadia, unknown to the ancients and made possible by modern building techniques, the indoor stadium. This type, completely enclosed and lighted by electricity, could be used night and day the year around The first important one was the old Madison Square Garden, built in New York city in 1800. It was replaced in 1925 by another of the same name seatmg 18,000. Others were built in London and Chicago. The Chicago stadium was the largest indoor stadium in the world in 1944. This type was flexible enough to be used for all court sports including those held on ice, and also for public meetings such as conventions, circuses and even concerts.

After 1930 fewer large stadia were built, not only because of the economic depression, but because there were so many in existence, and also because the era of spectator sports had apparently reached a peak, while the popularity of participating sports was increasing. The fascist countries were an exception, however, as great sports fields, of which a large stadium was a feature, were

built there during the 1930s.

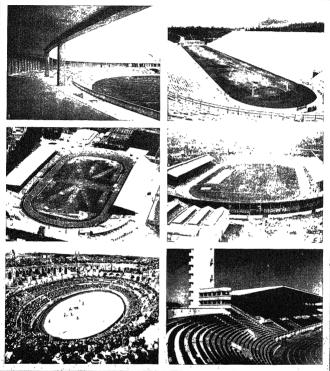

The following data illustrate the phenomenal increase in stadium building after 1900. Whereas in 1913 there were only 5 large stadia in the United States, by 1930 there were more than 100 During the decade of the 1920s alone 18 huge stadia, each seating more than 50,000 spectators, were erected Most of these were built for college athletic contests, particularly football. Others were built by private or municipal funds. Four of the largest stadia in the world were built in the United States. The Los Angeles Colosseum, built in 1923, was enlarged in 1932 to accommodate 125,000 persons and renamed the Los Angeles Olympic stadium. The Philadelphia Municipal stadium, built in 1926 for the Sesquicentennial exposition, held 130,000. The Cleveland Public stadium, built in 1931, held over 100,000. In Chicago, Soldier Field, opened in 1926, had permanent seating for 125,000 and could be extended to accommodate more than 200,000. Thus Chicago had the largest permanent stadium of modern times.

STAËL

273

Olympic Stadia have been among the most impressive of stadia. Nearly every country in which the games were held exceted a great permanent stadium for the event. The first stadium of the modern type providing for the full range of the moden program of Olympic events, which is much expanded over its classic prototype, was that built in London, at Shepherd's Bush, in 1996 for the IVth Olympiad.

It provided a conder track, one-third of a mile long, which bounded a turn fare for field events 243 yell by 90 yd. There was for a pool for swimming events, with sufficient depth for drung, and a cycle track. The stands, part of which were rofeel, accommodated 50000 seats. Other Olympic stadia of interest were the Stockholm one of 1912, the severely simple one at Colombes, near Paris, built in 1924, the handsome brick one built at Amsterdam in 1928, and most elaborate of all, that built in Berlin in 1936, for the Xith and last Olympiad to be held before war broke out in 1939.

The nazi government erected the most extensive facilities for sport the world had ever seen. The large stadium, seating roo,coo, was only one of several stadia in the group. The group as a whole was of a sombie, brutal massiveness.

The Berhn sports field just described was but one of many great sports fields each with one or more stadia built by the nazis and fascists during the 1930s. These were part of the program to develop strong youth for the future armies. In this respect they were unlike the stada of the 1930s which had no ulterior purpose. The fascist stadia were elso adaptable for party congresses.

The Deutsche Stadion, Nürnberg, 1937, was the most colossal. Its large scale and enormous extent, almost double the capacity of the Roman Circus Maximus (reputed to be 225,000), gave a solemn dignity to the ceremomes staged in it.

Plans.-The shapes of stadia have varied widely, reflecting the variety of uses for which they have been built. Some were designed for one sport only, such as the Yale Bowl, built in 1014. with a capacity of 80,000, the first modern one to surpass the canacity of the Colosseum. Like its Roman predecessor it is a closed ellipse in plan The Harvard stadium, built in 1012 was U-shape, open at one end to permit both football and track events Others have been built to permit baseball as well. Those built for Olympic games have generally been rectangular to enclose a large playing field, and with rounded corners for the track, as in Berlin, 1036. The horseshoe shape has also been used as at Ohio State university in 1922. The most flexible shape was that providing two parallel stands, opposite each other, with the narrow ends open. Some of this type have been built with superimposed tiers of seats, others with crescent-shaped stands (Northwestern university, 1926) so that as many seats as possible were opposite the centre of the field Still other types have been used for special purposes, such as the Yankee stadium, New York city, 1923, built primarily for baseball, and Forest Hills, Long Island, built for tennis.

Structure.- The building of large stadia in the early 20th century was stimulated by the invention of the automobile and the new material-reinforced concrete. This material is relatively cheap for large structures, but has not proved entirely satisfactory in temperate climates as it weathers badly. Nevertheless, in the hands of skilful engineers and careful workmen, especially in Europe, magnificent stadia have been built in reinforced concrete which daringly exploited the potentialities of the material. Some of the fine examples follow. Lyon, built in 1920 by Tony Garnier Florence, the Giovanni Berta stadium, built in 1933 with fantastic external stair towers expressionistic in style. Bordeaux, built in 1939, remarkable for a roof of graceful arched sections. Helsinki, built for the XIIth Olympiad which was cancelled by the outbreak of war in 1939. The bold tower there was a striking feature. Projects have been designed, though not executed, making use of other structural forms, such as one by Le Corbusier with a roof constructed as the wings of aeroplanes are constructed. Eventually, making use of war-inspired scientific advances, it may be possible to build large stadia completely weatherproof.

(C. L. V. M.)

STARL, MADAME DE. ANNE LOUISE GERMAINE NICKER, BARONNE DE SIAFL-HOLSTFIN (1766-1817), French novelist and miscellaneous writer, was born at Paris on April 22, 1766 Her father was the famous financier Necker, her mother Suzanne Curched almost conally famous as the early love of Gibbon, as the wife of Necker himself, and as the mistress of one of the most popular salons of Paris The future Mme de Stael was from her earliest years a romp, a coquette and passionately desirous of prominence and attention She was a plain child and a plainer woman, whose sole attractions were large eyes and a buxom figure. She is said to have written her father a letter on his famous Compte-Rendu and other matters when she was not fifteen, and to have injured her health by excessive study and intellectual evoltement. There is no doubt that her father's dismissal, and the consequent removal of the family from the busy life of Paris, were beneficial to her During part of the next few years they resided at Coppet, her father's estate on the Lake of Geneva, which she herself made famous They returned to Paris. or at least to its neighbourhood, in 1785, and Mile Necker resumed literary work of a miscellaneous kind, including a novel, Sophie, printed in 1786, and a tragedy, Jeanne Grey, published in 1790. She married Eric Magnus, Baron of Stael-Holstein, who was first an attaché of the Swedish legation, and then minister, For a great heiress and a very ambitious girl the marriage scarcely seemed brilliant, but the king of Sweden promised the ambassadorship for twelve years and a pension in case of its withdrawal, and the marriage took place on Jan. 14, 1786. The husband was thirty-seven, the wife twenty Mme. de Stael was accused of extravagance, and after 11 years (1797) an amicable separation of goods was arranged There was no scandal between them; the baron obtained money and the lady obtained, as a guaranteed ambassadress of a foreign power of consideration, an established position. In 1788 she appeared as an author under her own name (Sophie had been already published, but anonymously) with some Lettres sur J J. Rousseau She stood at this time for a mixture of Rousseauism and constitutionalism in politics. She visited Coppet once or twice, but for the most part in the early days of the revolutionary period she was in Paris taking an interest and, as she thought, a part in the councils and efforts of the Moderates At last, the day before the September massacres, she fled from France, befriended at this critical juncture by Manuel and Tallien.

She betook herself to Coppet, and there gathered round her a considerable number of friends and fellow-refugees In 1793 she visited England, and established herself at Mickleham in Surrey as the centre of the Moderate Liberal emigrants-Talleyrand. Narbonne, Jaucourt and others. In the summer she returned to Coppet and wrote a pamphlet (Réflexions sur le procès de la reine) on the queen's execution. The next year her mother died, and the fall of Robespierre opened the way back to Paris. M de Stael (whose mission had been in abevance and himself in Holland for three years) was accredited to the French republic by the regent of Sweden; his wife reopened her salon and for a time was conspicuous in the motley and eccentric society of the Directory She also published several small works, the chief being an essay De l'Influence des passions (1796), and another De la Littérature considérée dans ses rapports avec les institutions sociales (1800) It was during these years that Mme. de Staël was of chief political importance Benjamin Constant, whom she first met at Coppet in 1794, had a very great influence over her, as in return she had over him Both personal and political reasons threw her into opposition to Bonaparte. Her own preference for a moderate 1epublic or a constitutional monarchy was quite sincere, and, even if it had not been so, her own character and Napoleon's were too much alike in some points to admit of their getting on together For some years, however, she was able to alternate between Coppet and Paris without difficulty, though not without knowing that the First Consul disliked her In 1797 she, as above mentioned, separated formally from her husband. In 1799 he was recalled by the king of Sweden, and in 1802 he died, duly attended by her. They had three children: Auguste-Louis, Albert and Albertine, who married Victor, duc de Broglie.

The exact date of the beginning of what Mme de Stael's admirers call her duel with Napoleon is not easy to determine Judging from the title of her book Dix années d'exil, it should be put at 1804, judging from the time at which it became pretty clear that the first man in France and she who wished to be the first woman in France were not likely to get on together, it might

be put several years earlier In 1802 she published the first of her really noteworthy books. the novel Delblane In 1803 she returned to Paus She was directed by order of Napoleon not to reside within so leagues of Paris, and after considerable delay she set out, in company with Constant, by Metz and Frankfurt to Weimar, and arrived there in December There she staved during the winter and then went to Berlin, where she made the acquaintance of August Wilhelm Schlegel, who afterward became one of her intimates

at Coppet Thence she travelled to Vienna, where the news of

her father's death (April 8) reached her

She returned to Coppet and found herself its wealthy and independent mistress, but her sorrow for her father was deep and certainly sincere. She spent the summer at the château with a brilliant company, in the autumn she journeyed to Italy accompanied by Schlegel and Jean de Sismondi, and there gathered the materials of her most famous work, Cornine She returned in the summer of 1805, and spent nearly a year in writing Corunne; in 1806 she broke the decree of exile and lived for a time undisturbed near Paris

In 1807 Cornue, the first aesthetic romance not written in German, appeared It is, in fact, what it was described as being at the time of its appearance, "a picturesque tour couched in the form of a novel" The publication was taken as a reminder of her existence, and the police of the empire sent her back to Coppet. She stayed there as usual for the summer, and then set out once more for Germany She was again at Coppet in the summer of 1808 (in which year Constant broke with her, subsequently marrying a German lady) and set to work at her book, De l'Allemagne, which occupied her for the next two years. She decided to publish the book in Paris The submission to censorship which this entailed was sufficiently inconsistent and Mme de Stael wrote to the emperor one of the unfortunate letters, at once undignified and provoking, of which she had the secret. The reply to her letter was the condemnation of the whole edition of her book (10,000 copies) as "not French," and her own exile from France She retired again to Coppet, where she was not at first interfered with, and she found consolation in a young officer of Swiss origin named Rocca, 23 years her junior, whom she married privately in 1811

The operations of the imperial police in regard to Mime. de Staël are 1ather obscure She was at first left undisturbed, but by degrees the château itself became taboo, and her visitors found themselves punished heavily Mathieu de Montmorency and Mme. Jeanne Françoise Récamier were exiled for the crime of seeing her. On May 23 she left Coppet almost secretly, and sourneved by Bern, Innsbruck and Salzburg to Vienna There she obtained an Austrian passport to the frontier, and, after some trouble, receiving a Russian passport in Galicia, she escaped from

Napoleonic Europe

She journeyed slowly through Russia and Finland to Sweden, making some stay at St. Petersburg, spent the winter in Stockholm and then set out for England. Here she received a brilliant reception and was much lionized during the season of 1813. She published De l'Allemagne in the autumn, was saddened by the death of her second son Albert, who had entered the Swedish army and fell in a duel brought on by gambling, undertook her Considérations sur la révolution française, and, when Louis XVIII had been restored, returned to Paris. She was in Paris when the news of Napoleon's landing arrived and at once fled to Coppet, but a singular story, much discussed, is current of her having approved Napoleon's return. There is no direct evidence of it, but the conduct of her close ally Constant may be quoted in its support, and it is certain that she had no affection for the Bour-

In October, after Waterloo, she set out for Italy, not only for the advantage of her own health but for that of her second

husband, Rocca, who was dying of consumption Her daughter married Duke Victor de Bioghe on Feb 20, 1816, at Pisa whole family returned to Coppet in June, and Byron now frequently visited Mme de Stael there

Despite her increasing ill-health she returned to Paris for the winter of 1816-17, and her salon was much frequented She died

on July 14, 1817.

Baron Auguste de Stael (d 1827) edited the complete works of his mother in 17 volumes (Paris, 1820-21), with a notice by Mme Necker de Saussure, and the edition was afterward republished in a compacter form, and, supplemented by some Oeuvres médites, is still ob-tainable in three volumes, large octavo (Didot) The Considerations tamable in three volumes, large octavo (Didot) The Considerations and the Dr. années d'evil had been published after Mme de Stael's death Some Lettres néedies to H Meister were published in 1903 There is no recent reissue of the whole, and the minor works have not been reprinted, but Corune, Delphine and De PAllemagne are easily accessible in cheap and separate forms of separate works on Mme de Stael, or rather on Coppet and its society, besides those of MM

de Stael, or iather on Coppet and its society, besides those of MM Caro and Othern d'Hausson/tle, may be mentoned the work of A Sorel in the Corands correases françair. In English there are boquephies See also E. Hernot, Urn owneys midst de Mme de Stael (1904), P. Kohler, Mme de Stael et la Susse, Elisde bographique et in-terme (Laussine, 1918), I. Boy-B.G. Germane von Stael (Stuttgart, Caroline, 1918), I. Boy-B.G. Germane von Stael (Stuttgart, 1914); I. Boy-B.G. Germane von Stael (Stuttgart, 1914); I. Br. B. F. G. Celteron, Mm. de Stael et M. Necker, 4daprès leur correspondance midital (1923).

who assist the commander of a military force. The basic meaning of the term is similar in all armies, though staff organizations and

their functioning vary considerably

As armies increased in size and complexity, commanders were unable to win victories without staff assistance Commanders, no matter how capable, could not keep watch on the multitude of details involving recruitment, intelligence, operations and plans, and supply. When numerous divisions and corps were included in armies, the top commander was unable to maintain contact with the subordinate units Assistance was obtained by the creation of staffs, including officers and enlisted men, to handle the numerous details of command. Though assistants gave advice to the commander, they had no authority to give orders, except in the name of the commander Eventually, it became necessary to co-ordinate the activities of the staff through a chief of staff. The procedures of the staff, its rights and responsibilities and its place in the armed forces became known as the "functions of the staff

As a later development, the term "general staff" came into existence. It was first used in 1809 by the Prussians to indicate the staff assisting the general commanding the troops of an entire army. However, when forces became larger and many armies were created, the term "general staff" was used for the highest headquarters. As a further amendment the term "general staff," when followed by the designation "with troops," named the staff officers assigned to major subordinate headquarters There they performed duties similar to those at the highest headquarters

Other terms concerning staff functions developed later, such as 'special staff," "administrative staff" and "technical staff" These experts in supply, ordnance, administration and the like were essentially advisers, having no staff functions of policy and management comparable to the general staff. Normally, special staff officers have two functions, advice in their specialty and command of service or administrative troops

## HISTORY OF MILITARY STAFFS TO 19TH CENTURY

Ancient Armies.-Staffs in the early armies of Persia, Greece and Rome were usually on an informal basis. The commander was in complete charge in battle; his orders were sent to subordinates through messengers or aides de camp and the quaestor or supply officer.

Both Athens and Rome maintained committee commands in their armies. In Athens authority was exercised by ten strategoi, literally generals, under whom were ten taxiarchs who were in charge of subsistence, construction of camps, the orderly conduct of marches and had limited command functions.

When Caesar came to power in Rome he found a curious system of command in the army, each legion being commanded by a committee of six tribunes Divided into sets of two, each pair commanded the legion for a definite period or companya, Laing the lader's position on alternate days. Somewhat similar to the Achenian command by the ten stratego, it was a straige though accessful system. Whether the battles were won despite the command system is a moot point. One advantage was that the tribunes not in command were eligible for staff duty as assistants to the commander. Caesar modified this committee system of command by placing a legate as the leader of the legion, utilizing the two frulness on duty as staff assistants.

During the middle ages when warfare was an individual affair among feudal chiefs, there was practically no development in the staff system and no need for it. However, the crusaders, who lacked a national character and were feudal theirs and set is bound together by a religious mission or spirit of adventure, learned that their operations and movements needed co-ordination. No one looked after their ships or assured supplies of food, weapons, sege equipment and horses. Defeat convinced the crusaders of the need for assistants to control and co-ordinate their supply system.

need for assistants to control and co-ordinate their supply system Military staffs however, showed no significant development until the time of Gustavus Adolphus, when dynastic armies came into prominence

Gustavus to Napoleon.—The Swedish army of the 1620s was the best organized of any army up to that time It brought with it new tactus, an appreciation of held fortifications and a supply system which functioned smoothly. Gustavus Adolphus organized a staff nucleus in his regiments. Each headquarters included a colonel, a lieutenant colonel and a major, a quitermaster four suggeons, four provost marshals, two judge advocates and two chaplams, assasted by a number of clerks. The quartermaster was a vital member of the staft, being responsible for food supply and the movement and quartering of troops. Provisions were distributed to the regiments in bulk, subsequently being issued to the men by the regimental major, who was also called the "sergeant major." In addition to such duty, it was a logical step for the latter to assume administrative and operational functions.

The Swedish army was governed by regulations upheld by contra-martial, a system which endured in all armies. To enforce the regulations, the staff position of provost marshal was created These changes increased the staff duties in armies, but none would have been possible without punted regulations and orders. By Gustavus' time, the printed word for military orders was replacing the verbal orders in practice since the Greek and Roman armies

"Cromwell's New Model army followed on the heels of the Swedish army, giving new impetus to organizational innovations. His staff system, like that of Gustavus, was organized under a captain general, assisted by a chief of staff who was also chief of infantry and sergeant imago general. Connwell, as second in command to Sir Thomas Pariatx, was heutenant general and chief of cavalry. The other staff officers also doubled in brass; the commissary general as an assistant chief of cavalry; the chief of ordance as head of both artillery and engineers. In his insistence that all men be paid for services rendered, Cromwell required another staff officers, a commissary general of musters

Soon afterward, the French munister F-M. Louvois substantially improved the supply of ammes. He persuaded Louis XIV to introduce a staff officer known as the intendant who operated commissaries, pand the troops and procured and distributed supplies. Later the intendant's duties were restricted to finance and procurement, supply being directed by the marchala gladral das logis. Within the French army staff the logistical chief was on the same chelon as the marchala de battille, the chief of operations. Both served the field marshals commanding armies, who in turn reported to the marchala de France.

Subsequently, Louvois replaced the field marshals by a marshal of legistics, who with his assistants formed an army staff. Sébasticn Vauhan, the celebrated slege expert, was the inspector general of engineers, while Jean Martinet served the infanty. The latter demanded such rigid discipline that his name was given to all struct discribinaristics.

During the 18th century, Frederick the Great gave new impor-

tance to staff (unctioning For instance, he was assisted at all times by a quartermaster general whose duties were to survey and lay out camps, bridge streams and plan the defense of villages Frederick as a staff mentor also instructed a number of officer candidates in making reconnaissances, planning operations and using obstacles for flank protection of armies. He also founded in 1765 an academy of nobles for the training of young men in diplomacy and the military art. Subsequently he established a war academy and personally permed its regulations and course of instruction. These were the first schools for the training of staff officers.

Though he had an obvous interest in the education of military staffs, Frederick himself manitaned a very small staff of assistants. Rather than a lack of interest, it indicated that as both king and army commander he incorporated in his person many of the staff tunctions which might well have been delegated to staff specialist. He was an ardent engineer, paying particular attention to the building of roads, bridges and field fortifications, he was vitality concerned with tactics and supply. In effect, Frederick was list own military staff. Succeeding commanders, other than Napoleon, rarely held his combination of political and military power.

Napoleon.—Because Napoleon was both chief of state and commander of the arrny, and because of his mitiatory abilities no real general staff was required. Marshal Louis Alexandie Berthier was Napoleon's chief of staff, but in name only, since he acted more as an adjutant. Other staff officers were François de Chasseloup-Laubat, the chief of engineers, Nicolas Marie de Chasseloup-Laubat, and Perre Antonion Darut, the chief of the quartermisater department. Each of the latter also had his own personal staff.

Many of the famous French marshals were at one time adjutants general, assisting the cluef of the general staff for the army. The position of adjutant general had been created by the National Convention in 1792, as replacement of the former maréchal général des logis.

Berthier, a student of staff organization and functioning, reduced to writing the principal duties of the general staff. He placed great emphasis on the necessity for speed in staff work. The first real manual on staff procedure was, however, written by an adjutant general, Paul Thiebault. Basic staff theory and technique were included in the manual, insistence being given by the author to the requirement that staff officers responsible for reports make them "pieceies, accurate, and complete". The staff functions sot forth in the manual were based largely on Berthier's instructions to his stafful.

The first section included staff records, legal matters, personnel affairs such as recruitment, prisoner of war records and the like Supply of food, equipment and arms was the principal activity of the second section of the staff, though it also included the medical and military police staffs.

In addition to a division of functions, the staff manual set forth the essentials of staff knowledge and practice based upon army experience. On one occasion when Thebault was serving as a divisional staff officer, he was questioned by Napoleon, who was making an inspection. Thiébault was unable to tell him the supply struction and the enemy intelligence—all of which were embarrassing questions for the young staff ofheer.

The staff manual was the culmination of his resolve to systematics the handling of information so that it would be readily available to the commander. It included data on the functions of each staff officer, organization of the staff, allocation of work and detailed forms for staff reports, even to the number of paragraphs needed. He listed the higher staffs of the period as including the commanding general, chief of staff, aidles to the general, adjuttant general, intendants or finance officers, generals of artillery and engineers, health officers and the wagonmaster general.

In the United States, the duties of the staff were in no way developed as in the Napoleomic armies. Army legislation in 1796 constituted a general staff to include one major general, a brigadier general, an adjutant general, a quartermaster general and a paymaster general.

### DEVELOPMENT OF MILITARY STAFFS TO WORLD WAR II

German Staff System.—Gerhald von Schanhonst's roorganzation of the Prussna army after 1820 included a staff system During the succeeding years through World Wai I, the German general staff exeited the greatest influence on the development of modern military staffs. Men like Schamhorst, and Count August von Gensenau and Count Helmuth von Moltke after him, built upon the staff system of Frederick the Great Its prestage was overawing, mainly because of the German social system which gave the military a position of great influence The Japanese and Russans based their staff systems on the German model, in many cases German officers actually training their staff candidates

While it is true that the German general staff was built upon Geman ideas under Fredenck and Scharnborst, it was undoubtedly influenced by Napoleomic methods. Certain terms in staff procedure were taken directly from the French and even tetained their French spelling. Moreover, French ideas were brought into the Pressans staff system by French instructors at the war academy.

It was the Genmans who first began assigning general staff officers to subordnate headquarters. However, in being thus assigned they were not attached to the local general in command but to the organization so that in effect the ideas of the general staff at the highest headquarters permeated all the major subordinate commands. In Jost the highest staff became known as the great general staff and the other portion which was distributed to the army commands was known as the army general staff. In time the great general staff in Berlin became known for its dictatorial methods, its arrogance and its dominant role over the entire army A military caste was created which considered war as a national enterprise and their monopoly. The great general staff became permanent, independent and specialized.

The Prussan general staff through more than a century of war and peace gave to the term a connotation of arbitrary, militaristic and anstocatic power. Despite these handicaps, under Moltke in the latter part of the 19th century it was an extremely efficient organization. Its plans were complete and worked out to the last detail.

The staff organization had five sections, of which the first section was the general staff with responsibility for operations, intelligence, supply and administration and training. The other four sections were in sequence the adjuntat general, the pudge advocate, special services such as medical, pay, quartermaster and the like, and the chaplain service. The particula work of the staff was accomplished by three groups drawn from the five sections a tactical group consisting of operations and intelligence from the general staff in the first section, a supply group consisting of the supply branch of the general staff and the fourth section with attacked the pudge advocate and the chaplain from the second, third and fifth sections, respectively. The training function was exercised by the general staff without assistance from any of the other staff sections.

One other feature of the German general staff was rotation of officers for periods of general staff and troop duty. Thus the general staff gained complete control of the army by assuring that higher troop commanders were selected members of the general staff.

French Staff System.—In contrast to the development of the German general staff during the 19th century, the French staff system was moribund Cestain graduates of the French military schools of St Cyr and Ecole Polytechnique entered the Ecole Gittat-Major, stabhished in 18t8, where they learned the routine of staff procedure. For the remainder of their service they were members of a weak staff bureau, separated from the troops.

After the French defeat in the France-Frassian War, a true staffrollege, the Ecole de Guerre, was established in 1880. Its attention to strategy and higher staff training awakened the French staff system, so that by 1914 France had a well-trained staff on a par with that of Germany. Impetus in the French staff system also came from legislation in 1894 which set forth the basic regulations for staff organization and procedures.

Staff responsibilities were made specific, and staff channels were later fixed within an organization of three sections or bureaus

The first bureau was charged with organization, promotions, secruting and other personnel matters. Enemy information was the concern of the second bureau, while the third prepared orders and institutions for imitiary operations. A peculiarity of the French system was the decentralization of a fourth bureau, for supply, to the subordmate field commands. Thus the theory and technique of the French staff had gone through an evolutionary process before World War I, rising from its low point after the success of the Napoleomic era to a capable organization at the close

of the century

British Staff System.—By World Was I, the British general
staff was well trained, though too few in numbers to meet the war's
demands Staff development during the 19th century had been
extremely slow, little cognizance being taken of Prussian and
French methods H Spenser Wilkinson's The Brain of an Army
published in 1963, awakened Britan to the need for rehabilitation
of its staff system Its author purported to give the secret of
Moltke's success.

Fortunately, a staff college had been established in 1858, and though it had not produced the desired improvement in Brists staff practice it had provided a basis for development. In the Boer War the British command and staff system had exhibited many deficiencies. A report of inquiry by Lord Esher in 1904 resulted in a reform of the British staff.

Basacally, the British staff depended greatly upon committee efforts and upon co-ordination. Below the highest command there was no chief of staff, the functions of that office being divided among the general staff, the administrative ("A") staff and the quartermaster ("Q") staff. Prussan influence was evident in the system of having the senior general staff officer act as commander in the latter's absence. Furthermore, division of the administrative and service functions of the staff was reminiscent of the Cerman method.

Operations and intelligence were general staff functions, while the "A" and "Q" staffs were responsible for personnel and supply, respectively The British organization differed, however, from the German in that supply was a function of both the general staff and the "Q" section

The fact that the British staff varied from those of France and the United States (the latter based on the French organization\text{resulted in many complications in both World Wars I and II The Allied armies had to learn one another's staff procedure and terminology in order to function smoothly as combined forces

U.S. Staff System.—There was no general staff in the army of the United State during the right century. The adjusting temperal, quartermaster and other technical and administrative service chiefs were a law unto themselves. The commanding general had no direct authority over the various bureaus in the staff. When Gen William Tecumseh Sherman was commanding general after the Crul War, he threatened to move his office from Washington, D.C., because he had no control of the independent staff bureaus

Prevously, during the Civil War, the field commanders developed their own staffs, but there was no comparable development in the war department. Gen George B McClellan, when commander of the union army in 1861, complained of the lack of a staff system, probably forgetting that six years or before he had made no note of European staff methods when on an inspection committee. However, he improvised a staff, utilizing his inspector general as chef of staff

The creation of a general staff was not seriously proposed until after command failures in the Spanish-American War brought action by the secretary of was, Elihu Root He established a command and general staff school in 1902 and the next year obtained from congress authorization to organize a general staff. The list of its duties was borrowed from the Pressan, Paul Bronsart von Schellendorf, and its organization from the French. Staffs were formed in all headquarters, to include the infantry division, in World War I Five sections were organized under a chief of staff; personnel (G-1); intelligence (G-2); operations and plans (G-3); supply and transportation (G-4); and training (G-5).

### WORLD WAR II STAFFS

Changes in Staff Organization .- The social nature of war was well illustrated during World War II with two developments m military staffs The first requirement was for more specialists and therefore resulted in an increase in the size and complexity of military staffs The second development was the unified command of two or more forces or nations, testimony to the interlocking nature of modern war

The German, Japanese and soviet armies employed substantially the organization of the German general staff explained above The French and British systems were little changed from those of World War I but the U S general staff shifted war plans from G-3 to G-5, delegating training to the field forces

In all armies, World War II brought about certain changes designed to improve the efficiency of staff operation. For instance, the soviet general staff, which had always included topographical engineers, a historical division, security police and political commissars found that it had to eliminate the political commissars for a time because the troop commanders complained of divided command The Red army's historical division was charged with keeping an account of military operations of the higher ranking generals If unsatisfactory, commanders were summarily removed.

The U S war department staff was reorganized to include an air force and a service force staff in addition to the general staff. The latter underwent a change in that G-5, war plans, developed into the command post of the chief of staff and was designated the operations division This move, in practice, placed the operations division on a higher level than the other general staff divisions

Prewar staffs were found to be much too small both in function and number to handle the multitude of problems which arose in World War II. In most aimies, policy matters were the prerogative of the general staffs, technical functions and operational matters being delegated to subordinate headquarters which organized staffs along conventional lines. Administrative services of this kind were drawn together in a separate command known as rear area services in the Red army and communications zone headquarters in the U.S. army

Unified Staffs.-The second development, formation of joint and combined staffs, was peculiar to the total and global warfare of World War II. Blitzkrieg tactics, requiring the utmost cooperation between land forces and the air fighter support, underlined the necessity for commands containing both army and air force officers Similarly, amphibious operations brought in the navy as well, so that there was close staff co-operation among the three combat forces This union of the staffs of two or more services of one nationality was called a joint staff. The phenomenon was restricted to the central headquarters at home and to the theatre or highest overseas command headquarters. For instance both the U.S. and Great Britain formed supreme commands. known as the joint chiefs of staff in the United States, and the chiefs of staff committee in Great Britain. In both cases the joint staff at the seat of government was concerned with war plans, logistics support, intelligence, munitions production and other requirements of waifare, and included army, navy and air force staff officers In the field, the joint staffs were not co-ordinated to such a high degree since the commander of each dimension of warfare had his own staff and made arrangements for co-operation through committees or liaison, to assure co-ordinated accomplishment of the joint objective.

Co-ordination among Allies was effected through a combined staff of officers from two or more nations. The best demonstration of this type of staff were the two commanded by Gen. Dwight D. Eisenhower in his armed forces headquarters in Africa (AFHQ.), and in his supreme headquarters Alhed expeditionary forces (S.H A.E.F.) in Europe. In the latter staff, army, navy and air force officers and enlisted personnel, men and women, from Britain and the U S were formed into a true combined headquarters Under Eisenhower were field commanders for the army, navy and air force, the latter two being British and the first an American. His staff was organized on the basis that alternate staff

divisions, branches and sections were to be headed by alternate nationals British or American. The chief of staff was an American supported by two British deputy chiefs of staff, one for operations and intelligence and the other for administration and supply This was a merger of the British and US staff systems with a deputy for operations and intelligence, controlling the complete general staff in the British system, and the combined G-2, G-3 and G-5 in the U.S. system. The other deputy was both the "A" and the "Q" cluef in the British system and the G-1 and G-4 in the American In the staff divisions the G-1, G-3 and G-4 staff chiefs were American, and the G-2 and G-5 (the latter having become civil affairs and military government) were British

The functioning of such combined and joint staffs was complicated by differences in nomenclature and in staff channels. However, because of the educational processes of the previous century which were common to the staffs of all major nations, the preparation of policies and plans and the position of the staff as assistants to the commander were well accepted by all staft officers Furthermore, staff officers were acquainted universally with the co-ordination of their efforts by a chief of staff Also the relationship with tactical, technical and special staffs was similar in all armies In most cases, the ordnance, engineer, quartermaster and other technical specialists reported to the supply thief, the chaplams, adjutant general, finance officer and provost marshal reported to the personnel chief There was a slight difference in staff placement of signal communications, it being a part of the general staff in the British and soviet systems, but a technical service in the US and German staff systems

### TRENDS AFTER WORLD WAR II

The postwar trend in staffs was toward greater unification of effort and a reduction in the number of agencies reporting to a commander or chief of staff. The Soviet Union in 1046 followed Britain's lead of ten years before in the establishment of an armed forces general staff, and the United States tollowed suit in 1947 In both cases, this establishment of a unified staff was legal recognition of a system which had developed during World War II The soviet armed forces staff was largely controlled by army officers since the army had been the primary service in that country, the navy being rather small, and the air force a tactical group assigned for close support of the field armies. In Britain and the US there was increased use of the joint or unified staffs, and a further development of combined staffs under the North Atlantic treaty defense committee

The 12 nations signatory to the North Atlantic treaty agreed to set up regional military committees which required the combination on one staff of as many as five nationalities 
It was recognized that the language difficulty had to be hurdled first, then training and tactics had to be standardized. A precedent was set for the staff combination of more than two nations since S.H.A.E.F. included British and U.S. staff officers with French, Polish, Belgian and other nationalities in a haison capacity.

Standardization as well as more complex staffs in keeping with the progressive scientific nature of war had become the trend in organization of military staffs.

The progressive source that the Co was and Decorate trees the Bratton of military staffs.

cers delegated to advise and assist a flag officer in the administration and operation of his command In the sailing-ship era simplicity of operations, cramped quarters and short range of communications restricted staffs to one or two officers. The technological revolution of the 19th century, progressively magnifying and complicating the problems of naval command, enlarged the size and functions of staffs so that in the Civil War as many as eight staff officers were detailed to an admiral, in World War I Adm William S Sims, the commander of US naval forces in Europe, recruited a shore-based staff numbering in the hundreds, and in World War II Adm Chester W Nimitz, naval commander in the Pacific, counted his staft in the thousands Radio facilitated the staff growth in World War I by permitting concentration of authority In World War II the necessity of co-ordinating land, sea and air forces swelled staffs still further

Naval staffs today are grouped in two categories, operational and administrative A single staff may fall in both categories but separation promotes standarduction of administration and relieves combat officers of petty details. Operational staffs, small and mobile, accompany task force commanders into battle assisting with the planning and eaceution of combat missions. Administrative staffs usually base ashore or in large auxiliary ships supervising maintenance, alteration, supply and training of a particular type of ship within a fleet. As an example, in World War II the commander of destroyers of the Pacific fleet never commanded destroyers in battle but he and hus staff did check destroyers for readiness of me and material. Similar administrative commands and staffs specialized in such types as cruisers, battleships, amphibous vessels, carriers and their aircraft.

A typical seagoing operational staff in 1950 comprised about 20 officers with at least as many enlisted cliental assistants and technicians. The enlisted men were not staff members but constituted the "enlisted flag complement." The staff was compartment onto five functional divisions administration, intelligence, operations, logistics and communications. These divisions were sectioned into such diverse technical fields as guinnery, aviation, supply, medicine, public information and amphibious operations. The staff officers were not always specialists in the particular fields to which they were assigned.

Three officers were assigned as the flag officer's ardes and each were a distinguishing agualletic One of these, the chief of staff, always the senior staff officer, co-ordinated all staff activities A second, the flag secretary, was the administrative officer in charge of correspondence and office routine. A third, the flag laustenant, was personal ande and staff signal officer. A these, staff offices of the line stood watch on the flag bridge or in the operations centre, transmitting the admiral's orders to the shines of his command.

An administrative staft ashore was organized along similar lines to an operational staff but naturally placed emphasis on normothet fields such as logistics, training and administration. Normally flag officers ashore had but two aides, one the chief of staff, the other called simply the "aide".

Staff organization at the top of the mavy, a product of long overvolution, din ot conform to the pattern of the lower exclusion nor to the army's general staff system. After 1798 a civilian secretary of the navy reheaved the presendent of the details of his task as commander in chief of the navy From 1842 the secretary was advised and assisted by professional officers, each the chief of a technical bineau (such as ordance or ships). Subsequent to 1915 there was a chief of naval operations who as commander of operating forces required a staff and as adviser to the president was a member of a staff.

The chief of haval operations, appointed by the president from among line flag officers, commanded the operating forces and was responsible to the secretary of the navy for their use, including but not limited to training, readness and preparation for war and war plans. Stationed in Washington, D.C., he also acted as the principal naval adviser to the president and the secretary of the may on the conduct of war. At the outbreak of World War II the president appointed Adm. Ernest J. King as commander in chef of the United States fleet to control and distribute naval power in

STAFF, NAVAL. A naval staff consists of a group of offist delegated to advise and assist a flag officer in the administrain March 1942 when Admiral King became both fleet commander
in and operation of his command. In the saling-ship or and object of naval operation of his commander.

Admiral King, by virtue of his office was a member of the joint cheefs of staff together with multary heads of the army, the joint multary heads of the army, the was responsible for the strategic planning and direction of multary effort Admiral King sat also on the combined chiefs of staff, an organization composed of the US president, US joint chiefs of staff, British pume minister and British multary leaders. This body was designed to unify the war effort of the two Allies

Latson among Vatious commands, an essential function of World War II staffs, was easily maintained between the joint and combined chiefs of staff since the same US leaders sat on both In subordhate echolises there were frequent interstaff exchanges of views by radio, letter and personal meetings. Theatre leaders and their staffs made recommendations based on knowledge dear tived from proximity to the scene of action. Thus, in 1943 when Admiral Nimitz's staff discovered that amphiboious assault against Narru Island in the Pacific was physically impracticable he suggested that the joint chiefs of staff substitute Makin. This was done. Similarly, when US commandes in Philippine waters in 1944 found unexpected enemy weakness and asked authorization or an immediate seizure of Leyte, permission was at once granted

After World War II the title commander in chief United States fleet was abolished, the chief of navial operations retaining the functions of that office. In July 1947 congress passed the National Security act providing for unification of the armed forces under a single civilina secretary of defense. Under this act the joint chief of staff comprised a charman, the chief of staff of the army and are force and the chief of navial operations. In addition there was an Armed Forces Policy council which included the secretaries of defense, army, navy and air and the joint chief of staff. This council advised the secretary of defense on matters of hoad policy relatine to the armed forces.

The staff (although not called such) of the chief of naval operations consisted of a vice-chief of naval operations, an inspector general and five deputy chiefs of naval operations, one each for the fields of personnel, administration, operations, logistics and an

The traditional technical bureaus were retained, the secretary of the navy, assistant secretaries and the chief of navial operators sharing jurisdiction over the bureau chiefs and receiving from them technical advice and logistic assistance. These bureaus were ships, aeronautics, ordanace, supplies and accounts, navial personnel, medicine and surgery, yaids and docks, judge advocate general and headouratres marine corbs

To summarze, the chief of naval operations was a member of the president's military staff. As operational chief of the navy, he was advised and assisted by his staff of vice-chiefs. The bureau chiefs, primarily responsible to the secretary of the navy, were not a staff in the strict sense.

The term naval staff is not to be confused with naval staff corps which are organizations of specialists. In the U.S. navy in 1790 the staff corps were, medical, supply, chapian, civil engineer, dental, medical service and nurse corps Staff corps officers exercised administrative jurusdiction within their specially but only in exceptional instances succeeded to combat command which was the province of the executive or "fine corps" of the navy

the province of the executive of me to object to the province of the executive of me to object to the executive of the execut

Great Britain.—In the British navy the naval staff at the admiratly consists of the chief of the naval staff, who is also the first see lord, the vice-chief of naval staff, the deputy chief of naval staff (art), who is also the fifth see lord, and the assistant chief of naval staff. These officers together with the second, third and fourth sea lords are the naval members of the board of admiralty. These officers are assisted in their duties by the directors and officers of the various staft divisions which include. Inteligence, plans, signal, operation, trade, naval air warfare, naval

air organization and training, gunnery and antiaircraft, torpedo, antisubmanne and mine warfare, navigation and direction, tactual and staff duties and training. The naval staff was organized and embodied within the board of admirally on May 14, 1917

Maval officers serve on the naval staff of the admirally for a period of about two years, after which time they rejoin the fleet. There is, however, a large permanent civil staff which handles the office administration and advises on technical, legal, financial and secretarial matters. By this means a destrable degree of continuity is maintained despite the frequent changes in naval personnel. At the same time the organization is kept up to date with new ideas:

and opmons from sea Outside the admiratly each commander in chief, squadron, division, floulla or base commander is allocated a staff commensurate with the size and importance of the command. Thus a commander in chief of a main fleet or station will probably have appointed to his staff officers designated to perform the duties of chief of staff, captain of the fleet, operations, plans, intelligence, guinery, torpedo and antisubmarine, communications, aft, royal mannes,

eigineering, accountancy, medical, electrical and educational On foreign stations this staff may be augmented by officers appointed to carry out the duties concerned with the logistic support of the fleet. This duty would normally be performed by the admirity on a home station. In addition, it is a custom to allow every admiral in command a personal staff consisting of a secretary and a flag leutenant (A D.C.) who is usually a specialist in communication of the control of the cont

cations duties

The flag officer in command of a squadron of ships is provided with a smaller staff. The staff officers in many instances perform ship's duties in addition to their staff function. For example, the gunnery officer of the flagship is frequently squadron gunnery.

officer on the flag officer's staff

The captam in command of a destroys flotilla or escort group has a staif of specialist officers (i.e., gunner, torpedo and antisubmarine, communications, engineering, avantion, electrical) to assist him in deciding the policies to be employed within the flotilla under various circumstances. The duties of the staff also include assisting individual commanding officers in technical matters regarding repair and maintenance and also in weipon training and practices.

After World Wai I a need was felt for proper training in staff duties so that all officers on staffs would be thinking, planning and

writing on more standardized lines

By 1938 the Naval Staff college at Greenwich was engaged in buning out a number of officers who were trained to be stiff officers and who were possibly capable of reaching the higher ranks of the navy since they would then be able to appreciate more readily the functions of their staffs. The Greenwich course had the added advantage of giving officers an adult education which was designed to assist them in carrying out their duties on an admiral's staff. This staff training was continued, with a short break during World War II, and extended. The royal navy, together with its sister services the army and the royal air force, sends its officers to higher staff colleges where training is given on a higher and more unified level.

To train the best officers the royal navy has always been averse to any idea of a general naval staff corps. Naval staff officers when embarked in an admiral's flagship are considered in excess of complement and do not fall into the chain of command of the ship in which they are embarked. This does not, however, interfere

with their chance of promotion.

STAFFA (Norse for staff, column, or pillar island), uninabited island of the Inner Hebrides, Argylishire, Scotland, 54 m. W. of Oban by steamer, about 7 m. from the nearest point of Mull, and 6 m. N. by E. of Ions. It lies almost due north and south, is \$4 m. long by about \$4 m. wide, and its highest point is 135 ft. above sea-level In the north-seat it shelves to a shore, but otherwise the coast is rugged and much indented with numerous caves. During the tourist season it is visited regularly by steamer from Oban. In section the isle has first a basement of tufa, from which rise, secondly, colomades of basait in pillars forming the faces and walls of the principal caves, and these in turn are

overlaid, thirdly, by a mass of amorphous basalt. On the southeast coast is the Clam-shell or Scallop cave. It is some 130 ft long, and on one side of it the ridges of basalt stand out like the ribs of a ship. Near this cave is the rock of Buuchaille "Her Herdsman," from a supposed likeness to a shepherd's cap), a pile of columns, fully seen only at the water On the south-west sales are the Boat cave and Mackumon's or the Comorants' cave. Fingal's cave, the most famous, situated in the southern cof of the isle, is 227 ft. long On its western side the pillars are 36 ft. high The cave is the haunt of seals and sea burds

STAFFORD (FAMILY) This famous English house was founded in Englind by Robert, a younger brothet of Ralf de Tosiny (Toeni), of a noble Norman house, who was standard-bearr of the duchy Robert received at the Conquest a great fiel extending into seven counties and became known as Robert de Estafford from his is issidence at Stafford castle. With his son the male line became extinct, and his sister's husband, Hervey Bagot, one of his knightly treants, succeeded to the fier in her right (1194), their descendant Edmund de Stafford (that surrame having been assumed) was summoned as a baron in 1299. His son, RALPH, conducted the brilliant defence of Auguillon against the host of France, fought at Creey and in the stage of Calais Chosen a Knight of the Garter at the foundation of the order, he was created earl of Stafford in 355.

His son Huori, who succeeded as and earl in 1372, served in the French wars. From 1376 he became promument in politics, probably through his marriage to a daughter of the earl of Warwick, being one of the four lords on the committee in the Good Parlament, and also serving on the committee that controlled Richard II. (1378-86), whom he accompanied on his Scottish expedition in 1385. He dead next year on playimage at Rhodes. His son, Thomas, the of Buckingham (son of Edward III.), who, on Thomas's death, married in 1398 his brother Edward, but of the 1814 his properties of the State of the State of the State of the State of Suckingham, was placed by his descent and his possessions in the front rank of the English nobitly.

HENRY, the 2nd duke, was attainted in 1483, but on the triumph of Henry VII. in 1485 EDWARD, the 3rd duke (1478-1521), regained the title and estates, and recovered the ancestral office of lord high constable in 1509. He was accused of treason and, after a nominal trial by his peers, was beheaded on May 17, 1521, a

subsequent act (1523) confirming his attainder

HENRY (1501-1563), the son of the last duke, was granted by the Crown some of his father's manous for his support, and, espousing the Protestant cause (though married to a daughter of Margaret, countess of Salisbury and sister of Cardinal Pole). was restored in blood on Edward VI's accession and declared Lord Stafford, as a new creation, by act of parliament. His second surviving son, Thomas, eventually assumed the royal arms, sailed from Dieppe with two ships in April 1557, landed at Scarborough, seized the castle, and proclaimed himself protector. He was captured and executed for high treason. His father's new barony, in 1637, passed to a cadet in humble circumstances, who was called on, as a pauper, to surrender it to the king, which he did (illegally, it is now held) in 1639. The king thereupon bestowed it on Mary Stafford (the heir general of the line) and her husband, William Howard, in whose descendants it is now vested. Roger, who had surrendered the title, died in 1640, the last heir male, apparently, of the main line of this historic house.

of the main line of this historic house.

STAFFORD, market town, county town, municipal borough, Stafford parliamentary division, Staffordshire, England, on the river Sowe, a tributary of the Trent. Pop. (1938) 32,190. Area

7 or sq mi. An important junction on the L M.S. railway and 1321 mi. NW. from London, it is also served by the LNE and GW railways. While largely modernized, it contains a number of picturesque half-timbered houses. The church of St. Mary, once collegiate, with its canons mentioned in Domesday, shows transitional Norman, Early English and Decorated styles. The complete foundation is attributed to King John It contains a memorial to Izaak Walton (q v.), a native. The older St. Chad's (much restored) has good Norman details Since 1909 Stafford has been the seat of a bishopric suffragan in the diocese of Lichfield. The William Salt library, presented in 1872, has many local books and mss.
Stallord (Stadford, Stafford, Stafforde) is said to have originally

been called Betheney from Berthelin, a hermit who lived there In later Anglo-Saxon times Stafford contained a royal mint. It is a borough in Domesday Book, and the chief place in the county The king received all dues, two-thirds as king, the other third as earl of Stafford From the Domesday Survey it appears that the Conqueror built a castle at Stafford; this was destroyed in the wars of the 17th century. The existing ruin of Stafford Castle is that of an unfinished mansion (1810), which replaced the old stronghold. Beyond it is an early encampment, Bury Ring, A charter from John (1206) constituted Stafford a free borough. The staple industries are the manufacture of boots and shoes and

engineering. The town was extended in 1934

STAFFORDSHIRE, a midland county of England, bounded by Derbyshire, Leicestershire, Warwickshire, Worcestershire, Shropshire and Cheshire The area is 1,154 sq ml. The county may be divided into three geographical divisions, north, middle and south Staffordshire, depending on the geological structure. The highest land is in the north Here the southern ends of the Peak folds bring up Lower Carboniferous rocks, with limestones in the north-east and the Pendleside shales and Coal-Measures forming four basins in the north-west and centre The district is drained by the headwaters of the Trent and its tributaries the Dove, Hamps, Manufold and Churnet and shows a diversity of scenery, the limestone hills being domed and treeless, whilst the Pendleside shales form heather-covered moors, and the grit bands have bold scarp faces Axe Edge (1,756 ft ), and the Roaches are the highest hills, being formed by Millstone Grit The four coal-basins are the Pottery, Cheadle, Shaffalong and Goldsitch Moss coalfields. The last two are small and contain only the lowest coal-measures and are no longer worked. The Pottery and the Cheadle basins are more important and contain valuable seams of coal The Bunter sandstones of the Cheshire plain overlap the coal-measures in the west of the Pottery basin.

Middle Staffordshire is a broad undulating plain, occupied by various members of the Trussic series and drained by the Trent The plain is divided into an eastern and a western portion by Cannock Chase, formerly a royal preserve, now an important coalfield concealed beneath a cover of glacial sands and gravel which rest upon Bunter sandstone. The high ground rises to about 500 feet The "Black Country" occupies the greater part of South Staffordshire. Here again the country is low and undulating covered on its margins by the Trias whilst in the middle lies the South Staffordshire coalfield, in which there are several small inliers of Silurian rocks which stand up above the surrounding country to a height of 800 feet. Most of the county is drained by the river Trent, a few streams drain into the Dane which flows into the Mersey, whilst a small area in the west and south-west forms part of the Severn drainage system The only considerable sheet of water is Aqualate Mere on the Shropshire boundary

Staffordshire is an important coal-mining county The Southern coalfield has an estimated reserve of 1,415 million tons and the northern coalfields 4,460 million tons. The latter contains the valuable black-band ironstones which are of commercial importance, and a smaller amount of iron is mined in the south where, however, there are important quarries for road metal.

History and Early Settlement .- Although remains of Palaeolithic man have been found in the Derbyshire caves over the border, no finds are known from Staffordshire itself. Neolithic implements, especially round barrows and Beaker pots of later date are found almost entirely and in fairly large numbers in the

north-east section of the county. In early times this remon must be considered as part of the Peak district of Derbyshire. In the remainder of the county there are isolated finds of Bronze, notably palstayes at Brewood, Biddulph, Rushbury and Stretton, a bronze sword at Alton Castle and a leaf-shaped spear-head at Yarlet. These isolated finds serve to indicate the beginnings of movement along the valley ways and the importance of the roads around the hills into Wales and the west In Roman times Letocetum just south of Lichfield was the most important settlement

In the 6th century a tribe of Angles settled about Tamworth. afterwards famous as a residence of the Mercian kings. Later the invaders advanced beyond Cannock Chase The district was frequently overrun by the Danes, and it was after Edward the Elder had finally expelled the Northmen from Mercia that the land of the south Mercians was formed into a shire around the fortified burgh which he had made in ora at Stafford. The county is first mentioned by name in the Anglo-Saxon Chronicle in 1016

The resistance which Staffordshire opposed to the Conqueror was punished by ruthless harrying and confiscation, and the Domesday Survey supplies evidence of the depopulated and impoverished state of the county The five hundreds of Staffordshire have existed since the Domesday Survey, and the boundaries have remained practically unchanged The shire court for Staffordshire was held at Stafford, and the assizes at Wolverhampton, Stafford and Lichfield, until by act of parliament of 1558 the assizes and sessions were fixed at Stafford

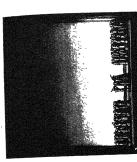

In the wars of the reign of Henry III most of the great families of Staffordshire, including those of Basset and Ferrers, supported Simon de Montfort, and in 1263 Prince Edward ravaged the lands of Earl Robert Ferrers and destroyed Tutbury Castle During the Wars of the Roses, Eccleshall was for a time the headquarters of Queen Margaret, and in 1459 the Lancastrians were defeated at Blore Heath. In the Civil War of the 17th century Staffordshire supported the parliamentary cause, but Tamworth, Lichfield and Stafford were garrisoned for Charles, and Lichfield Cathedral withstood a stege in 1643

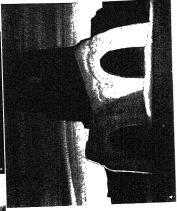

Much of Staffordshire in Norman times was waste land, but the moorlands of the north afforded pasturage for sheep, and in the 14th century Wolverhampton was a staple town for wool. In the 13th century mines of coal and iron are mentioned at Walsall, and ironstone was procured at Sedgeley and Eccleshall In the 17th century the north of the county yielded coal, lead, copper, marble and millstones, while the rich meadows maintained great dairies; the woodlands of the south supplied timber, salt, black marble and alabaster; the clothing trade flourished about Tamworth. Burton, and Newcastle-under-Lyme, and hemp and flax were grown in the county The Staffordshire pottery industry is of early origin, but was improved in the 17th century. It has been greatly extended in modern times

Architecture.-The most important churches are the beautiful cathedral of Lichfield, and the churches of Eccleshall, Leek, Penkridge, St. Mary's at Stafford, Tamworth, Tutbury and St. Peter's at Wolverhampton all of which are described elsewhere. Checkley. 4 m. south of Cheadle, shows good Norman and Early English details Armitage south-east of Rugeley, has a church showing good Norman work Brewood church, 4 m. south-west of Penkridge, is Early English Audley church, north-west of Newcastleunder-Lyme, is a good example of Early Decorated work remains of the Cistercian abbey of Croxden, north-west of Uttoxeter, are fine Early English, and at Ranton, west of Stafford, the Perpendicular tower and other portions of an Augustinian foundation remain Among mediaeval domestic remains are the castles of Stafford, Tamworth, Tutbury and Chartley Beaudesert, south of Rugeley, is a fine Elizabethan mansion in a beautiful undulating demesne In the south-west, near Stourbridge, are Enville, a Tudor mansion, and Stourton Castle.

Agriculture and Industries.—About 75% of the total area of the county is under cultivation, and of this three-quarters is in permanent pasture, cattle being largely kept, and especially cows for the supply of milk to the towns. Staffordshire is well wooded; the National Trust owned 1,964 ac in 1942.

The southern industrial district, the Black Country (q.v.), is

MODERN LIGHTING APPARATUS

 Mezzanine in Roxy theatre with lighting effects that are used to reflect the mood of the stage presentation.
 Roxy theatre switchboard, 8ft high and 22ft long, with over 1,000 switching levers and 500 diamets.
 The meastor room of the Roxy theatre where reacter dimmers and contactor

switches are placed. The reactor plates run up to a capacity of 15,000 watts each. 4 Compact lighting control board for the Wisconsin Memorial Union auditorium. Two matter faders, one on each side, enable the operator to shift at any desired speed from one pre-set to the other.

LIGHTING EQUIPMENT FOR THEATRES

- 1 Spotlight with widely variable spread and soft-edged beam

- 4 Motor-driven autotransformer dimmer, modulite type
- 2 Manual text projector, which there a behave from there to four times as legislat said of an endinary solution and the said of the said and said of the said and said the said and said text of the said text 5 Borderlights are used for tone and blending rather than for sharp definition

the main seat in England of iron and steel manufacture in all its branches It covers an area, between Birmingham and Wolverhampton, resembling one great town, and includes such famous centres as Walsall, Wednesbury, Dudley (in Staffordshire) and West Bromwich The northern industrial district forms the Potteries (q v ), Cheadle east of the Potteries, is the centre of a smaller coalfield; Burton-upon-Tient is famous for its breweries. Chemical works are found in the Black Country and at Tunstall, glassworks at Tutbury, there are also a considerable textile industry, as at Newcastle-under-Lyme, paper mills in that town and at Tamworth, manufactures of boots and shoes at Stafford and Stone, silk and artificial silk at Leek and other manufactures in the county include rubber goods, and motor cars

Communications,-The main line of the L M S railway runs from southeast to northwest by Tamworth, Lichfield (Trent Valley), Rugeley and Stafford This company and the GWR. serve the Black Country by many branches from Birmingham and jointly work the Stafford-Shrewsbury line The L.M S has branches from Trent Valley to Burton-upon-Trent, and from Rugeley through the Cannock Chase coalfields, from Stafford and from Burton-upon-Trent northward through the Potteries, with a line from Uttoxeter through Leek to Macclesfield

The west and north line of the L M S (Bristol-Derby) crosses the southeastern part of the county from Birmingham by Tamworth and Burton with a branch to Wolverhampton The LNE serves Uttoxeter, Burton and Stafford. A considerable amount of coal transport takes place along the canals of the Black Country

Population and Administration.-The area of the geographical county is 1,154 sq mi, with a population in 1938 of 1,483,650 The area of the administrative county is 1,071 sq mi.; population (1938) 749,900 Staffordshire contains five hundreds, each having two divisions. It contains 6 county boroughs and 8 municipal boroughs. The county boroughs are:— Stoke-on-Trent, Wolverhampton, Walsall, Smethwick, Burton-on-Trent and West Bromwich; and the municipal boroughs are .-Lichfield, Newcastle-under-Lyme, Stafford (county town), Tamworth, Wednesbury, Bilston, Rowley Regis and Tipton There were 17 urban districts in 1943, as follows, given in alphabetical order —Aldridge, Amblecote, Biddulph; Berrley Hill; Brownhills; Cannock, Coselev Darlacton Vilamento hills; Cannock, Coseley; Darlaston, Kidsgrove; Leek; Rugeley; Sedgley; Stone, Tettenhall, Uttoxeter; Wednesfield; and Willenhall Other towns are Abbots Bromley, Brewood, Cheadle, and Eccleshall There are two cities in the county, Stoke-on-Trent and Lichfield. The county is in the Oxford circuit, and assizes are held at Stafford. It has one court of quarter sessions and there are 20 petty sessional divisions. The county boroughs have separate courts of quarter sessions and commissions of the peace. The county is in the diocese of Lichfield

Staffordshire is divided into seven parliamentary divisions each returning one member, Burton, Cannock, Kingswinford, Leek, Lichfield, Stafford and Stone The parliamentary boroughs of Stoke-on-Trent and Wolverhampton return one member for each of three divisions, and the boroughs of Newcastle-under-Lyme, Smethwick, Walsall, Wednesbury and West Bromwich each return one member The county and parliamentary boroughs return m all 18 members.

BBRIOGRAPHY.—J. C. Wedgwood, Staffordshire Parliamentary History (1910), C. J. B. Mascheld, Staffordshire (1918); M. Hugbes, The Story of Staffordshire (1924), W. B. Smith, Staffordshire (1915); and the Vectoria County History, Staffordshire.

STAGE, in architecture, an elevated floor, particularly the various storeys of a bell-tower, etc. The term is also applied to the plain parts of buttresses between cap and cap where they set back, or where they are divided by horizontal strings and panelling. It is, too, the floor or platform on which plays are acted, whence the term has come to signify both the theatre (q v.) and the drama (q.v). See also STAGE DESIGN, below. From its etymological meaning of a station comes the sense of a place for rest on a journey, the distance between such places, etc.

STAGE DESIGN. Until about 1900 the pictures created on

to 1900 had made a common possession. The picture of the world within the theatre was invariably dull, without illusion and rigidly painted,-painted, in fact, with the same merciless and metallic precision which led Manet to exclaim before one of Meissonier's paintings of charging currassiers, "Everything is of steel except their breast-plates" Trees stood invariably in regimental rows and their foliage hung in separate parallel layers above their trunks. The walls of hovels or palaces reminded the most careless eye that they were merely painted canvas; the sky flapped, an obviously painted sheet. The ugliness of the total result was all the more glaring because, in an age of realistic playwriting, actors were using every artifice they possessed to make an audience feel that they were Russian or Silesian peasants, Norwegian town councillors, or English clergymen and poets. Every word in the theatre was trying to convince its hearers that what they saw was not actors, but human beings in a world as real as the one they had just left to enter the theatre, that people "were like that"; that life had this significance and that meaning. But everything on the stage reminded the audience that, after all, what they were seeing was a play in a thoroughly artificial place, the theatre, that had no relation to life Even when a poet held the stage the result was equally ludicrous. It was difficult for the singers of Wagner to transport an audience to the beginning of the world, where the gods were deciding the destiny of men, when everything about them seemed an enlarged landscape done in chromolithograph Mary Garden wandered in a park that had neither magic nor mystery, in the supposed gloom of palace halls as bland as lithographs of English country houses, current in the '50s Any symbolism that might have lurked in Maeterlinck's fairy tale of the terror and foreboding of young love was dissipated; and Mélisande's cry "I am not happy" seemed less a comment on the state of her soul than on the preposterous stage settings that surrounded her.

The inadequacy of this type of scenic background, so prevalent at the turn of the century, did not lie alone in its artificiality nor in the fact that it was an obvious and flimsy convention. Artificiality and the conventions of formally painted designs, as proved by the work of Inigo Jones, Bérain and the Bibienas, can breed beauty in the theatre just as easily as the same tradition in the 19th century bred ugliness. The reason for the change which makes painted scenery in one epoch enhance the meaning of the play and in another detract from it, is our changed attitude towards the theatre The creative dramatists of the past 40 or 50 years, whom for convenience sake we may call modern, such as Ibsen, Shaw, Hauptmann, Chekov and Strindberg, Synge and O'Neill, are modern in the sense that one and all they do not regard the theatre as a place of pure entertainment. And they have succeeded so well that though we may still go to the theatre merely to be amused, we also go to watch a play with the same expectation with which we open a novel treating of modern life-in the hope of seeing more clearly into the springs of character, of getting a fresh sense of human destiny

The Modern Scenic Movement.-The blatant dissonance between modern plays that were attempting to reconceive a world and scenic backgrounds that merely reflected the conventions of a purely theatrical theatre, was so preposterous that it could not endure. For that reason, directors of modern theatres in every country in Europe, beginning with Germany, and finally in the United States, enlisted painters or designers to make the world on the stage the world of the play. This is the genesis of the so-called modern scenic movement. It arose, not because modern art already existed, but because it became essential to the theatre in order to quicken the reactions of the audience until the world the dramatist asked them to believe in had the plastic reality of a world before their eyes or the imaginative quality of a poet's dream. The source of modern scenery has not been dogma. It did not arise because Gordon Craig prophesied that only screens could back a stage; modern scenery would have occurred whether or not Craig had ever existed or penned a line. He, however, was one of those who prophesied that a change must come and any stage, generally known as scenery, had no relation to the that stage settings must be designed to interpret the play they feeling for form, colour, composition or light which art from 1850 housed. Every manner and method of modern painting, has, with the aid of some mechanical device, been put to work in the theatre. the plaster dome, in conjunction with the flexibility of incandescent lamps which made the painted sky seem a heaven and filled the stage with all the ambient light of day; the spot-light, manipulated to create the chiaroscuro of Daumier, light mixed with colour in the manner of Monet and Seurat making colour vibrate, and achieving the atmosphere of the impressionists, or enmeshed in gauze, giving the atmosphere of Whistler's nocturnes. Every technique of modern art has been exploited, whether of impressionism, post-impressionism, cubism or futurism However, from the point of view of pictures constructed within the proscenium frame of the theatre, almost every method at one time or another, in the hands of a particular director and in conjunction with the methods of his actors, has succeeded in convincing an audience and projecting the interpretation of a dramatist's ideas

The point needs stressing because the history of modern scenery is usually regarded from the point of view of a mere chronology of begetting, and is continued in the strain of prophecy' A designer reading any of the current histories of his art would feel that the entire problem before him was the choice of a style And the value to him, as a craftsman, of almost all discussions of the subject, is hereby rendered nil The theatre, it is supposed, is about to be re-created, purged of evil, saved and given its final form if he, the designer, only makes the right choice, screens, a stage without curtains, scenery made of nothing but curtains, a circus theatre where the actor can mingle with the audience, scenery that is only light, scenery that is merely symbolic colour, scenery that is wooden trestles, and so on, depending upon which method at the moment has had the latest critical success in Europe. It is essential for the scene designer to avoid this critical approach if he wishes to analyse the basis of his craft For whatever his preferences may be as a painter, he will find that the moment he sets out to design stage settings his problem is everywhere the same He will find the problem of relating a particular play to a particular audience, the problem, as conceived by the director, of how the meaning of that play can be put over the footlights, and dramatized for that audience. His methods will be deduced not from any abstract aesthetics of the theatre but from the exigencies of that particular situation. For not all his convictions as to why imitation and realism was a defunct method prevented George Bernard Shaw from continuing to write plays so provocative that they must be acted in country-house gardens, Salvation Army barracks and physicians' consulting rooms, for which the designer has to build the walls, find the furniture and even evoke the flowers. On the other hand, not all the dogmas in the world as to the value of realism prevented Shaw, or any other playwright, from reconstructing Antony's adventure in Egypt or Adam's adventure in the Garden of Eden, for which there is an equally avid audience, and the designer will have to find a decorative equivalent for the sphinx, or some symbolic equivalent of the tree of knowledge And whether theatre audiences are those of London, Prague, Berlin or Warsaw, the designer will find that they came to the theatre to share experiences that are not their own, so that in the course of a single season the designer may have to help in making plausible the romantic scruples of a Hungarian schoolboy or a Hungarian servant, the feudal scruples of Japanese noblemen, the political dogmas of Slavonic revolutionists, the moral codes of American revolutionists and Russian peasants.

Staging of "The Fathful,"—Some of the problems of semic design as worked out by the present writer at the Guild theatre of New York, although not final in any sense as examples of theatre art, are tyrical of the problems which every stage designer must face in order to evolve design, whatever the pattern he may ultimately adopt. "The Fathful, by Dho Massfeidel, tells the story of 47 Ronin, retailers and henchmen of a Japanese nobleman, tricked by a rival into committing an affront to the emperor's person for which the only explation was suicide; of the voluntary call of these Ronin as partials, and their final triumph over their dead master's enemy It is a poet's celebration of the nobleness of loyalty What is the producer's problem? Obviously something more

than to demand poetic background for a poetic play, because the tale of the 47 Ronin, as much of a household story in Japan as Washington and the cherry-tree in America, is totally unfamilial to Western audiences He can count on no background in the audience's mind But Japan is the background which he must create decisively five minutes after the curtain is up, for the reason is that the unforgivable act committed was nothing more than a mistake in ritual, a failure of ceremonial observance, not to the emperor himself, but vicariously to the emperor's person as personified by his envoy The rigid code of Japanese feudalism is a tradition difficult for Westerners to conceive The danger is that they will find it, if not preposterous, at least not plausible, so that they cannot identify themselves with the hero. The problem here is that to an audience not composed of orientals or members of Japanese societies, the normal reaction would be "Stab oneself because of a mistake in court etiquette? How preposterous! What a trivial people!"

The playwright cannot solve this problem in the many ways that are offered to the novelist, he has no preliminary chapters or incidental comment to prepare the mind of his audience, as his story proceeds, to make them understand the rigid Samuiai code of honour and accept the tragic alternatives imposed on its adherents Aware of this problem, the designer finds, in making his first researches into the field of Japanese costume and architecture, that ritual ruled not only court etiquette but all Japanese life of the period, to the most trivial detail. Everything is prescribed and ordered, the degree to which the head is shaved, and the degree to which the hair is looped forward on the head, the precise way the obs or white silk belt is tied that holds the pleated skirt in place, the length of the sleeves, as well as the cut of the gown. Everything is ordered ceremonial, even the squares of the matting, the placing of the sword in its rack, the one picture niche where the solitary landscape scroll is shown and the way the single group of flowers is arranged under it. There are in the simplest acts, of receiving a friend and taking tea in his presence, countless opportunities of outraging him by breach of etiquette.

In a world of this sort, it begins to be comprehensible that a mistake in court efiquette could involve the death penalty. Hence every effort—and here the producer co-operates—is made to convey the ceremonucusness of the Japanese feudal world, in the gait of the actors, their gestures, their genuflections, the mode of entering or leaving a room. A Japanese is found to train them, he ties every obi, adjusts every costime, este every that and wig The room which is the opening scene of the play is almost archaeling the second of th

On the other hand, once the world of the Samurai is realized, and the tragedy is enacted, there is no further need of such realistic devices. The ragged Ronin wander in the snow, but the snow may be the snow gorges of Japan, painted upon a six-fold Japanese screen, without diminishing either the reality or the suffering of these outlaws Here a deliberately decorative method seems the inevitable choice Japanese landscape is known to Western audiences through the popularization of Japanese prints. A screen setting evokes this purely decorative pictorial tradition and suggests the countryside of Japan far more effectively than any attempt to reconstruct it realistically Thus meticulous realism and deliberate decoration can be employed simultaneously in the same play, and for the same purpose. As pictures the snow scenes are far more effective. But in the theatre the palace scene was far the more important of the two. For if that scene succeeded in conveying Japan effectively to the audience, the world of the Japanese could be taken for granted for the rest of the evening. A white sheet and the shadowgraph of a few pine boughs might have done just as well for the winter hills. This instance reveals how superficial it is to codify stage sets according to

purely pictorial principles

Staging of "Liliom."—Molnar's Liliom presents an analogous problem of transplantation, not from one century to an

other but from one country to another at the same period. The producer's problem in Liliom was, in essence, that his story deals with the creed of a gangster and a "tough" who is fundamentally romantic Liliom falls genuinely in love with the servant, Julie, and evinces a belief in "the eternal feminine" worthy of a latterday Faust. He is transported by the prospect of fatherhood When he stabs himself rather than be captured by the police in an attempted hold-up that fails, his last cry is. "Julie my little girl my little cricket." When, after facing the judgment of heaven and ten years' probation, he returns to earth as a beggar for an opportunity to win redemption, he steals a star to give to his daughter, and then in a moment of evasperation beats her, as he formerly beat her mother The child cries "he hit me but I didn't feel anything—as though someone had stoked my hand . . ." "Nothing has happened" her mother assures her, divining who the beggar is, "it is possible, my child, for someone to hit you-so that you don't feel any pain " Liliom is not forgiven in heaven, he is redeemed on earth by the persistence of human compassion. The beauty of the final scene made the play at the Guild theatre an allegory, the vindication of a romantic faith, and dictated the scenery. The play was some-thing more than the story of a foreign underworld; its realism was made an ironic cloak for poetic truth. Thus the amusement park where Liliom flourished as a bully was made as authentically Hungarian as possible, so that the audience might accept the reality of a romantic gangster and not reject him as a maudlin invention On the other hand, precisely because the play seemed important as an allegory because of its poetic truth, the tawdry squalor of Liliom's surroundings had to be invested with beauty, even the tumbledown shack in which he lived And the railroad embankment, where he attempted his hold-up and met his death, was composed with some of the dignity and severity appropriate to tragedy

Scene 2 represents the park where Lilom falls in love. The point is that, bully, seducer and braggart though he is, he does fall genunely in love. He is transfigured and the moment becomes as beautiful for this Hungaran hoolgan and a kitchen mad as it does for all lovers. Therefore, the park where they meet must be made beautiful. The hour is dusk, when, as Whistler reminded us, "the evening mist clothes the riverside with poetry as a veil, and the tall chimancys become campaniles, and the warehouses are palaces in the might and the whole city hangs in the heavens", the "exquisite hour" as Verlaime calls it. Therefore the problem for a designer was to clothe that park with poetry as with a veil; with tree silhouettes which are hung on transparent gausses; and putting into those tree silhouettes all the grace and timed to arch over young lovers. Had the scene been one of cynical seduction, this quality of tenderness and brooding would have been irrelevant.

Scene 6 represents heaven Liliom sees heaven in terms of the police courts with which he is familiar. He can conceive of no other bar of judgment; heaven is merely the last police court presided over by a police-court judge; the attendant angels are to his eyes only detectives and policemen. The stage directions emphasize the fact by stating that their costume is the usual police uniform Nevertheless, Liliom has died, he is in heaven awaiting eternal judgment. If the play is to be properly interpreted this seat of judgment cannot be the proverbial heaven with a celestial throne. On the other hand, if the allegory of the play is to be made plain it cannot be shown simply as a police court. This dilemma was solved by making the scene as far as Lihom's eye ranged a drab room, with the ordinary judge's bench at one end; but the solid walls ended at the wainscoting and window frames. Beyond that was emptiness; the room sat without walls or roof under a blue sky as illimitable as stage light could make it. By this combination of realism and fantasy, the reality of heaven was established for the audience, and at the same time the fact was made clear that to Liliom its judgments were no different from what he had experienced on earth. These four scenes from two plays entirely different in type demonstrate how contradictions of realism and decoration in stage pictures are determined by

problems of dramatic interpretation and not primarily by pictorial considerations. The picture is a result of a conviction as to what the meaning of a play is and how it can be reflected in pictorial form

The Method of Abstraction .- Settings that eliminate the stage picture entirely are designed for the same reason and by the same process The Tidings Brought to Mary, by Paul Claudel, was played on the same platform for its entire five acts, which according to the stage directions take place in a barn, a farm kitchen, an orchard and a road at the edge of a forest. Fedor Komisarjevsky, the director, chose the unit platform because he felt that the play was mediaeval not only in its story but in its quality It was a mystery, couched in the mystic faith of a truly mediaeval catholicism. A single square block served as a hench and, when it was covered with a formal cloth, as a suppertable and an altar. The orchard became eight nuns clothed in Byzantine splendout, each holding a branch of silver flowers, who stood in a remote semi-circle. The sky behind them at this moment became green to suggest the foliage of out of doors. For the road-side scene at night, the same backdrop became the inky blue of a wintry night spangled with a few stars. And a cold steel-blue light thrown over the platform gave the illusion of winter snow For the miracle the sky blazed forth gold, like the background of a 14th century mosaic, and aureoled the actors The same intention was carried through the costumes many were mediaeval French, but others-those of the father and motherwere clad in the traditional robes of early religious paintings, so that the mother had a suggestion of the Mother of Christ, the father, of one of Christ's disciples, and in its formal grouping, the supper of farewell suggested an apostolic meal

In Man and the Masses, by Ernst Toller, the formal platforms became almost invisible. The settings were made wholly by the massing and the movement of the actors. The human beings on the stage provided all the scenery that was needed, for the play was conceived as an abstract allegory. One leader who tries to limit the workers to the bloodless methods of a general strike, is called simply The Woman. The agitator who incites them to revo-lution is called The Man Though the workers are supposedly in their union hall, their angry indictments of capitalistic society are chanted in unison as a formal chorus. How could this meeting be placed in a realistic setting of an actual union headquarters, without making such formal choruses seem ridiculous? The title literally translated is "mass-man." The force of Toller's conception is his vision of mass-man. The working-men are a single stubborn unit, welded together in resentment and anger, from which only voices of the young and the old emerge to cry, threaten and lament If a group of 30 or 40 actors on the stage are to give this feeling of mass power, they cannot be scattered, they cannot move about much; they must be welded. Hence a stage setting was devised for the drama that was a literal crosssection of an amphitheatre, the players never moved from the spot where they were wedged; they rose with waving arms and clenched fists to face The Woman, who pleaded with them, they towered over her; she was below them, supplicating When this compact mass of 30 actors stood they seemed to represent "the masses", it seemed that they could sweep down on The Woman and overwhelm her. Then The Man sprang out of their midst and slowly backed up step by step to the top of the amphitheatre. As his eloquence grew they swung slowly round, looking up towards him, turning their backs on The Woman as they ignored her pleas. Finally, at the moment when they were won over to a doctrine of violence, they were a solid mass, crouching under him waiting to spring; as he cried "revolution" they took one step up, the only step they took in the entire act, and lunged together like a huge beast, echoing his cry "revolution." Each one had turned completely round during the scene without once moving from the spot on which he or she stood. They remained a mass, and by a single mass movement expressed their change of faith.

Varieties of Interpretation.—The designing of scenery is thus never a purely pictorial problem, it is part and parcel of the act of interpreting a play. Whether a designer chooses abstraction or realism, a picture-stage which imitates the world as we see it in rooms with the fourth wall knocked out into which we peep, modern stage the spectators are looking into a space so shallow or a formal stage which symbolizes the world, is in itself a relative thing The method of design chosen is only good even from a pictorial point of view provided it touches the imagination of an audience, and really convinces it of the truth and reality of the play Setting the play is only part of the process of acting it so as to give it dramatic force, no method, however beautiful it is as a picture, is the right method if it fails to convince an audience; and there are as many types of audience as there are kinds of play No play has only one meaning, it can mean all things to all men The imagination of the director must decide and the pictorial imagination of the scene designer must second him. If you can make your audience accept Liliom's story as a modernistic fairytale, an allegory from the outset, Pitoev's method of presenting it in clear hard formal outline is the right one If the play means more as a story in which the allegory is implicit, then the more realistic method of the Theatie Guild is better; similarly with He Who Gets Slapped. To compare the two, one would have to sit through the two productions as played by two different casts.

There is no one way of producing any play, even classic masterpieces In fact every one, whether Euripides or Shakespeare, has to be constantly re-interpreted, in order to become relevant and remain living. If Shakespeare's characters seem important as figures rescued from an actual historic past then the elaborate and exact costuming of the Duke of Saxe-Meiningen or Henry Irving is not only necessary but effective. To one audience, which conceives them primarily as creatures of Shakespeare's time, the bare boards of the Elizabethan stage will make them live more completely. To another audience, particularly sensitive to Shakespeare's word-magic, formal scenery, even a single curtain, is enough To a German audience, for whom much of the poetry is lost in translation, more pictorial backgrounds are necessary, into which that lost glamour must be projected But to both German and American audiences for whom Shakespeare's protagonists are imaginative figures living in the world of the imagination, they become most real when part of an unreal world, a forest of dyed strips of tapestry or gauze (Barker's production of A Midsummer Night's Dream and Reinhardt's production of the same), or a blood red stairway (Jessner's production of Richard III ), or among golden screens (Craig's production of Hamlet with Stanislavski at the Moscow Art theatre) And if the tragedy of Hamlet begins to seem too remote and archaic to us, we can make him a human being, for certain audiences, by putting him in modern dress. The art of scene designing is a living art because it can find no final formula. It will live precisely as long as it can discover new meanings in every play of every epoch. Scenery is the background of a play, and as such is part of the continuous adventure of projecting the meaning of a play across the footlights, finding, firing, and then fusing the imagination of an audience. And that adventure will always be a different one in every country and every epoch

Structural Innovations.—The technical and structural changes which determine the design of modern scenery are two: first, the modern theatre, in contrast to the 18th century theatre, has become an extremely shallow box, second, that black box can be completely flooded with electric light, modulated and controlled. The theatres of the late 17th and 18th century fixed the architectural type of theatres, which with changes of ornament and the depth and arrangement of balconies is the type still prevalent to-day But there is one vital difference; the proportion of the space occupied by the stage in relation to the space occupied by the audience in the auditorium. The 18th century stage averaged in depth 1 to 11 times the depth of the auditorium pit, and was rarely less than 75 feet. The modern stage, except in opera houses and European state theatres, is rarely more than 1 the depth of the auditorium, and averages at the best 25 to 30 feet.

Moreover the 18th century stage was carefully calculated to enhance painting in perspective. The stage floor sloped up. The side flats receded until the rear of the stage was very near the true vanishing point, so that an alley of trees or an avenue of that any illusion of depth is difficult to attain. In an average production there is raiely more than 8 to 10 ft from the garden wall to the distant mountains, often there can be only 4 or 5 ft from a window to the sky

The early technique of shifting scenery was done by having the side flats on grooved slots, set in pairs, tied to a rod which connected with a series of windlasses in the cellar. At a given moment one turn of these windlasses would shoot the rear flats out like a shutter, and withdraw the front flats out of sight, achieving a complete change of scene with great precision. A beamed gridiron under the ceiling, with another series of windlasses, hoisted and lowered the clouds and the platforms on which gods and goddesses descended Owing to the shallow space of the modern theatse and the suppression of the apron in front of the curtain, the front rows of spectators can see clear to the roof and to the side walls. The modern stage settings therefore have had to become a three-sided box with a lid over the top, when interiors are called for, for exteriors a curved sky, either of canvas or of plaster is used, instead of a sky in flounces as seen in the 18th century theatres There is so little room on the stage for stackmg scenery that most of it has to be broken apart, or unlashed, for each change of scene, and hoisted into the air where it hangs until it is needed again, and as certain sets may be 24 and sometimes 30 ft high they have to be hoisted high enough to be out of sight when not in use Hence the gridiron from which scenery is hung-handling is facilitated by having the lines that haul it attached to counterweights grouped at one side of the stage,-is the most important part of standard stage equipment The opening which the audience sees, the proscenium frame, is in reality a mouse-trap shutter at the bottom of a tall shaft. The average proscenium opening is 24 to 30 feet. The curtain in actual use is rarely drawn higher than 20 ft for exteriors, and 12 to 14 ft. for interiors, the remaining space is occupied by flounces and draperies. And the gridiron must be a minimum of 65 ft. in height; for hauling scenery out of sight, 80 to 85 ft. is better At the Century theatre, New York, it was about 100 ft above the stage floor.

In any case the space behind the stage opening is mainly storage space for hanging scenery in mid-air The place occupied by the largest scene is approximately one-seventh of the total stage space, and the proportion will not vary greatly in American theatres or most commercial theatres of Europe

The system outlined above is not by any means the best either mechanically or aesthetically. It is, in method, as archaic as hoisting sails; indeed the workmen on the stage who shift scenery are known as the crew to this day. The revolving stage introduced by Lautenschläger from Japan was used extensively, and did away with the necessity of a gridiron almost entirely. At Dresden, Linnebach at the State theatre and Hasait at the Opera constructed elevator stages worked by hydraulic power, so that heaviest sets could be set in the cellar, hoisted to stage level and slid into place with extraordinary speed. The cellar being two or three storeys deep, the settings for two or three entire productions could be kept intact indefinitely.

These mechanical marvels have never developed because the economic trend of the time is against them. Land has become too expensive to allow the amount of space and excavation required; rising costs everywhere in Europe make the duplication of any such installation prohibitive. In the United States where a single elevator platform 12 by 30 costs approximately \$25,000 to install, an entire stage so equipped would represent a capital investment that only the very wealthiest theatrical producer could carry. Thus theatres tend to become smaller and shallower and the theatre everywhere approximates to American conditions where everything has to be crowded into a standard building site of 100 ft

Important architectural experiments have been made which aim at changing the conventional "peep-show theatre," as its critics have called it, where we look into a stage picture through a more or less gilded frame Theatres have been projected with the stage columns receded very much as they would in nature. But on the as a formal platform, where the actor emphasized in space, picked

surrounded by them, a sort of electric contact being the goal sought The most notable theatres of this sort have been the projects of the American Geddes, the Dutchman Vanderwelde and the Austrian Stranad Jouvet's platform stage designed for Copeau existed in Paris for a number of years; a circus theatre by Poelzig. "the theatre of the 10,000," was actually built in Berlin, but like Coneau's theatre it was abandoned Quite apart from economic problems, what thwarts the development of these playhouses is the fact that modern playwrights will not write enough plays that can be given in any such manner O'Neill and Shaw, Toller, or Werfel, revert to realism quite as often as they depart from it and write plays which require the three-sided box room or the illusion of distance in an actual world which can only be achieved. in the theatre, by looking through a frame Until modern playwriting achieves some unity of tradition, these formal stages must remain isolated experiments or dreams on paper

Lighting.-The most important effect that the shallow-box stage has had on designing is the fact that perspective planning and painting become preposterous, anything that leads the eye from the front of the stage directly across it to the back wall, makes the eye realize that the picture is only 20 ft. deep. Hence the kind of composition modern scene design employs is not the Renaissance composition of distance into which the eye is led by receding parallel perspective, but distance suggested in the Japanese manner by planes cutting one another like the distant peak of Funyama appearing directly over the brink of a hill The eye, leaping from one to the other, imagines the distance and gets the suggestion of space. Thus a space in modern settings is suggested rather than revealed the base of one column will suggest an entire temple, one pillar in a gloom pierced by a stained glass window will convey an entire cathedral, and because there is no intermediate form between the pillar and the window, the blackness will seem as deep as the nave of a church. Even the window may not be shown but a shaft of light may be thrown from a point out of the spectator's range of vision in order to increase the scale by the same process of suggestion

Light is the scene-painter of the modern theatre; light, not paint, draws the scene, and by varying planes of intensity, models it, and makes the corner of a building solid, a hill remote, a sky infinite though it be only two arms' length from the garden wall If a stage 25 or 30 ft deep is flooded with even radiance, nothing will persuade the eye that it is anything but a shallow box, however suggestive the arrangement of the setting itself may be. Settings are constructed now as in the Renaissance period, of canvases stretched on wooden frames and hinged or lashed together, but the paint on them is a mere preparation for the light to be thrown on. No setting can be designed until one is certain how one is going to light it; the colour painted is conceived as an undertone of what it will seem when lighted on the stage

The railway viaduct in Lilson, for example, if it is to seem massive and menacing must have the light thrown across it, not at it, otherwise it will become flimsy canvas. Thrown from right to left the single pier casts a sharp shadow which gives a sense of solid masonry The whole forepart of this scene must have a different quality and intensity of light from the distant silhouette of factory chimneys. With the right balance of light they will recede and seem distant even though they are actually only 8 ft. behind the arch culvert. And both foreground and background must be properly related to the sky if they are not both to fall

So much for the scene; but there are the actors They must be modelled and emphasized in the areas in which they move; sharply picked out at certain moments, where the action calls for it, at others almost blotted into half shadow, for this scene is one of ambush, of two thieves waiting to rob a cashier, and a rim of shadow into which they can retreat is part of the process of creating the atmosphere of terror and suspense when the crisis comes. Every scene has pools of light waiting for the actors, light which we do not see or know is there until the actor walks into it at a given moment.

out by light, can mingle freely with the audience and is partially other medium in the theatre. We react to it even more quickly than to the actor's voice. In fact it sets the key of our emotions, and determines what effect the actor's voice will have on us. Lights not only paint and model the setting, emphasize its planes, and define its form, light also sustains the mood of a scene, and dramatizes its meaning. Crude or blatant lighting can war against the emotions an actor is trying to convey, and often destroy them entirely, all the more so because the lighting of any scene often does not remain static, but is dimmed or heightened, pulses and fluctuates with the action, like an orchestral score

Change of light alone created every difference essential to the five acts of the Tidings Brought to Mary The park scene of Lilion consisted of two gauzes on which the silhouettes of trees were pasted The entire mood of the scene's poetic dusk was created by a balance of lights In Man and the Masses, the contrast between the mystic dream scenes (not shown) and the sculpturesque force of the mob scenes is entirely a matter of lighting. In the course of the play there were several hundred subtle shifts of lighting timed to coincide with the action of the play. The tree of knowledge in Back to Methuselah was entirely made with light, projected from the tear The sphinx in Peer Gynt became a towering form by the same process. The sacred tree on the rim of the Persian desert in Marco Millions was merely a silhouette on a semi-transparent back-drop But it towered in mysterious majesty because of the way light was thrown upon it, from both front and rear.

The technical basis of this important phase of modern theatre art is the spot-light-in contrast to the flood light-which can be controlled and focussed accurately upon one particular spot. To be effective these spot-lights must be separately controlled so that each can be set at any point of intensity from full to dim and fluctuated back and forth if need be during the progress of the play. Hence the rheostats, or dimmer board, that controls these lights, is to the designer's conception what the central nervous system is to the ideas in the brain. Increased subtlety both in design and control of electric light, and particularly the colour of light, is the key to theatrical design of the future. That must wait not only on the playwright and stage designer, but on the lighting engineer, who, more than anyone, holds the key to the modern

engineer, who, most unit anyone, roots are key to the moura-theatre's destiny (See Theatre Modern Fundacies).

## STAGE EQUIPMENT

The technical equipment of a modern stage consists of two types of machinery. (1) the mechanical equipment used to facilitate "setting and striking," ie shifting of scenery; and (2) electrical equipment to control the lighting of the stage

A house has been described by one modern architect as a machine for hying. A stage has always been a machine for giving plays. Even the Greek stage, usually supposed to be indifferent to scenic changes and scenic effects, was equipped, by the 4th century B.C. and probably earlier, with three standard pieces of machinery. (1) the crane used to lower the deus ex machina (the god out of the machine) from the roof of the palace façade, (2) the periaktoi, triangular prisms placed in the façade of the palace wall, Emotionally we react to light far more quickly than to any revolving on wooden pins and turned in unison, each face painted to indicate a different milieu so that three successive indications of place might be achieved, and (3) the eccyclema, or rolling platform which emerged from the palace doors after the tragic catastrophe, on which the murdered victim and often the aggressor were shown as a tableau

The chef mechanical devices of the theatres in the Middle Ages, the Renassince both in Italy and Blinabethan England, and the European theatres of the 17th and 18th centuries were the trup through which actors appeared and disappeared, often to the accompaniment of effects of smoke and flame, the moving platforms on which Christ was assumpted to the ballowy heaven of an open air mediaeval mystery, or the classic gods descended 20 an open air mediaeval mystery, or the classic gods descended 20 or 20 strong in the glorie that concluded so many 17th and 18th century spectacles and opera, and, when mobile scenery was adopted as part of the technique both of playwriting and play production, the windissess and ropes which hosted scenery out of the way or drooped it into blace.

Until the latter part of the joth century very little had been added to these base tage mechanics. The revolving stage of the Japanese popular theatre of the 18th century was copied by Lautenschlager in Munch in 1898; the State and muncipal theatres of Germany built in the early 1900s operated the traps mechanically, making them elevator stages which rose from a cellar level as needed in addition sliding platforms, each carrying a complete setting, known as wagon stages, were utilized and often operated electrically.

In the United States none of these mechanical improvements was generally adopted, the reason being that the conditions of production remained radically different in the American theatre from those that prevailed in Europe On the Continent theatrical production, particularly in Russia, Germany and the Scandinavian countries, was mainly in the hands of permanent resident companies operating endowed municipal or State theatres which gave a wide repertory of plays ranging from intimate realistic comedies or tragedies to large-scale spectacles and opera. The productions were built on the premises so that workshops as well as a large storehouse were an integral part of the architectural plan, as can be seen in the municipal theatre at Stuttgart with its large theatre at one end, a smaller theatre at the other, and the long façade of the storehouse serving as a connecting link between the two. The complete mechanization of such stages was considered worth the very large investment required in order to facilitate the giving of a different play every night of the week. This type of elaborately mechanized theatre is still standard in Europe,

as exemplified by the theatres recently built in Goteborg and

Malmo, Sweden In the United States, particularly after the decline of the local stock company at the end of the 10th century, the individual company, usually assembled for the occasion, was the producing unit, and much of its income was derived from touring on "the road" through all the principal cities and many of the smaller ones of the entire country For this reason the mechanical arrangements of the stage remained primitive. Until late in the 10th century the rigging of most stages was exactly like that of a ship. The ropes needed to hoist the scenery up and down were attached to a fly gallery and tied to the belaying-pins on a pin rail, which was an almost exact counterpart of the pin rail of a frigate. Massive or solid scenery was not often built, the entire system of scenic construction consisting of breaking the sets into units not more than 5ft. oin, wide so that when the settings were dismantled they could be slid through a baggage car door, its standard height being about 6 feet. The American theatre remains very largely an itinerant theatre to this day, the production being assembled usually in New York, then taken for a "tryout" on "the road," then brought back to New York, and, after a New York run, if it is a success, taken on tour again Instead of being designed and built for the dimensions of a permanent playhouse, it must fit the variable stage dimensions, often exiguous, of any number of theatres.

American theatres have therefore generally been built to rent to travelling productions, either for a percentage of the boxoffice gross or for a fixed guarantee per week, and it has been

the rule to provide as limited mechanical equipment as possible in order to reduce the landlord's overhead expense. The lighting system in these theatres is usually old-fashioned and even primitive, and controls the minimum of apparatus, a few overhead borders and footlights. The company must bung in all its lamps cables and "dimmer boards," or rheostats, needed to control them. The only mechanical improvement that became common is the substitution of the counterweighted lines operated from the floor. which replace the dead pull of the old rope sets worked from the fly gallery. The houses built in the last century usually had a single trap, known as the Hamlet trap, placed so that Ophelia could be conveniently buried. The trapping of commercial stages is not uniform, and it is under these conditions that even the most modern scenic productions have been made, and to meet these conditions that they have had to be designed and devised Where revolving stages or sliding stages are needed and used, as is occasionally the case, they also have to be carried on tour and assembled for each opening performance

Before the deflation of 1929 very few technically adequate theatres had been built, the Century Playhouse, since torn down, a few theatres such as the Martin Beck theatre and the Guild theatre in New York being the exceptions, and a few new opera houses such as those in Chicago and San Francisco. In the main, however, the professional theatres in the United States have either rudimentary or madequate in equipment, and except for the houses on "the road" large enough to house musical comedete on tour the stages are too shallow and lack the off-stage space needed to manipulate efficiently and without great waste of time and labour the scenery and properties used during a typical performance.

The technical equipment of American theatres has recently improved due to the fact that they are now being built on college and university campuses for a continued repertory of student productions, and so begin to approximate the rational layout of the repertory houses of Europe Notable examples are the new theatre at Stanford university, the Wisconsin Union theatre at Madison. Wisconsin, opened in 1939, and the auditorium at the University of Indiana, Bloomington, Indiana, opened in 1940, as well as such small theatres as the recently opened theatre at Amherst and the large playhouse projected for Dartmouth college In these theatres, not restricted by the size of a conventional city lot, and where the cost of land is not an item of initial expense, stage dimensions are ample, the stage running from 35ft to 40ft in depth and 70ft to 80ft in width from wall to wall, they are provided with an adequately high gridiron, approximately 70ft, and a complete counterweight system as well as a stage floor that can be trapped over a third of its area. In addition there are workshops where an entire production can be fabricated and painted At Stanford, at Wisconsin and at Bloomington two auditoriums are provided a large auditorium with a seating capacity running from 1,300 to 3,000 which can be sub-divided by curtains for smaller audiences, and a smaller theatre for more intimate or experimental productions At Bloomington and Wisconsin an electrically operated forestage has been provided which can at the touch of a push button be dropped below auditorium level to become an orchestra pit, raised above auditorium level for formal productions, making a forestage for an Elizabethan production if needed or dropped to auditorium level to hold additional seats

The funds available for the building of these theatres, running from approximately \$50,000 to wer \$75,000 are, even so, not ample enough to provide for any further mechanization of the stage equipment, such as electrically driven revolvings stage to wagon stages; even on a college campus the additional offstage space is rarely available which would be required to house these wagon stages when not in use The plans for the Dartmouth theatre, however, call for two such reserve wagon stage spaces, and the prize winning design of the William and Mary competition (see Theatre Arts for June 1393) also indicate their use

The more important technical equipment of the modern theatre remains the lighting control system, and the distinguishing feature of a modern production is the subtle variations of light which accompany and dramatize the dramatic action of the play. The need for these changes, known as "dims," was felt centuries before the mechanical means for their effective use had been invented The dialogues of Leone di Somi, a Mantuan stage director, written shout 1565 (see Appendix B, Allardyce Nicoll's The Development of the Theatre, and edition, Harcourt, Brace and Company, 1937) contain the following indications of how variations of light emphasize the mood of the scene

"Now it has been a custom, both in ancient and modern times, to hight bonfiles and torches in the streets, on the housetops and on towers, as a sign of Joy, and hence arises this theatical convention— the mutating of such festive occasions. The lights are put there for no other purpose but to imitate, in the very first scene, this mood of

garety"
"I suppose, then, that these lights would not appear in a tragedy"
"Perhaps they would not be so wholly out of place even in such a play Oute apail from the fact that there are tragedies with happy endings, we note that nearly all tragedies open in a happy strain, and consequently it will not be unfitting to arouse the mind, so far as we may, to this happiness, although disasters and deaths are to ensue later I remember once I had to produce a tragedy of this kind During all the time when the episodes were happy in mood I had the stage brightly illuminated, but so soon as the first unhappy incident occurred—the unexpected death of a queen—while the chorus was engaged in lamenting that the sun could bear to look down on such evil, I contrived (by prearrangement, of course) that at that very instant most of the stage lights not used for the perspective were darkened or extinguished. This created a profound impression of horror among the spectators and won universal praise

A device for dimming the candlelight of the period can be found in Nicola Sabbattini's well-known treatise. The Practice of Making Scenes and Machines in Theatres, printed in 1638

Di Somi continues

"It is a natural fact-as no doubt you are aware-that a man who stands in the shade sees much more distinctly an object illuminated from afar, the reason being that the sight proceeds more directly and without any distraction toward this object, or, according to the and without any distraction toward this object, or, according to me peripately theory, the object impinges itself more directly upon the eve. Wherefore I place only a few lamps in the auditorium, while at the same time I lender the stage as blight as I possibly can

Thus the general scheme and balance of our stage and auditorium lighting was anticipated by nearly 400 years. But the subtleties of modern stage lighting were not finally outlined until Adolphe Appia wrote his epoch making work, Die Musik und die Inscentering (1899), and described in detail a typical light plot for a production, never made, of Tristan und Isolde, in the appendix to the volume.

"Fitture of the stage at the rise of the curtain A great torch at stage centre. The somewhat narrow stage space is filled with enough the stage centre. The somewhat narrow stage space is filled with enough beliance of the torch and above all without dimming the shadows which this source of light casts. The forms which demarate the stage setting are seen only harply. The quality of the light veils them in an atmospheric blur. A few barely visible lines in the stage setting machact the forms of trees. Gradually the eye becomes accusiomed to

this, above, it becomes aware of the mass of a building in front of which one perceives a terrace. "During the entire first scene Isolde and Brangaene stay on this terrace and between them and the foreground one senses a declivity, the forms of which one cannot identify clearly When Isolde exthe torms of which one cannot identify clearly When Isolde ex-tinguishes the torich the entire setting is enveloped in a monotonous half-light in which the eye losse itself without being arrested by a single definite shape Isolde, as she flies towards Tristan, is enveloped in mysterious shadow which intensifies the impression of death that in mysterious saacow wanch intensines the impression of ceata that the right haid of the stage has already induced in us. During the first existacy of them encounter both remain on the terrace. At its cidinax (page tray, plano 8°, 10° and oron Menn's perceive that they come toward us imperceptibly from the upper terrace and by means of a barely noticeable ramp reads a lower platform further in the foreground ramp of the platform, the ramp leading from the terrace to it and another incline which leads to the foregrant of the Stage trainfy. make an uneven terrain on which the glowing dialogue of the scene that follows takes place

Then, when their desire is sufficiently appeased, when a single idea possesses them and when we become increasingly aware of the death of time, only then do they reach the foreground of the stage death of time, only then do they reach the foreground of the stage where (pp 336-37) we percave for the first time a lench that avants where the property of the property of the state of the stage still more uniform in that. The structural forms are blotted out in the shadow of the background and even the different planes of the stage floor are no longer visible. The stage floor are no longer visible. The stage floor are no longer visible. The stage floor are no longer visible of the stage floor are no longer visible. The stage floor are no longer visible and the stage of the stage floor are no longer visible. The stage is the stage of 
eniolded by the world about them During Brangaene's song the light grows still dimmer. Even the figures of the actors not made the property of the actors not made and the actors are more recorded and the actors are more recorded and the actors of the actors and the actors are more recorded and the actors are more than a superior and the actors are actors and actors and actors are actors and actors actors and actors and actors actors actors actors and actors a contact with the world once again, challenging Melot, who betrayed him, to a duel

pot is veiled from the dawning day and remains soft and shadowy

the bench at the foot of the terrace

These ideas again anticipated the technical means of accomplishing them It is only in recent years that lighting control systems have been perfected to the point where such fluctuations of atmosphere and light on the stage, to the accompaniment of the changes of dramatic mood and dramatic movement of the script, can be accomplished

In order to understand this it is important to realize the elaboration of the lighting apparatus needed to light a play and its disposition. The footlights and borders which used to be the principal source of illumination are now unimportant adjuncts of lighting equipment. The focusing lens' spot light with coloured mediums of either glass or gelatin is the essential unit. They are usually assembled on two upright pipe battens on either side of the stage, known as the "light tormentors," and are also hung from one or more pipes overhead, the total often reaching 60 or more spot lights. In addition, in order to illuminate the actors without relying on bright foots which, if used with sufficient strength to light the actors' faces invariably cast distracting shadows on the scenery back of them, spot lights are located in the ceiling beam of the auditorium so that the angle of throw is approximately 60° and hits the actor head-high from the front of the forestage to a point within 6 or 8ft upstage of the proscenium where the overhead and tormentor lights can illuminate him These lights are focused in groups to cover various acting areas. and their colour is determined by the nature of the scene whether daylight or night, whether they are projected to illuminate the actors or give colour and tone to the scenery They are then successively brought up to a given point of intensity, ie "dimmed up," or "dimmed down" to a lower point of intensity in overlapping groups, making a light plot which approximates in general scheme and intention Appia's light plot quoted above

The greatest flexibility of control is therefore essential, and the control hoard-commonly called the switchboard-temains the nerve centre and the most important single piece of apparatus on the modern stage. Up to recent years the standard rheostat or dimmer consisted of a wound core of resistance wire through which the current was shunted. Thus, when the light was dimmed a major portion of the current was turned into heat The control was entirely mechanical, each dimmer having a dimmer handle which operated the dimmer from full to out. A certain number of these dimmers could be geared together on a shaft and worked by a master handle. However, as there was a limit to the number that could be geared together without creating too much friction or making the mechanical control extremely difficult to operate, it was usually impossible to select all the lights needed for a particular change and operate them together in a mechanically efficient

way One either needed several operators or often, on a large switchboard, an operator with the reach of an orang-utan For it must be remembered that in the dimming changes of a modern light plot the light changes start with 50 or more lamps each set at different degrees of intensity-some may be full, some only half bright, others only a quarter up, etc. The change does not take them uniformly either to full or out. Those half-way up may only come down a few points in intensity; others may go to full out. others may come up in the opposite direction from nearly dim to nearly bright And it is the drawback of the mechanical gearing of dimmer handles on a single shaft that it is impossible to gear them until they are all brought to the same level, so that the task of stopping some when they reach the various predetermined levels of intensity is an almost impossible one to achieve accurately by hand

This has been made possible recently by several improvements in the lighting control system. The first is a reactance dimmer in the form of a thyratron tube which directly regulates the voltage of each citcuit. The second is a theostat known as an auto-transformer which automatically transforms the voltage of the lamp to correspond with the desired intensity, the contact being a carbon or copper brush actuated by a motor. Both these dimmers have a variable capacity, the auto-transformer having a wider variable load. The old-fashioned resistance dimmer of 1,000 watts had to be connected with a lamp on lamps of a cold 1,000 watte capacity of a lamp of 10 with 1000 transformer dimmers will take a lamp or circuit of 4,000 watts reacting the production of the connected at the product of the connected at the product of the pr

The reactance type of dimming control, though it is in process of being simplified, is much more complicated in wiring layout. more expensive both in initial and installation costs, and occupies more on-stage space than the auto-transformer type. The operating mechanism on the auto-transformer control board consists of a series of potentiometers which actuate, on a 24-volt circuit, the motors attached to the auto-transformers. The control is through a series of small handles over a graduated semi-circular arc which set each circuit at any point between full and out. Without affecting the set-up of the lights then on, a second set of handles controlling these same circuits is pre-set at any number of other points of predetermined intensity from full to out, and the change from the first pie-set to the second is made electrically, each circuit stopping at the point indicated and pre-set. Two master handles are provided which are electrical master controls so that. as on the board at the Wisconsin Union theatre, any of 56 circuits can be connected with one master, the remainder with the other master, and the light change be made on these two sets of selected circuits simultaneously at different speeds either in the same or opposite directions, ie either from full to out or from out to full, or to any number of pre-selected intermediate points of intensity for each circuit. The system thus gives complete control of any number of lighting units in any number of possible combinations in a way that no mechanical system of dimmer control is able to achieve This lighting control system in one type or another will undoubtedly become standard in the near future

It has the further advantage that the control wires can be extended to a point in the auditorium or in the projection booth at the rear of the auditorium, and a portable dimmer board be connected there so that the lights can be as effectively controlled from the auditorium as from backstage if the occasion requires.

An additional feature of modern lighting equipment is the lighting of the cyclorama. The illusion of depth and space in an open air sky is best achieved by a plaster dome, but as this is a heavy and elaborate piece of construction, and requires a great deal of off-stage space if it is not to interfere with the exigencies of scene shifting-more space than can usually be given to it or paid for-a cyclorama made of a textile is the usual substitute. This is a cylinder of cloth or canvas laced to a semicircular pipe above and below, and lighted from overhead and below by lights in parabolic reflectors with glass mediums that are spectroscopically accurate to act as light primaries-red, blue and green. By combinations of these at various intensities in conjunction with the proper painting of the cyclorama itself the colour of the cyclorama can be changed through almost the entire range of the spectrum. As painted canvas is very much affected by changes in humidity and can rarely be made to hang properly, the better practice is to use dyed cotton velour; and in order to facilitate changes of setting during scene intermissions, the up- and down-stage arms are made in the form of travellers, the velour being heavy enough to be drawn back without settling into wrinkles.

The mechanization of the stage for scene shifting seems to offer no further possibilities of practical development differing from what has already been achieved. Future technical developments

will undoubtedly be in the electrical field, the development of low voltage high wattage lamps, increased flevibility of focusing lens units, increase in the range of variable load of rheostats and added flexibility of electric master and sub-master control

BBILIODRAFIV —These devices can be studied in ditail in Gustave Chen's Historie de is mue on sche dass le biddier retigues; françoi du moyen age (1995) and Le hove de conduste du régisseur et le 1997 (1995). ## DEVELOPMENT OF STAGE LIGHTING EQUIPMENT

The first authentic description of artificial light as an integral part of a stage presentation is by the Italian Seito who placed candles and torches behind flasks of coloured water, the light being projected through holes in the scenery. He also used pans and trays as reflectors to intensify the light, but one can magnie that the resulting illumination was never objectionably bright. Even in the early covered theatres the chief light sources were torches or pine knots, open lamps with floating wicks browning vegetable or animal oils, and candles of wax or tailow. "Paid-do's theatre" in Italy and "Black Frais Tim" were the first of these indoor theatres and the first indoor productions in England did not take back cell 11 × 50.

The removal of the theatre from the open air into buildings was the first active force to bring about better artificial illumiation. Ingo Jones brought the Italian theatre influence to England and used the proscenium arch. Gold decorations were applied to the theatre inteneors reflecting light from huge clusters of candles. These were hung from the ceiling in a corona above the stage, and supplied all the general illumination. Even with candles, all the writers of the time referred to the highting as "brilliant".

In 1628 Joseph Furtenbach described the use of oil lamps and candles as "floats" or "footlights," as well as "wing lights he latter being now known as "borders." In 1775 when David Garrick placed a row of candles below and in font of the stage, masked from the audience by metal screens, they were an innovation in stage lighting. Not till the 18th century did oil lamps generally replace candles The John Street theatre in New York, erected in 1767, was illumnated by candles for 30 years

The invention of the Argand lamp in 1783 and the use of camphine, kerosene oil and other higher grade illumnants brought a fat superior light to the theatre. The new lamp, which was a simple oil and wick combination provided with a glass chimney, was the first important scientific advance in light sources in 4coo years. For the first time the illuminant was enclosed rather than being an open flame.

These lamps gradually supplanted the candles Lamps hung in clusters from the ceilings and projected from walls, balcomes and boxes. They were used as footlights, borderlights and wing lights Despite the improvements, there was still only sufficient illumination to make the actors and scenery recognizable

Then came gas. In 1781 William Murdock of England claimed a patent for its manufacture, and in 1803 F A Windsor completed the first theatre installation in the Lyceum theatre in London. In 1796 it was used in Philadelphia for exterior illumination, and in 1816 a complete gas lighting system was placed in operation in the Chestnut Street Opera house of the same city Gas was manufactured on the theatre premises for the theatre only An installation was, therefore, an expensive affair, and gas did not come into general use before 1850.

All of the original gas burners were open farmes or flames burning in open glass chimneys But in 1886 the Welsbach incandescent mantle was invented which increased the efficiency many times. They were used in borders, foots, wings, and bunch lights continuing the old conventions

Gas for the first time permitted the control of all the lights on the stage from one central location Elaborate systems were devised with mains sometimes more than ra" in diameter, and thousands of feet of feeder pipe, both flexible and rigid The Lyceum theatre in London and the Boston theatre in America were two of the first to be equipped with these new controls which were called "gas tables" The first electric control boards were fashioned after these gas tables. They were located near the prompter who could reach a master valve controlling the entire layout In addition to the master there were series of individual dimmer valves, and on some boards flash buttons by means of which spurts of flame could be made to give quick bursts of light

Chief among the defects of this system was the 118k of fire Many theatre fires of this time were started by the blazing spirit wads on long poles used for lighting gas jets among the scenic pieces Dancers with their thin costumes were sometimes set afire by the footlights Because of these dangers, code regulations were established which fixed the position and number of burners in various locations, and made compulsory the use of guards and

scieens over open flames

It became the custom at this time to dim the lights in the auditorium during the play, for at last the theatre had discovered that contrast between light and darkness was as important as light alone for visibility and maintaining interest

Gas lights also left their impression on the scenic design and painting for many years to come The light source was not small nor bright enough for small individual units, and the old-fashtoned borderlights, footlights, and wing lights were retained, altered only to accommodate the burners replacing the oil floats, chimneys and candles

Henry Irving experimented with effects of realism, using individual lights to achieve a more plastic illumination and devising an arrangement for drawing thin coloured silks or screens in front of others. He also started the use of sectionalized strips and borders-later employing spot lights-and thus increased the flexibility of existing apparatus. At this time also the cyclorama made its appearance, a piece of equipment still most useful on the stage

In 1816 the calcium light or "lime light" was invented by Thomas Drummond, and by 1860 had come into general use in the theatre From this unit came the common expression, "in the limelight" which is frequently used today This light source was extremely white and concentrated and therefore could be used behind a lens or in front of a parabolic reflector as a spot light. The apparatus was used to "follow" characters about the set and in a few instances for general illumination of the stage. It required the constant attention of an operator

The beginning of electricity in the theatre was the invention in 1808 of the arc by Sir Humphry Davy, who had also experimented with incandescent lamps as early as 1802 However, this apparatus, although invented before the "lime" lights, did not come into use till many years later. Frequent adjustment was necessary as the carbon was consumed, but the arc was a great advance over the calcium light. Two types of units were built around this source. One used a parabolic reflector behind the carbons, the other was equipped merely with hand operated shutters. The first device was designed in 1846 and used by M J. Duboseq and M. Foncault in the production of The Prophet at the Paris Opera Five years later M Duboseq also developed a lightning machine of a type still used today, a rainbow projector, and a luminous fountain-all built about the arc as a light source,

In 1878 Paul Jablochkov introduced his Jablochkov candle, two vertical parallel sticks of carbon separated by a layer of insulating compound. In 1879 the Bellecour theatre in Lyons, France, installed 52 of them But this method never came into general use for it could not compete with the incandescent lamp invented

by Edison in 1879

This invention brought to the theatre for the first time a clear, relatively high powered, easily controlled light source. For the first time there was light which could be used as a plastic medium, coloured, varied in form and intensity, used in ways which had never before been possible. Wagner in his operas had suggested possibilities in the use of light which stimulated the minds of the producers. He created a demand for technical developments which now began to look possible. Qualities of light were avail-

able to those who would use them, and theatre lighting as an art had arnyed

But the invention of the incandescent lamp alone did not immediately bring modern stage lighting to the theatre. However, its advantages over the older types of illuminants were recognized almost at once, and the change-over was more rapid than it had been with any other type of lamp. In 1880 and 1881 a series of experiments in the Paris Grand Opera resulted in the first theatrical installation of incandescent lamps. The greatest impetus was received from a theatre at the Electrotechnische Ausstellung at Munich in 1882 Incandescent and aic lights were used for audito turn as well as stage lighting, and units on the latter were equipped with remotely controlled colour screens. The tracker wire mechanical method was used for this colour changing and still is

The first completely electrified theatres in Germany were the Landestheater in Stuttgart, the Residenztheater in Munich, the Staatsoper in Vienna, and the Staattheater in Brunn-all in 1883. The Savoy theatre in London and Bijou theatre in Boston installed electric lighting in 1882 The first New York theatre to be equipped was the People's theatre on the Bowery, in 1885 In 1882 a congress of theatrical managers assembled and issued a formal report tayouring the illumination of halls and theatres by means of electricity In 1871 this new method was so well established that a law was passed prohibiting the use of gas in all theatres of Prussia

The original electric incandescent lighting units were footlights, borderlights, and wing lights, following the old conventions Arcs were still used wherever concentrated light sources were necessary. The only bulbs available were of the carbon filament type which gave a relatively dull glow of a definitely orange colour.

Gradually, however, materials other than carbon were discovered and osmium, tantalum, moulded tungsten and finally drawn tungsten were used in filament constructions. The use of nitrogen and later nitrogen and argon in the bulbs further increased the efficiency and decreased the size of the lamps Today, with coiled and coiled-coil filaments, gas filled bulbs, and heat resisting glass jackets, 500-watt lamps only 13in, in diameter are in general spotlight service, and 5,000-watt lamps, although much larger are not uncommon

With new light sources available, equipment was developed to use them more effectively Steel MacKaye, a producer and actor, designed the modern effect machine as well as many other mechanical contrivances for the theatre Mario Fortuny developed the Kuppelhorizont or dome, still the most perfect means of simulating natural or spectacular sky and background effects. He also developed a system of lighting named after him which utilized reflectors of coloured silk placed behind the lamps to tint and diffuse the light. These silk panels were movable so that the colours could be changed and the illumination softened

David Belasco and his electrician, Louis Hartmann, abolished footlights—a suggestion made years before by Henry Irving and began the use of individual sources from the auditorium and above the proscenium for acting area lighting. By means of these instruments as well as special reflector borders and baby lens spots they developed a standard of realism now in general practice in theatres throughout the United States In Germany Lennebach, Hasait and many others made more contributions to the technical development of the theatre. They invented the rolling cyclorama and made up elaborate systems of light control. The Fortuny system was discarded and used only in rare instances

Today the development of smaller lamps with hard glass jackets and concentrated filaments, and new types of reflecting surfaces have made possible the design of two new types of spotlights. By reducing the diameter of the lamp bulb and using a Fresnel or stepped lens, an instrument having a high efficiency and giving an even field with soft edges, useful for acting area lighting and easy to blend into a general effect, has been developed. The second type of spotlight differs entirely from this, the light from the lamp being gathered and redirected by a reflector rather than a lens

An ellipsoidal reflector has the valuable characteristic of re-

directing light which is generated at one of its conjugate focithrough the other This is the principle of the ellipsoidal reflector spotlight. A lamp with tubular glass tacket and concentrated filament, generally of the base-up burning type, is placed with its filament near the focal point within a reflector. A gate or aperture is placed between the reflector and the conjugate focal point and "filled" with the reflected light. One or two lenses acting as an objective then project an image of the aperture on the field to be illuminated. In this way fields of even intensity are produced, the beam may be shaped by means of shutters, iris, or other controls at the aperture, hard or soft edges are possible through focusing of the objectives, and efficiencies comparable to those of the Fresnel lens spotlight are obtained

spotlight are obtained.

The two above properties of spotlights have to a large extent. The two above present groups of the properties of the spotlights, and the spotlights, three other types of lighting equipment are widely used in stage presentations. First are the striplights—really the first form of apparatus as the old wing or borderlights were stips. The latest development in striplights is, the individual were strips. The latest development in stringings is the individual reflector spin which each lamp is placed in a spin reflector equipped with either a coloured glass roundel or a gelatin, or glass colour frame. Floodlights are specially shaped reflectors for individual lamps. They are made in narrow beam or wide beam types and accommodate.

Into are made in marrow beam or worde beam types aim accommonates a small or large lamps. Wide angle floodlights are used for illuminating back drops and cycloramas, and, in the US, are matte finished ellipsoidal refectors Banks of them equipped with three or more filters can give effects which simulate any degree of sky colour from midday to midinght including the brilliant hours of sunset and dawn

Special effects, the fourth class of lighting equipment, often are built about the spotlight as a base, but they may include anything from painted ranbows and moving clouds to water inplies of cut glass strips, a burst of fireworks, or a waving flag The effects are generally painted on mica discs enclosed in a sheet metal protective housing and driven by electric or clockwork motors. These "effects" are placed in front of spothghts, an additional lens being added to each to further concentrate the light, and objective lenses project

each to further concentrate the mages of the moving discs.

As opposed to the complicated design of these "projection effects"

As opposed to the complicated design of these "projection effects"

This apparatus is very old is the simplicity of the shadow projector. This apparatus is very old in principle but the form now used in stage work is the Linnebach lantern—named after Adolph Linnebach, the designer. It consists of a deep box painted black inside and surrounding a concentrated filament lamp or arc One side of the box is open, and over this is placed the slide carrying the design to be projected. Because the lamp filament since carrying the design to be projected. Because the lamp nament on arc has a definite size, sharp projections such as are obtained with lens units are impossible. But very wide areas can be covered at relatively short projection distances, and, especially for silhouettes of skylines and crude outlines, this method has no equal

of sylms and crude outlines, this method has no equal.

In step with improvements in equipment has been the development of new colour medias. Fortuny and other of his contemporaries used coloured sliks and reflectors for tuning the light. I tump dip appeared after the invention of incandessent lamps. Today sheet gelatin is still probably the most videly used colour medium. If is a svallable in large sizes, a great variety of colours, is mesupeare, and most of the colours are relatively last. Horst are constantly being made to in-

crease their permanence

crease time permanence wery unsatisfactory in damp chimates as it also below the readily and proceeds to "melt". In any climate after being subjected to heat from lamps for several hours it becomes very buttle and tends to shrived Acetates, such as celluloid, are much the fire hazad precludes their use Gelatin may be ignitted but supports combustion only with difficulty, and tends to smoulder statier. than burst into an open flame

Cellophane has been used with a great degree of success in recent years. It is available in 11 colours besides clear, black, and two de-grees of clear diffused It is thinner than gelatin, is not greatly affected grees of clear diruses. It is immer than glean, is not greatly succeed by dampness, and supports combustion only with difficulty. Some of the colours are quite fast, but others rather unstable, and the limited colour selection is, of course, a great disadvantage.

From many standpoints glass is the ideal theatrical colour medium

From many standpoints glass is the fideal theatrical colour medium despite its weight, intuital cost and fragility. It has come into use only recently and more because new equipment required it than because it was developed to a new degree of perfection. "Gelatina" burned out with alarmare rapidity when used in front of high powered hight came into use with their greater light outputs and concentrated beams, new colour filters had to be found at once. Coloured sheet glass in both "flashed" and "type" forms was available, but non eit reaked glass in both "flashed" and "type" forms was available, but non eit reaked in the standard of the standard o

ditions Glass is not the perfect colour medium. It is fragile, heavy and expensive. Its colour range is limited, and sheets of glass often and expensive its colour range is imitted, and sheets of gass often vary in colour and transmission by as much as 50% from one end to the other. The field of plastics at present seems to promise a great advance in colour control in the theatre. But as yet there are no transparent materials which are available in heat resisting quality But one day in the not too distant future we may expect a material which can be used without a stiffening frame to support it, one which is impervious to heat or moisture, available in a multitude of fast colours It will be light yet sturdy, and less expensive than glass filters It is not too much to expect

For the remote control of all the old gas lighting equipment, the gas table had proved very satisfactory. In the first switchboards only intensity control was thought necessary, although colour controls had already been included in many of the previous gas installations nada already been included in many of the previous gas invaluations. The first electric dimmers were water barries with two metal plates put in a weak solution of brine. One plate rested at the bottom of the barriel, the other could be reased or lowered, thus varying the restance of the circuit by varying the amount of brine between the plates through which the current had to flow. These units were expenses the country of plates through which the current had to flow. These units were ex-tremely unsatisfactory as the water evaporated rapidly, the heat, if the barrels were overloaded, produced a vile smelling vapour, and the settings for any particular lamp intensity were never twice the same

settings for any particular lamp intensity were never two crites are resistance wire tapped at a number of points, these taps hency connected by wires to the points of a todary switch. By turning the switch the resistance in the circuit could be varied at will. The reswitches were located on the stage floor. Because the resistance to current flow uses energy which, is transioning into heat, the coals content flow uses energy which, is transioning into heat, the coals current flow uses energy which is transformed into heat, the coils became hot, especially when overloaded—and for that reason were dangerous. A large number of wires leading from the control switches to the coils were also necessary, and this was eliminated by the re-sistance plate dimmers next developed.

In this type the resistance wire was laid out on a plate, either itself in this type the resistance wire was fact out on a place, enter rises an insulator or coated with an insulator, and heat resisting compound. The switchpoints were connected with the wine. The entire assembly was coated with more heat resisting material until only the contact surfaces of the switchpoints were visible. The tapping arms were provided directly to the resistance block. This type of control unit is

The most obvious fault of the resistance control has already been mentioned—that energy is used in reducing the current flow and is then dissipated in heat. This fault was recognized as early as 1890 and in 1896 a reactance type of dimmer bank was installed in the Earl's Court theatre in London. Here a double reactance with one

Earl's Court theatre in London Here a double reactance with one oil slipping in and out of the scond was used to contiol each circuit, alternating current being used rather than direct. The plan worked Court of the country of the c

and not current regulators

The most modern types of alternating current controls are the auto-transformer dummer, and the electronic tube and reactance circuit The first is manufactured in sizes up to 5,000 watts for single phase loads and up to 10,000 watts for three phase loads

The latest development in theatrical intensity control equipment is

the electronic tube and reactor circuit, and, still more recently, electhe electronic tube and reactor circuit, and, still more recently, elec-tionic tubes which themselves carry a considerable load current by means of these devices switchboard sizes have been tremendously re-duced, and a panel the size of a moderately large radio receives is now sufficient to control the lights in an entire theatre.

sumerent to control the ignits in an order treature.

Swotching and dimming equipment have been improved and reSwotching and dimming equipment have been developed which permit the instant switching of a large number of controls by means of a single master lever, or allow an operator grad-ually to change the lighting from one predetermined setting to another, some units dimming, some brightnems, but all in proportion to the

individual readings

As has been mentioned previously, tracker wires and mechanical line movements are still the standard means of remote colour control in Europe In the U.S., self-synchronous motors and electromagnetic in Europe. In the US, self-americaness motors and control gentlem that such as the control gentlem that same service. The former permit an operator at the central control panel to move colour frames or lighting units themselves in exactly the same way in which he manupulates levers and dais. Only electric circuits connect the control and the highting equipment—there are in moying cables or pulleys. Electromagnets control and with the control show movements.

STAHL, FRIEDRICH JULIUS (1802-1861), German ecclessastaal lawyer and polituian, was boin at Munich on Jan 16, 1802, of Jewish parentage At the age of 19 he entered the Lutheran Church He was professor of law at Wurzburg, and of ecclessastacal law and polity at Berlin

Stabl early fell under the influence of Friedrich von Schelling, and at the latter's mussience, began in 1827 his great work the Philosophie des Rechts mach escalachtlicher Anualta (an historical view of the philosophy of law), in which he breas all law and political science upon Christian revelation, denies rationalistic doctrines, and as a deduction from this puniciple, maintains that a state church must be strictly confessional. This position Stabl further elucidated in his Der chistiliche Stade und seru Verhalinss sum Denimus und Judenthium (The Christian State and Its Relation to Deism and Judaism).

As synodal councillor Stahl made use of his influence to weaken the Evangelical union (i.e., that compromise between the Calvinist and Lutheran doctrines which is the essence of the Praisant Evangelical Church) and to strengthen the influence of the Lutheran Church (cf. De Luthersheck Kurche wide Pulmon, 1859). Frederick William IV supported Stahl in his seclesiastical policy, and the Prussan Evangelical Church would probably have been dissolved had not the regency of Prince William (afterward the emporer William 1) supervened in 18-8

Stahl retired into private life and died at Bruckenau on Aug 10,

1861
STAHL, GEORG ERNST (1660-1734), German chemist and physician, was born on Oct. 21, 1660, at Anspach He was graduated in medicine from Jens in 1684, and became court physician to the duke of Weimar in 1687.

From 1694 to 1716 he held the chair of medicine at Halle, and was then appointed physician to the king of Prussia in Berlin, where he died on May 14, 1734

In chemistry he is known chiefly in connection with his doctrine of philogation (see CIRMSTRY History of Chemistry), the essentials of which, however, he owed to Johann J Bocher (1635-1632) He also propounded a view of fermentation which mosome respects, resembles that supported by Justus von Liebig 150 years later.

He was a firm believer in animism In his youth he believed in alchemy, but later he warned against its frauds. As proof that metals do not "ripen" into gold in the earth, Stahl cated the fact that British in was the same as when exploited by the Phoenicans He observed that acids are of different strengths, that the basic component of common salt differs from that of potash, and he recognized the particular nature of the earthy constituent of alum.

Among his students were Johann H Pott (1692-1777) who improved the manufacture of porcellan, and Andreas S. Margarfi (1709-1782) who discovered sugar in the beet. Stahl was a prolife writer, using an extremely difficult Latth. He edited Becher's Physica Subcieronae in 1702, and added his Specimen Becheronaum, in which he expounded at length his own views of condustion which were first presented in his Zimotechema Industrial (1697). His chief medical treatise was Medica Vera (1708). His principal chemical work was Fundamental Chymine (1723)

See R. Koch, essay in Bugge's Das Buch der grossen Chemiker (1929). (R E. O.)

STAHLBERG, KAARLO JUHO (1865—1923). Fundish statesman, horn on jan. 28, 1856, began his public career by holidis alternately university and administrative posts. He then became a member of the diet in 1904 and of the Finnish government in 1905, but resigned in 1907 and was appointed a professor of administrative jaw in 1908.

At the outbreak of World War I the government was Finnish in name only, being composed entirely of Russian officials. Stablberg was then president of the diet and had to act as the chief public representative of Finnish opinion.

He firmly withstood the increasingly oppressive tendencies of

the imperial Russian government. After the Russian Revolution of 1917, Finland became an independent republic, and in 1919 Stahlberg was elected to the presedency. He withdrew from the candidature for the next presidency after his term of office ended in 1924. He stood as a candidate in 1931 and again in 1937, but he was not it-elected. Stahlberg became prominently known as an expert on administrative law.

He retired from political life in 1937 and died Sept. 22, 1952, in Helsinki. Fin

STAINED GLASS, a term that is generally understood to refer only to glass windows that have been coloured by such methods as the fusion of metallic oxides into the glass, the burning of prement into the surface of white glass, or the joining of white with coloured pieces of glass.

#### ORIGINS

The origin of stained glass is obscure. It probably came from the near east, the home of the glass industry, and mosaic windows of glass set in plaster work, which is known from the 17th century in Egypt and elsewhere, are probably of great antiquity. But it is not likely that the art goes farther back than the glass century, it is doubtful if before that time glass was made in a sufficient variety of colours to suggest and produce coloured designs.

The art would most naturally spread first to Italy, and Venice may have been a centre as early as the 10th century. An Italian panel in the Victoria and Albert museum, tentatively ascribed to the 14th or 14th century, is fully Italian and Romanesque in style.

and suggests a native tradition

Actually the eathest reference to starned glass in the accepted sense of the term (that is, windows not merely coloured, but the control of the term (that is, windows not merely coloured, but he control of the coloured windows that the cathedra and redecented it with windows representing various stories (Richer, vol. ii, lib. 3). An earlier reference, in a givine century life of St. Ludger, certainly relates to coloured windows, but it is not clear that they were pertoonal. Male gives, as the eathest mentions of leading, a reference to the Miracles of Saint Benost where it is related that in the last years of the 10th century the church of Fleury-sur-Loire was set on fire and it was feared that the leads of the windows would be melted.

Which are the earliest windows extant is a matter of dispute, but the evidence, both literary and stylistic, seems to favour certain figures of prophets in Augsburg cathedral, which may date from the middle of the rith century.

### TECHNIQUE

A stained-glass window is a translucent mosaic held together by lead, that is the simplest conception of its technique. Actually other considerations come into play in the design and execution of a window. The lead is not merely a connecting medium, but in all good design plays a part of its own, it outlines the main constituents of the design, giving definition and rhythm to the masses of colour.

From the account given by Theophilus, a very accurate notion can be derived of the technique as practised when the art first came to its perfection in the rath century. The general scheme for the glazing of a church was, of course, the care of the clerce, and it may be assumed that the artists among them, the illuminators, would prepare the first drawings. One such sense of drawings, the Guthlac Roll, is preserved in the British Museum (Harley Roll, Y 6). But the actual cartoon for the glass was drawn on end of a whitewashed board supported on irestles. The vacant space at the other end was used for laying out the glass and for the general business of glazing.

The cartoon was marked to indicate the various colours, and the next step was to shape a piece of glass to the outline required by the design. This was done, firstly and roughly, with a hot iron and then more carefully with a tool known as the "grozing iron," aft piece of iron with a notch at one end, rather like a modem spanner. This must have been a slow and laborious process, but the grozing iron seems to have continued in use until about 1500.

when the modern method of diamond cutting began to be employed The next step, in a fully developed stained-glass window, was to paint the glass with details which the bare design of glass could not give At inst the use of paint was confined to an opaque brown (grisaille, q v), used, not as colour, but as a means of outlining the design in further detail, reinforcing the effect of the leads This pigment consisted of powdered glass mixed with a metallic oxide (probably iron), to which was added sufficient gum to make the mixture adhere. If "high lights" were desired, the whole surface of the particular piece of glass was covered with a thin coating of this paint and the lines scratched through with a pointed stick Shading effects were produced by stippling with a brush The glass, having been painted, was next fired in the kiln, to fuse the enamels to the glass. In mediaeval times the glass was fired in a pan, which was filled to the top with alternate layers of glass and whiting When the glass was fused sufficiently, it was brought out and cooled and then rearranged on the glazing table The next step was the leading This was (and still is) done by means of strips of lead, in section like the letter H, but with a thicker cross-bar to represent the "core" of the lead; the upright strokes represent the "tapes" At first the leads were cast, but in the 17th century the lead vice was introduced This is a kind of mangle, with two toothed wheels like coins with milled edges, between which a strip of lead is squeezed, the soft metal emerging in the form already described Sometimes the wheels had the glazier's name engraved on them, which thus became impressed on the lead as it passed through the machine, and these names are occasionally found on old leading When the leads, cut to the required length and shape, had been inserted between the pieces of grozed glass, they were next soldered together at the points of junction, and cement or putty was rubbed into the crevices between glass and lead. The window was then ready to move into place, where it was fixed by means of leaden strips soldered to the leads and attached to iron saddle-bars let into the masonry, Larger windows were made in smaller units and these units fitted into an iron framework or "armature" which itself often formed a geometric design contributing to the general effect of the window.

From the 12th to the 15th century the technique of stamed glass remained practically unchanged, though one minor innovation had a great effect on the character of design. This was the invention, early in the 14th century, of a yellow stain derived from a solution of silver It formed a very thin film on the glass and was therefore very transparent; on clear glass it varied in tone from pale lemon yellow to deep orange; but it could also be applied to blue glass to produce a brilliant green. Its effect on design was far-reaching and will be noticed when we come to the history of the craft. In the 16th century the technique of glasspainting became more scientific; the glass itself was thinner and smoother and more transparent, two layers of different colours could be put together to produce a third colour; if these layers were fused together, one layer could be ground away or "abraded" (and by a later process "eaten" away by fluoric acid) to give delicate effects beyond the reach of a leaded mosaic. Finally, towards the middle of the 16th century, the art of painting in enamel on glass appeared, perhaps as a result of economic causes which made a scarcity of pot-metal Hitherto glass had been coloured throughout its substance and was known as "pot-metal," though to obtain sufficient translucency in a dark colour like ruby the glass was "flashed," that is to say, clear glass whilst still pliant was dipped into molten coloured glass, and so received a translucent film of the desired colour. But now ground glass was mixed with various metallic oxides (copper for green, cobalt for blue, manganese for purple, and so on) and the design was then painted on to a clear sheet of glass and fused on For some time this technique was continued with the old technique of leaded pot-metal; but in the 17th and 18th centuries the old technique disappeared, and the art of stained glass was virtually dead.

# HISTORY

Eleventh and Twelfth Centuries.—The windows at Augsburg, ascribed by Fischer to the middle of the 11th century, have already been mentioned. To the end of the 11th century belongs

a window at Le Mans (France) painted with the Ascension For the 12th century we have in England a figure from a Tree of Jesse in the minster at York, and at Canterbury there is a magmificent series representing the genealogy of Christ which may be dated about 1180 At Chartres there are more important and extensive examples-in the west window is a Tree of Jesse design which is undoubtedly the best surviving stained glass of this century, also the beautiful figure of the Vugin and Child known as La Belle Verrière Other considerable specimens of 12th century glass exist at Angers, Saint Denis, Châlons-sur-Marne, Bourges, Strasbourg, Potters and Le Champ (Isère) The earliest of these windows, such as those at Augsburg and Chaitres, are strongly Romanesque in character The windows at Canterbury come at the end of the Romanesque tradition. They still preserve the monumentality so characteristic of Romanesque design, but the figures are far removed from the agorously schematic treatment of the Augsburg prophets, there is the first flush of humanism in their bold features. There is a sense of movement in their limbs; a sense of vigour in the formal draperies. The colouring of this Canterbury glass is still typical of the 12th century, the bare flesh is cut in pink glass, whilst the rest of the design is a quet harmony of blues, pale green, white, brown and yellow, arranged in fairly broad masses with no effort towards "jewellike" quality. The architectural settings are rudimentary, in most cases representing a simple column on each side of the figure, with an arch spanning the head

It is probable that most of the early windows were of the singlefigure, monumental character of the Augsburg and Canterbury examples But about the middle of the 12th century a new type of window came into being which consisted, instead of a single representative figure, of a medallion (or several medallions) painted with pictorial subjects, such as incidents from the life of Chust, or from the life of some saint. This change was accompanied by various subsidiary developments. The necessity of telling a story in a series of medallions led to the decorative arrangement of these medallions within an "armature" or iton framework which was itself a subject for pattern, and very beautiful designs were evolved, showing a skilful counterplay of circles, lozenges, quatrefoils and squares, with their appropriate borders and interspaces This development in its turn necessitated larger windows and this necessity had a profound effect on the development of Gothic architecture itself. A third development was in the actual colour of the glass The pictorial treatment called for a more detailed and more varied play of colour, and the technical resources of the glass-maker were equal to this demand. The result was that kaleidoscopic or jewel-like glow of colours with which stained glass is always popularly associated. It is in glass of the early 13th century that this property is supremely evident

Thirteenth Century.-With these early 13th century medallions we first become fully conscious of the part played by the actual painting in stained glass It is true that the earlier figures had a broad effective scheme of drawing, but with the 13th century medallions a fine dramatic sense of line was developed and continued in force throughout the century. And with the sense of line came that superb sense of dramatic composition illustrated in so many of the medallions of this period at Canterbury, Lincoln, Chartres, Sens, Bourges, Le Mans, Rouen, Cologne, Marburg and Klosterneuburg (near Vienna). The highly stylicized motives of the decorative borders of the 12th century were no longer in keeping with this dramatic mode, and as the century advances we accordingly get a naturalizing of these motives. The formal acanthus leaves of classical inspiration give place to more natural plant motives, to scrolls of oak and vine; these coil with a more organic and vigorous movement, until eventually, in the 14th century, the artists begin to copy directly from their own observation-from the ivy and the wild strawberry.

Towards the last quarter of the 13th century, a greyer mood seems to have descended on our glass-panters. It may be that they were required to give more light in the churches, or that the supply of ruby glass, always somewhat precarious, gave out Whatever the reason, there developed in the latter part of the

ight and early 14th centuries the technique generally known as groutle painting. It implies the use of large earses of clear quarties patient in black or brown enamel with simple and unobtrusive patterns of folage. Grissulle work at this period is of two knods it may consist of geometrical patterns of quarries, often outlined in coloured bands, on which are painted designs of folage, often imitation of a trellised plant, or it may be used in combination with subject medallions. The best instance of this latter method is perhaps seen in the wandows of the Chapter House at York, which, though now much decayed and obscured, are supreme examples of grissulle work.

These characteristics of 13th century stained glass are general wherever the main stream of Gothic art (a.v.) flowed. Distinctions of nationality need not, and indeed cannot, be made. In point of time the medallion windows at Canterbury perhaps come first, then, closest in time and style, come the similar windows at Sens, Chartres comes next and is very impressive in its quantity and scale, at Bourges and Rouen there is glass very similar to that of Chartres; the glass at Lincoln and Beverley in England must be placed somewhere before the middle of the century But back again in France we find a more distinctive school developing in Paris during the second half of the century, in connection with the building of the Sainte Chapelle and the extension of Notre Dame. The distinguishing feature of this latter style was the general use of a background of trelliswork in blue and 1ed glass, which, in the mass, has a rather unpleasant purple effect. This style scarcely penetrated to England, though an example may be seen in the east window of the south transent of Christ Church, Oxford,

Fourteenth Century.-Midway in the 14th century comes the Black Death, and this catastrophe marks the end of the pure Gothic tradition, in this as in all other arts. Its most marked effect was perhaps reflected in the break-up of the inter-community of Christian art No doubt other forces, economic or political, were operative too; but the disorganization caused by the Black Death among artists and craftsmen all over Europe resulted in the formation of more limited and more local schools. Onward from 1350 the styles of England, France, Austria and Germany diverge more and more from each other. And within all these countries the local differentiations between various centres are often very marked. The disorganization not only affected traditions, but even more so technique. It seems that the ability to manufacture some of the brilliantly coloured kinds of glass was lost at this time, never fully to be recovered until the 19th century There was also a Cistercian ban on pictorial windows, which no doubt had some influence in this direction, during the 14th century But the glass-painters were not slow to react to the new situation; the invention of yellow stain early in the century had provided them with one new resource; and the growing taste for line design, as witnessed in the grisaille glass already mentioned, led to the full exploitation of clear white glass. When once the use of white glass had been forced on the glass-painters, its aesthetic value was appreciated It may be also that the resultant effect on the lighting of the churches was appreciated, and that the glass-painters began consciously to aim at a clearer effect Architectural developments kept pace with, and even aided, this changing colour-scale. The windows grew higher and wider, the tracery more intricate, demanding of the glass-painter an effect that was not too heavy for the expanse to be filled, or too clumsy for its delicacy.

Further developments were due not so much to economic factors as to a change in spirit. The rath century saw the full emergence of that movement towards humanism which had found its protagonist early in the 21st century in St. Prancis of Assist. The tendency towards naturalism which we have already seen creeping into the decorative motives of stained gass was a far wider phenomenon, and involved all art and literature. The new spirit of Pranciscan naturalism only manifested itself in plasture at by slow degrees, but it culminated in the Renaissance. It involved a transformation of Christan iconography, and the glass-painter, along with other artists, now deserted the fixed types of early Goldic art for the living types before him. Sub-

jects are now given a contemporary setting; for his figures, his costumes and his architecture the painter looked around him and found models before his eyes. A playful freedom of line gradually developed, as the brush-stroke grew lighter, it grew easier. The features are rendered with more grace and verve; there is almost an excess of curve and curl in eyes and lips and locks. An individualization of the features begins to creep in; we begin to feel the presence of real people, friends and contemporaries of the glass-painter, no longer abstracted, no longer idealized The folds of the garments lose their angular restlessness and sweep and sway in graceful curves. We get, too, the entry of fashion The garments in the 12th and 13th centuries are formal and of classical derivation, except in so far as they are ecclesiastical or military. They continue to be somewhat non-committal during the first half of the 14th century, but with the growth of naturalistic treatment and the revival of figure-subjects we get the unmis-takable evidences of contemporary fashions. The representation of costume then becomes a matter of course, and is of great assistance in the precise dating of stained glass

But the most typical and expressive development of ornament is seen in the anony. This form of architectural ornament no double originated in the 12th century, when an architectural unti-generally an architectural control of the co

Fifteenth Century.—With this development of the architectural features of stained glass ornament is perhaps bound up a curious retro-Teatures of stamen glass ornament is permaps bound up a comous retro-gression during the 15th century—the abandomment of natural plant motives for stylicized diapers. Artists forsook the carefully observed tuy, oak and vine, and introduced instead such dreary motives as that usually described as the "scaweed pattern"—an clongated, shapelessly indented leaf, generally painted in reserve on a blue or ruby glass, and seemigly kept as "stock" to be used whenever the design required an indeterminate background. It was a step toward that still more slipindeterminate background. It was a step toward that still more slip shod expedient—the stencilled diaper background of the 16th century The borders, which had always been an integral part of stained glass design, develop in conformity with the general trend. But their aesthetic function becomes less obvious and they gradually loss decorative value.

In the zath century the bodder had been the essential framework of the design, enclosing within its definite pattern the otherwise unconfined design. In the 13th century the border existed as a foil for the sequence of separate designs. Then, in the 14th century, when the subject-panel became solated from its background, the border became a purely decorative feature, contributing a separate unit to the general sthetic effect; in the 12th century the border framed the design assentice sheet; is use tran cantary the border trained use usergue—in the 14th telegraph the frame of stomework, its naturalistic form satting efforts of the contract of the contract of the contract of the efforts of the contract of the contract of the contract of the stonework, and providing, as it week, a transition from one to the other. In this role it naturally tended to become more formal in character. Already in the 14th century the typical border of creeping foliage had been varied with alternations of devices such as crowns, foliage had been varied with afternations of devices such as crowns, chalices, heraldic badges, grotesque annuals, small figures of angels, etc.; an exceptional example is to be seen in the famous Bellfounders' window in the north aisle of the nave, York minster, where the border consists of bells (outer lights) and musical monkeys (centre light). The 15th century saw some recovery of the sense of colour. Coloured life is mentally saw some recovery or the sense of colories of colories glass of a variety of colories, but too even and flat in tone to be quite satisfactory, became available on the continent and was largely imported into England. Alteady in 1408 the east window at York master, made by John Thornton of Coventry, is full of a new vitahly aming it. The covenants for the execution of the glass in the Beni-champ chapel, Wanwick, which are dated 1447, specifically provide for glazing the windows "with Glasse beyond the Seas, and with no Glasse of England; and that in the finest wise, with the best, cleanest and strongest glasse of beyond the Sea that may be had in England" This window was carried out by John Prudde, no of the greatest of English glass painters, and the result is versatile in the extreme, the colours, jewelled and counterchanged to the utmost limits of ingenuity, blazing with the greatest richness imaginable.

In Germany also, the development was in consonance with the richness and complexity of late Gothic art in general, and there the develop-

ment may be particularly associated with the name of Hans Wild, whose principal works date from about 1470 to 1480. His most famous window is in the cathedral at Ulm, and shows great boldness and original lantasy in the use of foliage motives. The window becomes a

original fantasy in the use of foliage motives. The window becomes a futurisant trelliswork of flowering plants and pinnacles in the depths of which the human figures tend almost to disappear. One characteristic of this period is the development of heraldry in glass. We have practically no knowledge or records of the use of heraldry in stance-glass windows previous to the right century, though there are three 13th-century shields in the apse windows of Westminster abbey which serve to indicate an early use of heraldic glass. We know from records that these shields were originally placed in the aisle windows, which were of grissalle. But the particular circumstances which brought heialdic glass into general use are hardly consistent with the spirt of early Gothic art. One of the characteristics of the 14th century is the introduction of the personal element into the windows century is the mitoduction of the personal element into the windows Donois began to desire their potrraits within the design of their window, memorials to the immediate dead began to assume a representation of the mode and technique of plass painting at that time forbade it. The shield of arms had therefore the very definite use of identification but it was soon realized that herathicity and an asthetic value of its own, or rendering of the formal patterns of the shields, and the bullancy doubly attractive in this personal emblem. The ground of the shield, which was suitably filled in with a diaper pattern, gave the glass painter an invention of decourse motives. The technique of Sentiching A design in available of the contraction of the contra opportunity to exercise his stat in utusawork and his returns in invention of decorative motives. The technique of scratching a design with a point through a dense ground of colour, always a pleasant endique in glass painting, was encouraged by this development. The glass palitier kept pace with the heraid, and did not heastate to attempt the utmost elaboration of curved shaled and exuberant mantling With the Renaissance hetaldic glass took on a more restrained appear-With the Renaissance netatine glass took on a more restained appear-ance—at least, in England, where the common use of the garter and the wreath tended to confine the design within sober limits. Elsewhere, the wreath tended to comfine the design within sober limits. Elsewhere, especially in Switzerland, heraldic glass became, during the course of the 15th and 16th centuries, the most typical use of glass painting

the 15th and 16th centures, the most typical use of glass painting. The 15th century saw a great growth and intensification of the 15th and 15th an formed all over Europe, and patitularly in the great ecclesiastical cities. In England, for example, definite schools can be associated with York, Coventry, Canterbury, Winchester, Oxford, Gloucester, Wells, Lincoln, Nowanch and Westmanger. Norwich and Westminster

The different styles are not always easy to distinguish, and the "schools" are rather in the nature of empirical groupings based on the

density of distribution

Toward the end of the 15th century England suffered a general invasion of foreign artists and craftsmen, a growing influx that reached its culmination early in the next century with the arrival of Toringiano and Holbein At this time, in the Netherlands, the art of stained glass had reached a development which, in accomplishment and modernity, was far ahead of the insular style in vogue among English glass painters. The wool and cloth trades flourished in spite of the wars The new wealth to some good purpose, and thus they made the z5th century an age of church building and charatable foundations. And these merage of church budding and charatable foundations. And these inst-hants, moreover, were men of some culture, whose business had characteristic or the contraction of the contraction of the the Netherlands. When, therefore, they required glass for the beau-tiful furnished clumches which they began to construct in various parts of the country, they demanded glass in keeping with their luxinous and the country of the contraction of the contraction of the country that the country of the contraction of the contraction of the answer to the demand these mes enew series and, in accordance with the regulations, established themselves within a recognized stanctury such as the liberty of St. Thomas in Southwarfs, and assumed English names As time went on, they became a menace to the existence of the London company or guild of glazlers, and a continual series of dis-putes between the guild and the foreigners marks the beginning of the 16th century But the proper tradition of glass painting was entirely lost. In the middle ages stained glass thrived as an art subordinate to or in community with, architecture With the Renaissance, and the shifting of the dominant emphasis of artistic effort from architecture smitting of the command, emphasis of artistic earls of an acceptance to painting, the glass spinter found himself in a dilemma. He had to adapt his art to the new conditions, or suffer from the general neglect of arts subordinate to architecture. He attempted to save himself by adopting the aesthetics of painting, and the history of stained glass henceforth is the history of this false steps and of all the disastnous consequences

Sixteenth and Seventeenth Centuries,-But while this false aesthetic was developing, there grew up in France and the Netherlands a full-blooded Renaissance style of glass painting which makes the first half of the 16th century a distinctive epoch in the history of the art. It is a development of the pictorial treatment of the windows on the largest possible scale; the window is regarded as one large canvas;

the intersecting mulhors are ignored. On this canvas the coloured glass the intersecting millions are ignored. On this canvas the colouted glass is spread in generous masses and heightened by all the resources of line and shade. The windows gleam with everything that is rich and oinate in colour, design and subject. The glass is tim, but this fault is counteracted by the breadth of the treatment. The Netherlandish type is well represented in England by the work of imported artists, type is well represented in England by the work of imported artists, of whom Banard Flower is the most important. This artist came, have been supported to the state of the window for Henry Uffis chapel at Westmanster, and was entrusted with the contract for King's College chapel, Cambridge, but deed before he had completed more than four of the windows. It is probable that among completed more than four of the windows. the work which may be attributed to Flower are the windows of Failthe work which may be attributed to Flower are the windows of rain-ford church in Gloucesteshine, perhaps the most complete unit of stained glass remaining intact in England King's College chapel, be-gun by Flower after designs probably by the Flemish artist, Diuck Vellert, was completed by a mixed company of English and Flemish

In France, Rouen was the great centre of glass painting, and that city still offers an incomparable display of the glass of this period, though many other towns, such as Evreux, Châlons-sur-Marne, Dieux, Inougo many other towns, such as Evreux, Chaions-sur-Marine, Dieux, Beauvas, Auch, Troyes and Montimorency, are famous tor their windows. In the Netherlands, the most important windows of this period are found in Antwerp, Hoogstraten, Biussels, Liège and Amsterdam, while the windows at Gouda, panted by the brothers Dirk and Waite Cabeth and their pupils, toward the end of the 16th century, are of extraordinary range and completeness In Germany important schools existed at Strasbourg, Augsburg, Munich, Freiburg-im-Breisgau, Nuremberg, and above all at Cologne, the general character of all of which was not essentially different from that of the dominant Flemish or French type In Italy the period is mainly associated with the name or riench type. In Italy the period is mainly associated with the name of Guglielmo de Marcillat (1467-1529, sometimes erroneously called William of Maiseilles). Windows known to have been made by him exist at Arezzo and Rome, and a very typical example from the cathedral of Cortona, dated 1516, is in the Victoria and Albeit museum cathedral of Lortona, dated 15th, is in the Victoria and Albeit museum At Florence, where there are also important earlier windows in the cathedral which are said to have been designed by Ghiberti and Donattello, other windows in the style of Marcillat may be seen in the church of Santa Croce The building of the cathedral at Milan caused an important school of glass parning to develop there, and the work of Cristoforo de Mottuos and Nicolo da Varallo carried out during the second half of the 15th century is of great beauty. The Milan school continued in full activity during the 16th and 17th centuries In Spain, especially at Seville, León and Avila, magnificent windows of this period exist, but they are in all cases the work of Flemish glass

In the 17th century we find the highest level of glass painting in Switzerland, though actually that level had been surpassed in its own country during the 16th century, when Holbem and Burgkmair were leading designers of the panels typical of that country. But the real leading designers of the panels typical of that country But the real significance of Switzerland in the history of glass painting is that their significance of Switzelland in the history of glass painting is that their alone was evolved an appropriate technique of neamed painting. For various reasons of a social kind, glass painting in that country had further of the people, and a panel for the window of a room was as natural, and even more usual, than a picture for the wall. Glass paintings thus became intimate and portable—a mid of Kleumadare comparable to the development of Kleumplainté in sculpture. Within the limits of this littleness, the art of enameling glass developed an appropriate technique. It was, indeed, the technique of painting translucent painting—but then the Swiss panel was in all essentials a painting. To the same category belong the roundels painted in transucent painting—out then the owiss panel was in an essentials a painting. To the same category belong the roundels painted in grisalle which were produced in large quantities during the first half of the 16th century. In these types of glass painting the specific problems of distance and architectural harmony did not enter into the

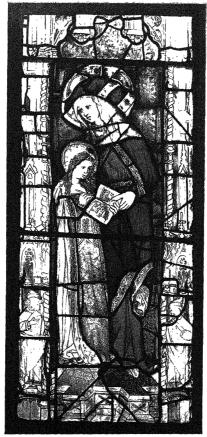

problems of distance and architectural harmony ded not enter into the question; even ything was made for nearness and nutimacy. And on this scale stained glass was imaginopriate, ungainly and without effect glass paintings of the 16th and 17th centures, which illustrate glass paintings of the 16th and 17th centures, which illustrates the enamel technique in both its good and bad aspects, and it was through these, rather than the Swiss, hat the new site penetrated to England. Abraham and Bernard was Linge (who flourished about 1620-49 and painted many windows in Oxford and elsewhere) were the chief of these immigrants, but they were ably imitated by native artists such as Henry Gyles of York (1645-1700), the Price and the Peckitt families of the same city, and by artists like Francis Eginton (1737-1805) and James Pearson (d 1805), who carried the art right on to the threshold of the 10th century. At their best, the achievements of the glass of the 19th century At their best, the achievements of the glass painters in this genre have a miniature delicacy and a perfection of means beyond reproach But it must be realized that we have entered on a new art, with its own aesthetic, and we must beware of any in England (and elsewhere in Europe) it was the glass painters who were guilty of confusion Social custom never called upon them for a domestic art comparable with Swiss glass painting, but nevertheless they attempted to apply the methods of the domestic glass painters (but without their technical skill) to the quite different needs of ec-

ENGLISH STAINED GLASS

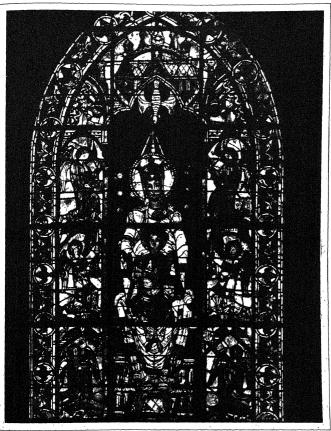

"The Patizeth Jards" 2014 sentury whickow in the south transpot of Centerbury Cathedral. As in much of the mediescry class re Englisher, the have dish is out in plick glass, while the rest of the design is a harmony of blues, pale green, whith, brown set yellow, arrange in thirty broad masser.

clesiastical buildings. The result was generally ludicious, and always inappropriate The crowning example of this misalliance of two in-consistent arts is to be found in the window designed by Sir Joshua Reynolds for New College chapel, Oxford, which was actually carried

out by a china painter.

The art of glass painting in England during the 17th and 18th centures does not offer sufficient material for any comparative criticism or positive judgment. We see nothing but scattered individuals, each expressing his own wayward fancy, displaying some ingenuity, supply-ing some passing need, but actueving nothing of significance Eighteenth and Nineteenth Centuries.—The Gothic revival

that came as an offspring of the Romantic movement of the late 18th and early 19th centuries was not without its effect on the art of stained glass. The styles and methods of the early Gothic period were reconstructed, but devoid c'all inner reason or inspiring sentiment thus reduced to sterile formulas was easily commercialized, and factories thus reduced to sterile formulas was easily commenculized, and factories for the manufacture of windows, any size, may subject and colours to tasks, sprang up all over Europe, but especial in machine the following the state of the colours of the and, indeed, eventually of Europe We cannot enter here into the general character of Morris's achievements, but the basic fact upon which all his ideals rested was an intense aesthetic appreciation of mediaeval art. As much, perhaps, can be said of the initiators of the Gothic revival, though we may suspect that as an aspect of romanticism Cottine revivat, trough we may suspect that as an aspect or formaticism their enthusiasm spraing from a sense of the temoleness, the strangeness, and the mysterious gloom of this earlier art rather than from any real understanding of its rational basis or religious significance. But Morris had a more logical appreciation of the Gothle, and his attitude Morris had a more logical appreciation of the Gothic, and his attitude was as free from instanctity, as it was devoid of any desire to instate. He realized that without the spirit, the form could not cast, and his real greatness and overwhelming importance in the listory of modern could be an experiment of the listory of modern cycles a style and invent a technique appropriate to the expressions of his age. Burne-Jones designed his first cattorious for staned glass as early as 1857, and the St. Fideswide window in Christ church, Messer Powell of the St. Fideswide window in Christ church, Messer St. Powell of the Whitefrans Glasshouse, but from 1650 insurance Jones worked exclusively for Morris Staned glass was included in the first chultion of the work of Morris, Marshall, Faulkner company in 1650. But the work of this period is weak in design and uncertain function of the leads in the design, and the enamels are either poor in technique. No attempt had been made to work out the proper junction of the lands in the design, and the enamels are either poor in quality or badly fired. But even so, there was a certain freshness of attitude and for statined glass increased, so more thought was given to these matters and the improvement was rapid. In Moiris's fully develoced style, as in the catabedral at Brimingham, there is little to complain of an the technique of his glass. Time has yet to show whether the materials will weather so well as the 15th-century mathe matter with weather so was at the intercept, the did not make his own glass, but obtained the best he could find in the market. In other technical matters Morris need not fear comparison with the could be the could find in the market. with any age. His selection and disposition of colours is adminished with any age. His selection and disposition of colours is adminished and he was not draifed of using new colours to achieve effects unknown to previous ages. In the use of leads to emphasize design he is masterly, and we must go back to the 13th century for an adequate comparison. The best examples of windows by Morris and Burne-Jones are to be found in Chief church, Oxford (the St. Cedina and St. Catherine windows of the Church, Church (the St. Cedina and St. Catherine windows of the Church, Church (the St. Cedina and St. Catherine windows of the Church, Church (the St. Cedina and St. Catherine windows of the Church, Church (1832), the well-known windows and own of the Church (1832), the well-known windows and (perhaps the most important in London) the windows at Holy Trinity. Some after With its repetited to be one of the finest examples of this continuation of the Church (1832), the confined in the main to Biblica subjects, Burne-Jones and Morris and confined in the main to Biblica subjects, Burne-Jones and Morris and with any age. His selection and disposition of colours is admirable, riage at Cana. In addition to all the work designed for churches, and confined in the main to Biblical subjects, Burne-Jones and Morris made a good deal of stained glass for domestic or secular purposes. In their choice of subjects for this profane glass, they perhaps unduly confined themselves to the romantic and literary predilections of their circle; themselves to the romantic and interary predilections of their circle; but here again we cannot criticize their stained glass without entering into a discussion of their whole point of view. It is perhaps sufficient to say that it lacked the immediacy and the reality which we are entitled to expect from any contemporary expression of ideals. The principles which William Morris established and followed give

The principles which William Morris established and followed give us an adequate criterion for the critism of modern stained glass. It is sail to contess how luttle those principles have been followed in the contest of the contest of the day. And it all directions patients and the significant artist of the day. And it all directions there is a relapse mion a service and lifetes mulation of mediaeval man-esting, due to a natural disregard for those self-scarticing ordinances which Morris observed. It seems that only the complete filling of every window in every old church will ever terminate this atrocous vandalism. There might be some satisfaction in the prospect if it were certain that that would put a stop to what is known in the trade as

"penod work", but these pastiches of the ait of other epochs find their way into practically every new church that is built, and the only hop, of any reform would seem to he in the final trumph of those principles of any reform would seem to he in the mail ritimph of those principles for which Wilham Morris stood. For these punciples are not altogether dead, they have merely migrated, and on the continent, especially in Germany, there is a school of glass painting which is not only modern in intention, but is inspired by all that is vital and significant in modern art

modern art Like the stained glass of William Moris, this modern continental stained glass is both religious and secular. The work of Jan Thoin-Prikker and of Karl Schmidt-Rottluff has given to the symbols and images of Christianity a new intensity and realism for which there is no parallel this side of the Renaissance, and the abstract designs in no parallel this side of the Renassance, and the abstact designs in which these glass painteis have experimented seem to open up infinite possibilities for this art of pure coloui and light. These attists work, under the direction of Gottfreid Henersderif for the Beitin firm of Puhl and Wagner. In France, interesting experimental works being done, for example, by MM Maumejean of Pars and Hendaye Stained glass, which dominates all other arts in this matter of colour, would seem to be peculiarly fitted for those experiments in abstract design and harmony which have been distinctive of a certain phase of modern at The difficulty in all contemporary glass-painting of a nonecclesiastical kind, is not so much to extend the possibilities of the art in the duection of design and actuality, but rather to find a function for the art itself. For that we must look, with whatever faith we can summon, to those manifestations of civic and commercial enterprise for which our gas is distinguished. At Hagen, in Germany, the railway attation has age is distinguished. At Hagen, in Germany, the railway attation has newspaper, Littisansignati, have windows with appropriate design by Henn Navarie executed in leaded glass by Geatan Jeanni But these are soluted instances of what seems to be the only chance of a manifestal resource of the art are greater than they have ever been. All that is lacking is the clearing, and the control of th those manifestations of civic and commercial enterprise for which our consciousness of the unique and unrivalled beauties of the art as it has existed in the past

STAINES, an urban district in the Spelthorne parliamentary division of Middlesex, England, 17 mi, S.W. of London by road Pop. (1951) 39,983 Area 129 sq mi. A Roman village was situated at the Thames on the main road from London, and the crossing was one of the earliest bridged. The existing bridge, designed by George Rennie, was opened in 1832. Stames (Stanes). first recorded in 969, also appears in Domesday. The London Mark stone was placed there in 1285 at the western limit of the City of London's jurisdiction over the Thames. An annual fair was granted in 1228 The urban district also includes Ashford, Laleham and Stanwell Though chiefly residential, Staines manufactures linoleum among other things and engineering is carried on. STAINLESS STEEL. Stainless steel basically is an alloy

of chromium and iron containing more than 10% chromium. When chromium is added to iron in such quantities, it imparts throughout the entire body of the metal remarkable resistance to corrosion and heat. Other elements may be added to the ironchromium combination to obtain steels with special characteristics. The most important of these is nickel, which is used to produce 18-8 (that is, 18% chromium, 8% nickel, balance iron). Other useful additions are columbium, manganese, molybdenum, phosphorus, selenium, silicon, sulphur, titanium and zirconium, all of which result in modifications for special service or fabrication. As is true of many scientific discoveries no single nation STAIR 29

can claim full credit for the development of stainless steel Between 1903 and 1912 Harry Brealey of England, F M Becket of the United States and Benno Strauss and Edward Maurer of Germany shared in its initial development

Selected scrap which contains only those elements desired in the finished product usually make up the bulk of the furnace charge used for producing stainless steel. If alloy scrap is not available, clean open-hearth scrap may be used, but more alloy is required to meet specifications Pig iron containing 4% carbon. anthracite, or other carbonaceous material may be employed when a high-carbon melt is desired Lime, silica, crushed coke, aluminum, silicon, fluorspar and iron one are materials used for slag constituents and for controlling the composition of the metal bath Because of the high temperatures and precise chemical control requited, all stainless steel is produced in the electric furnace Oxidizing and reducing slags may be used successively in the same heat, depending on the composition of the charge and the analysis of the product. Sulphur is removed from the metal with a reducing slag containing more than 2% calcium carbide, and silicon, phosphorus, manganese, chromium and carbon, with an oxidizing slag However, carbon presents a problem in the presence of chromium, because of the chemical affinity chromium has for carbon. Carbon may be absorbed by the metal at the same time chromium is being oxidized and going into the slag. To oxidize carbon in a charge containing a high percentage of stainless steel scrap requires an excess of oxygen and extremely high temperatures (more than 3,200° F ) Oxygen supplied through a lance into the molten bath is used to a large extent to replace iron ore as a source of this element Considerable chromium is oxidized percentage of chromium oxide. Chromium oxide may be reduced and returned to the metal by the addition of lime and crushed formeilican

The stanless sieels may be grouped according to chemical composition and response to heat treatment as follows: (1) ferritus steels, nonhardenable steels containing 15% to 30% chromium and with low carbon contents (from 0.6% to 0.00%), (2) martenistic steels, hardenable (by quenching) steels containing 10% to 18% chromium with varying calibon contents (5.08% to 1.10%), and (3) austenitic steel containing 15% to 50% chromium and 6% to 25% incide, which is hardenable without quench-incident contents of 1.00% to 2.00% chromium and 6% to 2.00% incident which is hardenable without quench-incidents.

ng.

Ferritic Stainless Steels are better than the martensitic type
and as sood as the austentic type in resistance to cortosion. Howeven, because of their lower ductility they are not used to replace
the austentitic type. Ferritic steels are magnetic and can be hotand cold-worked but sually undergo excessive grain growth during prolonged exposure at elevated temperatures. They have
lower high-temperature strength than the other two types and
may develop brittleness after electricart, resistance or gas welding Machinability is good and can be improved by adding sulphur
or selenium. There is no tendency toward intergranular cortoson.

The production in the United States of ferritic stainless American Iron and Steel Institute (AISI) type 430, widely used for automotive and architectural trim, was approximately a third of the total ingot stainless production in the 1950s.

Martensitic Stainless Steels are magnetic; they can be coldworked without difficulty, especially when the carbon content is low; show satisfactory resistance upon exposure to weather, water and some chemicals; can be machined satisfactorily; have toughness; and are easily forged or otherwise hot-worked. The corrosion resistance is usually increased by hardening, which is accomplished by quenching. Welds made by the electric-are, resistance or gas methods contain some martensite after cooling in air A.I.S.I. type 40 is the most widely used of the martensitig grades. In sheet or strip form, this grade is used extensively in the oil industry for bubble trays, bubble caoss and liners.

Austenitic Stainless Steels are not magnetic unless severely cold-worked. They can be hot-worked, and cold-worked if proper allowance is made for their rapid work hardening. Except for surface hardening, their alloys cannot be hardened by heat treatment. They are extremely shock-resistant and difficult to machine unless

they contain sulphur or selenium. These steels can be welded with difficulty, and, if the welding operation is controlled properly, the resistance to cornoson is not impaired. These steels have the best high-temperature strength and resistance to scaling of the stanless steels. However, they are subject to intergranular corrosion at temperatures between 80°c and 1,60°°F, unless the stucture is stabilized to prevent the presence of carbides at or near grain boundains which are vulnerable to corrosion. Stabilization may be done by the addition of ittainum (4 to 6 times the carbon content) or columbium (8 to 10 times the carbon content), which combine with carbon and prevent the formation of chromium carbides. The corrosion resistance of the austentic stainless steels is usually better than that of the other two groups.

A I SI type 304, a companion grade to types 301 and 302 with somewhat lower carbon (0.08% maximum), is the most widely used of austentic grades. It is well suited to withstand severe forms of corroson encountered in the paper and chemical industries. The austentite grades most resistant to oxidation are types 309 and 310, which are high an incleal and chromium. These steps resist seasts scaling up to 3,100° F, and consequently are used for furnace parts and heat exchangers.

The heat treatment of stainless steels may be carried out with any conventional type of electric, gas-fired, oil-fired, salt-bath or induction furnace. Although all stainless steels are highly resistant to oxidation, they may be expected to scale slightly at high heat-treating temperatures. The scale formed on the stainless steels is tenacious and relatively imporvious and, consequently, is more difficult to remove than scale on ordinary carbon steel. Two basic methods are used mechanical, such as sandblasting and tumbling; and chemical, such as pickling in and solutions.

An important development in the stanless steel industry was the increased use of austentic stanless steels containing manganese instead of inckel as a major alloying element. These were substituted for A.I.S.I. type 907 (18% Cr, 5% Ni), because of the current shortage of nickel. Manganese, like nickel, has the property of producing an austenitic structure in steel, although it takes twice as much to do it. Steel containing 15% Cr minimum, 16 5% Mn, 0 10% carbon maximum, and 1% Ni as a substitute for type 307 stanless is being used

for type 30r stamless is being used

STAIR, JAMES DALRYMPLE, 184 Viscourt (16191693), Scotilas haveyr and statesman, was born in May 16191693), Scotilas haveyr and statesman,

1695), Scottish lawyer and statesman, was born in May 1619, at Drummurchie in Ayrshire. After seven years as regent of the University of Glasgow he resigned, going to Edinburgh, where he was admitted to the bar on Feb. 17, 1648. In 1649 he was appointed secretary to the unsuccessful commission sent to The Hague to treat with Charles II by the parliament of Scotland, and was sent in the following year to Breda, where the failure of Montrose's expedition forced Charles to change his attitude and to return to Scotland as the covenanted king. Stair met him on his landing in Aberdeenshire He refused in 1654 to take the oath of allegiance to the Commonwealth. Three years later (1657), Stair was appointed a commissioner of justice in Scotland, on the recommendation of Monk. After the Restoration he was received with favour by Charles, knighted, and made a judge in the court of session. He refused to take the declaration that the National Covenant and the Solemn League and Covenant were unlawful oaths, and, forestalling deposition, he resigned. The king, however, summoned him to London and allowed him to take the declaration under an implied reservation. In 1669 a family calamity, the exact facts of which will probably never be ascertained, overtook him. His daughter Janet, who had been betrothed to Lord Rutherford, was married to Dunbar of Baldoon, and some tragic incident occurred on the wedding night, from the effects of which she never recovered.

In 1670 Stair served as one of the Scottish commissioners who went to London to treat of the Union In Jan 1671 he was appointed president of the court of session. In 1672, and again in 1673, he was returned to parliament for Wigtownshire When the Test Act was enforced Stair, dreading a fate similar to that of Argyll (q.v), went to London to seek a personal interview with the king, but the duke of York intercepted his access to the toyal ear, and when he returned to Scotland he found a new commission of judges issued, from which his name was omitted He retired to his wife's estate in Galloway, and occupied himself with preparing for the piess his great work, The Institutions of the Law of Scotland, which he published in the autumn of 1681. with a dedication to the king He repaired to Holland in Oct. 1684, and took up his residence, along with his wife and some of his younger children, at Leiden, where he published the Decisions of the Court of Session between 1666 and 1671 and a small treatise entitled Physiologia nova experimentalis

In his absence a prosecution for treason was raised against him and others of the existe by Sir G Mackenae, the lord advocate, but it was dropped, owing to the appointment of his son, the master of Stair, who had made his peace with James II, as lord advocate in place of Mackenae. Stair returned from Holand in the suite of William of Orange In 1680 he was again placed at the head of the court of session. He was attacked by an anonymous pamphleteer, perhaps Montgomery or Ferguson the Plotter, in a pamphlet entitled The Late Proceedings of the Parliament of Scalland Stated and Vinducated. He defended

himself by publishing an Apology.

Shortly aften its issue he was created Viscount Stair (1599). The massacre of the Macdonalds of Glenco (Feb 13, 1699), for which his son, the master of Stair, was largely responsible, naturally reflected on him On Nov 29, 1699 Stair died in Edmburgh Stair's great legal work, The Institutions of the Law of Scotland deduced from its Origandia, and collated with the Civil, Connon and Faulist Laws and with the Custows of Neighbouring Nations is important to the Control of the Control o

STAIR, a series of steps arranged one above the other, occasionally varied by platforms known as "landings". The total height of a starr is the "rise," the total horizontal distance between the top and bottom steps is the "run". A series of steps without a landing is called a "light." The horizontal surface of a step is called its tread, and the vertical front its riser. The projection of the tread beyond the face of the riser is termed a nosins.

Long use has demonstrated that certain proportions of riser and tread are safe and easy. For interior stairs twice the height of the riser, plus the length of the tread, should be 23, all dimensions being ninches A variant is that the sum of rise and tread should be between 17 and 17½ in; a third rule specifies that the product of rise and tread, in inches, should be not less than 70 nor more than 75. In general, English usage advocates a slightly lower rise for a given tread than American usage, while in Europe the rise is frequently greater. For exterior stairs, the general usage is to keep the rise place of 10 and the tread above 12.

It is uncertain what is the oldest stair in existence. On the sacred road up the mountain of Tai Shan, in Shantung, China, there are many great flights of ancient granite steps. In Egypt stairs in pylons exist which date from the second millennium BLC. Assyria has left massive stairs on the siggurats ( $q \circ v$ ), which date from the 9th and 8th centuries, B c; and the palace terrace at Persepolis has a double flight of steps, of great beauty, which shows the skill of the Persians in the 6th century B.C.

ruther west, stairs play an important part in the Cretan palistr Walter Scott took the plot of his Bride of Lammermoor from this incident, but he disclaimed any intention of making Sir William Ashton a portrait of Lord Stair.

aces, as in the palaces at Knossos and Phaistos (both c 1500 BC). In Helienic Greece the monumental stair was of less importance. due to the Greek love of informal and picturesque approaches Thus in Athens the propylaca of the Acropolis was probably entered by a winding path and the present great flight of stairs, dating from the Roman period, is not part of the original design. In the post Alexandrian period there developed a new love of monumental grandeur, largely Asiatic in origin, which produced such magnificent stairs as those of the altar of Zeus at Pergamon (180 BC) A similar monumental sense distinguished Roman stairs Those of the propylaea at Baalbek (time of Hadrian), over 100 ft wide, are typical, and again and again stails are made essential parts of great architectural conceptions, as in the temple of the Sun on the Quirmal hill at Rome, built by Aurelian (AD 273), some of the steps of which were taken, in 1348, to build the famous stairs of the Aracoeli on the Capitoline hill at Rome

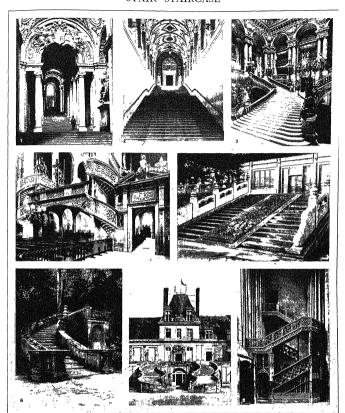

Although during the middle ages stairs were used more for utilitarian than aesthetic purposes, where they were necessary they received adequate treatment, usually more direct and informal and more picturesque than those of the Roman tradition. Thus at Le Puy en Vélay, in France, the 11th century cathedral, which was built on a hillitop, is approached by a magnificent stair that provides a superb foreground to the polychrome façade. The steps that mount up to and past the apse of the 14th century cathedral at Erfort, in Germany, show the direct and beautiful relationships between the building itself and the stairs which is characteristic

of the best Gothic usage

The Renaissance produced a recrudescence of the tradition of Roman formality in stair design Particularly magnificent are the stairs of the Baroque period, such as the so-called Spanish stairs at Rome in the Piazza di Spagna (1723-26), by F de Sanctis, those of the Campidoglio, at Rome (begun 1547), by Michelangelo and the infinitely varied terrace stairs of the Italian villas. The inspiration of these Italian Baroque stairs was felt throughout Europe and is largely the foundation of stair design in modern city and garden planning. Thus the enormous stairs of the gardens of Versailles (1667-88), by A Le Nôtre, owe much to the Italian precedent, and were themselves imitated widely all over Europe. Among modern stairs may be noted the extremely lavish stairs of the monument to Victor Emmanuel II, in Rome (begun 1885), by Giuseppe Sacconi, with the altar of the Patria, the broad flights leading up to the library of Columbia university, New York (1896), by McKim, Mead and White; Waterloo steps in London (1831-34), by Benjamin Wyatt and those of the Lincoln memorial at Washington, D.C. (1924), by Henry Bacon

In the Orient, the stairs leading down to the river at Benares. in India, of various dates, combine monumentality and picturesqueness; a sımılar skill is shown in the design of large numbers of temple and palace steps throughout the peninsula Further east the rums of Angkor use wide flights of steps with magnificent effect in connecting the various levels of the terraced group. The Chinese have always been superb stair designers and builders. and there is hardly a temple or large house or palace which does not owe some of its effect to its stairs, either monumental and formal, like those of the Forbidden City or the Temple of Heaven. both in Peking, or winding and informal, as in Chinese garden design Many of the temple stairs have, in the centre, an inclined plane running the entire height of the rise, richly carved with the symbolic dragon-the so-called spirit stairs by which the beneficent powers are supposed to enter In Japan the tradition is much more informal, but the hilly nature of the country makes stairs an important feature of almost every temple layout. (T. F H)

STAIRCASE, a term for stairs accompanied by walls The carriest staircases seem to have been built with walls on both sides, as in Egyptian pylons Contemporary models of houses, dating back to the Middle Kingdom, show a staircase leading up the side of a court to a roof terrace, with continuous wall below. The origin of such stairs may have been earlier structures in word, or even ladders cut out of logs. Egyptians may have used the self-supporting staircase in which each step is supported at from the three of the such content of the such co

- Staircase by John Russell Pope in the Sloane house in New York, a characteristic modern interpretation of late Georgian delicacy and detail
- 2 The starcese of the third quarter of the 18th century, in the Moffatt-Yard-Ladd house in Portsmouth, N H., characterized by the panels, bracketed ends and lavishly turned batusters, so typical of the developed American colonial
- 3. The famous stairs of the Petit Trianon at Versallies, though built by Gabriel in 1766 under Louis XV, show a simple delicacy and a use of straight lines characteristic of the style known as Louis XVI.
- 4. Much more typical of Louis XV work is the lavish and monumental
- stairs of the Hôtel de Ville at Nanoy, France, designed by E Here, with Iron work by Lamour
- 5 Modern freedom in design, the effort to combine many materials and to contrast straight and curved lines, characterize a stair designed by Patou in a Paris shop (La petite Jeannette)
- 6 The circular, concrete staircase in the Martel house in Paris, designed by R Mallet-Stevens, an austere simplification of the more extreme types of modernism
- In his Parls house, the same architect, Mallet-Stevens, combines concrete stairs with a railing of aluminium whose narrow aluminium supports, set at varying angles, catch varying reflections

Greece and Rome.—In classical Greece, interior staricases were common but unimportant, they were placed in out of the way corners, and often built of wood In Rome, a new treatments for staricases became necessary Many of the apartment houses indicated on the marble plan of Rome (c. AD 205), now in the Pakazo dei Conservatori at Rome, seem to have had stair towers built in the centic of a courtyard The Colosseum (ap.) at Rome (completed AD 80) has elaborate and practical entrance and exit stars, by which the crowds could be readily handled. These, in general, are supported by sloping vaults and roofed by others Similar stanicases were common in the heaties.

Byzantine and Romanesque—Merely inclined planes lead up within enormous buttersses at the ends of the nathex of S Sophia (537) at Constantinople, so giving access to the galleries. In S George at Solonca (late 5th century), a spiral starcase surrounds an open well In the early Romanesque there is a growing use of the spiral starcase. To this development the great thickness of Romanesque walls and butteresses was particulally congenial, as it allowed the staircases to be built in solid masonry. Not only was the open circular well used, but the solid newel, in which each step had cut upon it a cylindrical form to act as part of the newel This type of spiral staircase is still in use

Gothic .- The Gothic spiral staircase was cut with the utmost cleverness. We have the radial stone cut in two levels, so that the ascent was twice as fast as by the ordinary method, thus allowing the radius to be remarkably decreased Such circular staircases as lead up in the traceried turrets of the spire of Strasbourg cathedral in Alsace (1435) are miracles of daring design and delicate execution. The late Gothic period also produced a great number of beautiful interior staircases, like the "Stair of the Library" in Rouen cathedral (1477-79), which show that the possibilities of the staircase with straight runs were at last being realized. Of rich interior spiral staircases, the early 16th century staircase leading to the organ in S. Maclou, in Rouen, and the contemporary staircase to the jube (qv), or rood loft, of S Etienne du Mont in Paris (in which a certain amount of Renaissance feeling is piesent) are noteworthy In the larger houses the lack of communicating passages led to many staircases. Thus in the house of Jacques Coeur at Bourges (c 1450), there are eight separate spiral staircases, whose exterior treatment, in rich, tracened towers, furnishes a great deal of the picturesqueness and varied beauty of such a building.

Renaissance.--During the Renaissance, despite such tours de force as Vignola's spiral stair in the palace at Caprarola (c. 1550), the general practice was to have important staircases run up in a straight flight, sometimes varied by landings, and sometimes with changes in direction between walls often crowned with a slanting vault. The most perfect developments of this type were made chiefly during the Baroque period The magnificence of the huge interior flights of the Genoese palaces (e g., the "University," 1623, by Bianco) is famous The Scala Regia is particularly remarkable in the artificial exaggeration of its perspective, through the gradual diminution of width and height as the steps ascend. In France the spiral staircase added by Francis I. to the château at Bloss (1515-24) and the double circular staircase of the château of Chambord (begun 1519) are remarkable. The early Renaissance, however, produced its most remarkable results in the richly ornamented wooden staircases of Tudor and Jacobean houses. The usual arrangement was to have the staircase divided into comparatively short flights, at right angles to each other, around a central open well; the heavy newels at the corners were finished with urn-like finials at the top and carved drops at the bottom, the railing consisted of a large rail supported either by miniature arcades or square balusters, whose mouldings were often sloped to follow the stairs, and the whole was covered with intricate surface ornament of strap work. The staircase at Hatfield house (1611) is typical. The early Renaissance staircases of Spanish palaces are in most cases placed in one corner of the courtyard and run up between walls to a landing with a return flight that opens out onto the upper floor gallery. The walls, and sometimes even the treads and rises, are often cased in brilliant faience tiles. Even in staircases of more Italian type, with balusters, the rich-21-L

ness of wall surface remains, as in the staircase of the hospital of Spanish Renarsance monumental stair design is reached in the "Escalea Dorada" at Burgos cathedral (1519), by D. de Siloe, with its evolusie metal railure.

The developed classicism combined with the Baroque of the later 16th century to give a new trend to staircase design throughout Europe Thus in France a gorgeous series of staircases was produced, of which the "Escalier des Princes" of Versailles is typical. The reaction to the lightness and gasety of the Louis XV period (see Louis Stylks) led to the development of many gracious and inviting house staircases of the type known as self-supporting, full of sweeping curves and with railings frequently of metal In the Louis XVI period the new, popular classicism restrained the exuberance of the earlier staircases but retained their graciousness and lightness, of these, one of the loveliest is that of the Petit Trianon at Versailles (1766), by Gabriel, with a beautiful iron railing Meanwhile, the classic trend had expressed itself in England by the substitution of open string for closed string stairs, that is with the balusters coming down to the top of each tread, rather than being supported on a slanting member, or string, which received the ends of the treads This at once made for a more interesting treatment at the ends of the steps, and led, eventually, to the development of the bracketed step end, in which scrolls and leafage of great richness were carved under the end of each riser. Moreover, the fact that English stairs were largely of wood inspired the design of turned balusters and newels of great variety During the last half of the 18th century, a growing trend toward lightness and delicacy of design led to the substitution of plain. tapered shafts in place of elaborate balusters, and the use of stairs rising in continuing curves instead of straight flights and landings. The same development took place during the 18th century in the colonial work of North America Thus certain of the earliest houses, like the Capen house at Topsfield. Mass (1683). have closed strings and heavy newels of Jacobean type, while the open string staircase, whose steps have papelled and scrolled ends. and whose twisted balusters are as rich as any contemporary work in England. The curved staircase of the Valentine museum at Richmond, Va (1812), is typical of the later delicacy

Modern.—During the middle and the third quarter of the 19th century, starcase design reached its lowest ebb, not only in England and France, but throughout Europe, except in the case of those monumental and official buildings on the Continent the design never fell a victim to the current taste. Closed strings again became the fashion and balusters and newest of garganing proportions and bulbous and meaningless elaboration. Yet one of the most gorgeous and effective staircass in the world deter from this period, that of the Paris Opéra (1861-74), by Charles Garnier.

Two elements have vastly affected modern staircase design, steel and reinforced concrete The use of steel has led to simple plans of straight runs and railings delicate and straightforward in design, with newels usually accented, as in the Jacobean wooden stairs. Reinforced concrete, on the other hand, is a material so facible that the most during curves and fantastic aweeps become structurally sound. Probably the most brilliant example of this modern type of staircase design is in the new portion of the Galeries Lafavyette at Paris (1926), by F. Chanat, a conception of diazying lightness, with modernist iron raillines.

### STRUCTURAL DESIGN

Stone and Marble Staircases.—Modern stone and marble staircases are of two main types. In the first the actual exposed treads and rises form, themselves, the structural elements. In the other type the treads and rises are supported upon a separate structural base which may consist of a masonny vault, a steel framework or a reinforced concrete slab. In the first class, in which the steps themselves are structural, the staircase is usually built into a wall at one side. Each step rests for a small distance upon the step below and is built into the wall for a distance sufficient to make the weight of the wall above prevent it from turning. The undersides of the steps, where exposed, are frequently cut to form an inclined surface, following the slope of the stairs, and may be decorated with panelling or carved or other ornament. This type of stair can be used both for straight and curved runs, and is particularly applicable to monumental entrance halls, where the stair, in a triple run with two landings, or in a continuous, curved sweep, fills a recess opposite the door in such straincases the railing is usually of metal with the uprights securely dowelled into the ends of the steps Stairs somewhat similar can be built with the ends of the steps stairs somewhat similar can be built with the ends of the steps study into the walls on both sides, where a monumental jun rases believen two walls

Wooden Staircases.—These can be divided into two classes, closed and open string stairs. In both the essential support is given by rough timbers called carriages, which follow the slope of the stairs and are cut roughly to the shape of the under side of the steps. In the case of closed string starrcases both sides of the staircase are finished by a sloping, straight-sided plank, approximately an inch and a half thick, on the inner faces of which grooves are cut, whose upper and outer faces exactly fit the top and side of the tread and riser, the under and inner sides are, however, sloped, so that wedges may be driven in to force the tread and riser boards into position and hold them with perfect rigidity. Similar wedges are driven in between the rough carriages and the under sides of treads and risers To give additional strength, the treads and risers are, themselves, rebated together, so that a small, projecting strip of the tread fits into a groove in the bottom of the riser, and a similar strip on the top of the riser fits into a groove on the bottom of the tread. The projecting portion of the tread is moulded and an additional small cover mould placed below to cover the joint

In the open string staircase the strings at the end are cut to the shape of the steps, and the vertical cuts are usually mitred at 45°, so that the ends of the tiered stowers are the string at the ends of the treads dove-tailed sockets are left to receive the dove-tailed ends of the balusters; a moulding, exactly similar to the nosing, as then applied across the end of the step, and covers the bottom of the balusters. At times, bracketed and carved pieces are mitred at the ends of the risers and applied over the face of the string. It is this type of staircase that was the rule during the Georgian period in England and mit the developed American colonial and early republic work. Where an open string stair is built against a wall, it is usually shished at the wall end by a closed or housed string, similar to that described, forming a base-board for the wall.

The structural strength for a wooden staircase is usually furnished by framing a heavy member, called a header, at the top and bottom of every run, to these headers the rough carriages are spiked, and the newels, if they exist, firmly fastened. The newels themselves are designed to receive the finished stair strings, and also the finished string member that is occasionally used at the edges of a floor in the stair-well opening. In staircases similar to those of the early 19th century in England and America, in which newels did not exist, except at the bottom, and in which stair rails and balusters were of the most extreme attenuation, and the whole frequently laid out with complex curves, strength was achieved by the most exquisite workmanship, whereby the careful framing of every part made the finished staircase an independently rigid structure. Frequently the curved plan itself furnished a certain amount of lateral rigidity. In modern staircases of this type additional strength is obtained by inserting iron or steel bands into the hand-rail; occasional balusters may be of steel, well fastened to the string.

Stecl Staircases.—These have become almost universal in modern freproof buildings of all types, except where unusual monumental effect is desired, and the design of steel staircases is largely standardized. They consist of a steel string on each se, which takes the form of a plate or channel of sufficient rigidity to carry the weight.

Iron spiral staircases are usually formed of cast iron members, each of which forms a tread and riser, and has at its inner end, a collar arranged to slip over a vertical pipe or cylindrical bar forming the central newel. Such spiral staircases are rigid independ-

ently of any wall, and are frequently used in open spaces, such as those existing in power houses, gymnasums and the like Renforced concrete, sometimes finished as artificial stone, is used for stairs and permits of infinite variety of form

Moving Staircases .- In many places where continuous transit between floors is necessary, as in large shops, underground railway stations and the like, moving stairs, sometimes known as escalators, are much used These are of two types. In one, an endless belt carries on its surface links or blocks of sufficient roughness to act as treads. This endless band, at top and bottom, rotates around wheels or pulleys, motor-driven At the bend the band disappears through the floor into a slot armed with steel aims, so designed as to occur one in each groove between the raised portions of the treads Another continuous band on each side, geared to the same speed, serves as a hand-rail. The other type has a similar mechanical basis, but the belt, instead of carrying directly upon its upper surface blocks to form the treads, is designed to motivate actual continuous horizontal treads with risers radially shaped, so that at top and bottom the treads slide up on the risers into a continuous moving plane Moving handrails are furnished as in the other type, and in addition, a moving band angularly across the top and bottom, to remove automatically any dropped objects. Moving stairs of the second type are always entered and left at the side, those of the other type directly at top and bottom

Legal Regulation .- As stairs form one of the most necessary methods of exit from a building, their design has formed one of the most important portions of the building legislation of modern municipalities, especially in the case of public, commercial, industrial and educational buildings. Although there is much variation in the detailed requirements of different cities, the methods of regulation are almost the same and state. (1) where fireproof stairs are required, (2) the number of staircases, (3) size, (4) design. Thus, in addition to the universal requirements for structural solidity, the attempt is generally made to furnish at least two stair exits to any large, enclosed, upper floor area; and where fire risk and the danger of panic are unusually great, as in the case of theatres, to demand sufficient stairs to allow the building to be emptied in a very short time, without disorder. Widths of stairs are frequently determined in accordance with the number of people using them In New York, for instance, each staircase must be designed to contain all the people of the floor area it serves, on the basis of one person to each 21 in of width and each one and one half treads. Design is controlled by specifying the relationships of tread and riser, the distance apart and size of landings, whether or not curved stairs are allowed, etc , and often, because of the smoke danger, requiring exit stairs to be enclosed in a fireproof tower, with fireproof, self-closing doors at all entrances BERLIOGARTEW —A. Swan, The British Architect or the Bulder's Treasury of Statrases, Viollet-le-Duc, Dictionname Raisomé de Flarchitecture (1854-76); Letaroully, Edifices de Rome Moderne; F. E. Kadder, Bulding Construction and Superintendence (1911), C. A Martin, Détails of Bulding Construction (1905); Byne and

STALACTITES are pendent masses formed where water containing mineral solutions drops very slowly from an elevation. (Gr. σταλακτός, from σταλάσσειν, to dup ) They are seen, for example, beneath bridges, arches and old buildings where water percolating through the joints of the masonry has dissolved very small quantities of the lime present in the cement and mortar between the stones. On exposure to the air part of the water evaporates and the solution of calcium carbonate becomes supersaturated; a deposit of this substance ensues and as the drop continues to fall from the same spot a small column of white calcite very slowly grows downwards in a vertical direction from the roof In the same way stalactites of ice (icicles) are produced in frosty weather as the water dropping from eaves of buildings, elevations, branches of trees, etc., very gradually, freezes Other minerals often occur in stalactitic growths; thus we find in mines and in the cavities of mineral vems stalactites of limonite, opal, chalcedony and gibbsite. These are never of great size,

Stepley, Spanish Architecture of the 16th Century (1917), Spanish Interiors and Purniture (1921); P. G. Knoblauch, Good Practice of Construction (1923-6)

usually not more than 2 or 3in in length, and probably the method of origin is exactly the same as that of the larger and more common stalactites of ice and calcite.

The conditions essential to the perfect development of stalatics appear to be (1) a very low rickle of water from a fissure, (\*) segular evaporation, (a) absence of disturbance, such as currents of air Hence, ice stalacties form most readily on calm cold nights, and stalactites of ice or calcite are seen in greatest perfection in the interior of caves.

In limestone caves stalactites form in abundance as glimmering white columns covered with a thin film of water The great caves, such as those of Postumia (in Italy), Incolain (Australia), the Mammoth Cave (Kentucky), the Causses district in France, and the grottees of Belgium, are divided into chambers which are richly festooned with stalactites, and fancful mames are given to various groups according to their similarity to different objects, natural or artificial Ice caves of considerable size occur in the Airctic and Antartic regions, and are draped with fice stalactites often wonderfully like those of limestone caves

Where the water drops upon the floor of one of these caves evaporation still goes on and if the air be perfectly still the drop will always land on the same place and a pillar of deposit, called a stalagmite, will rise vertically, till in course of time it meets and joins with the stalactite above. As the stalactites thicken, they assume tapering forms with irregular surfaces. Large stalactites may be 3 or 4ft thick, but in that case they are usually due to coalescence of adjacent ones. Single stalactites 2ft in diameter are not rare. From data obtained by measurement of the rate of growth at the present day it has been estimated that as much as 200,000 years may have elapsed since certain thick stalactites began to grow Caves are of great antiquity but there is, of course, no certainty that the conditions have remained uniform. Sir Archibald Geikie records that stalactites 14in, in diameter had formed beneath a bridge in Edinburgh which was 100 years old, in caves, however, the rate of formation is rarely so great as this Inscriptions on stalactites in the Adelsberg cave after 30 years had been covered with a scarcely perceptible film of new deposit. In one of the Moravian caves a stalactite, about as thick as a goose quill, was broken across in 1880, and in 1891 it had grown 3 or 4cm, from careful observations it has been calculated that one of these stalactites, 7ft. long, may have been formed in 4,000 years The stalagmitic crust on the floor of caves is usually mixed with blocks which have fallen from the roof, sand, mud and gravel carried in by floods, and the bones of animals and men which have inhabited the cave if it had an accessible entrance.

Stalactites also occur in the internor of the lava caves found in Hawain, Samoe, etc Often the upper surface or a lava flow has cooled to form a crust, while the interior is still perfectly fluid, and it sometimes happens that the lupid bask has made its escape, leaving great cavities below the hollow roof of the lava. The interior of these caves is covered with a black shining film of glassy hasalt, and black stalactites of lava hang downwards. Their surface is sometimes changed to brown or red by the action of the acd vapours which filled the cave after the lava retired. These stalactities are tubular, with blumity rounded ends, and probably their mode of growth is somewhat analogous to that of fociets.

STALACTITE WORK, in architecture, one of the most general characteristic of all of the Mohammedna styles, consisting of a series of little niches, bracketed out one above the other, or of projecting prismatic forms in rows and tiers, connected at their upper ends by miniature arches. Its infinite varieties may be classified into three groups, the first consisting of those basically niche-shaped, in which the concave curve is the most important feature; he second group includes those in which the vertical edges between the niches are the most important of the control of the second group includes those in which the vertical edges between the niches are the most important of the control of the second group control of the control of the property of the second group consists of elaborately intersecting, miniature arches. The first two groups occur commonly in Syrian, Moorish and Turkish work and in their simpler forms, in Perisi; the last group is typically Persian and is found also in Mogul work in India.

Stalactites are of comparatively late development in Muslim art, the earliest buildings in Syna, Egypt and north Africa showing no traces of them. They seem to appear suddenly all over the Mushim world toward the beginning of the 12th century. Thus simple forms are found in the mosque at Ani in Armenia, built between 1072-1110, and they are common in Algiers and Sicily during the course of the century, as in the gate at Chella (1118-84), and in the building known as La Ziza at Palermo (1154) In Egypt the stalactite appears in panels flanking the main entrance of the El Akmar mosque at Cairo (1125-50). They reached their highest development in the 14th and 15th centuries, becoming the normal decoration for the heads of door niches and the bracketing under cornices and minaret galleries The richest examples of the prismatic type are to be found in Moorish work in Spain, especially in the intricate wood and plaster ornament of such palaces as the 14th and 15th century Alhambra in Gianada and the 14th century Alcazar at Seville In Turkey, a peculiar type of faceted crystal shape is found and the form became the most common capital decoration.

STALIN, JOSEPH VISSARIONOVICH (Dzzucasar-VILI) (1879–1933), leader of the Communit party of the Soviet Union, prime minister, generalissismo and dictator of the U S S R, was born on Dec 21, 1879, in the town of Gori, Georgia, Transcaucasia His father Vissarion Dzhugashvil, a poor shoemaker, died when Stalin was 11 years old His mother Ekaterina, the daughter of a serf, was an illustrate and deeply religious washerwoman After the death in infancy of three children, Stalin was her only son She brought him up with much tendemess and devotion and chose for him an ecclesiastical career in the Georgian Orthodox Church

The Young Revolutionary.—Georgian folklore, native tribal traditions, fresh memories of serfdom and Georgian patriotic (anti-Russan) sentiment were the strongest influences in Stalin's childhood He attended the parish school at Gori and, in the autumn of 1804, he matriculated at the theological seminary of Thiis (Tbilis) He was a very able pupil, a voracious reader and an ambitious debater. In 1896, while he was still at the seminary, he jonned the ranks of Messame Dassy (the Third Group), a Georgian patriotic and socialist organization; and he came under the influence of Marxism, which was rapidly spreading among the Russian and Georgian intelligential in 1896, when he was about to graduate, he was expelled from the seminary because of his "disloyal" vesses.

He plunged into revolutionary propaganda and agitation. At the turn of the century the revolutionary movement in Russia shed the ideas of agrarian socialism preached by the Narodniks and adopted the Marxist social-democratic program, advocated by G. V. Plekhanov and V I. Lenin in Iskra The young Stalin was a supporter of Iskra. In 1901 he was elected member of the clandestine Social Democratic committee of Tiflis Police persecution forced him to "go underground" Arrested in April 1902, he remained in prison until the end of 1903. But while in prison he was elected member of the Social Democratic committee guiding the movement in the whole of the Caucasus Deported to Siberia, he escaped from there and returned to Tiflis early in 1904, shortly after the Social Democratic party had split into bolsheviks and mensheviks. He joined the bolsheviks, who wielded little influence in Georgia. At this early stage he was already under the overwhelming influence of Lenin's writings, and in local clandestine sheets and periodicals he translated Lemn's ideas from the Russian into the Georgian.

In the revolution of 1905 Stalin played no conspicuous part, but was active in the background as an organizer of bolshevitk fighting squads and partitian groups. He had a hand in organning raids on treasury transports, the so-called "exes" (exprepriations) raids and using them to finance the party's revolutionary activity. Stalin first met Lenin at a party conference at Tampere (Tammersfors), Fin, in 1905. In 1906 and 1907 he participated in party congresses held in Stockholm and London; and in opposition to Lenin he advocated a policy of agrarian revolution identical with that later adopted by the bolshevits in 1917. After the defeat of the 1905 revolution he

STALIN 302

distinguished himself as the bolshevik leader of Baku Many times arrested and deported, he succeeded each time in escaping from the places of exile

In 1912 the bolsheviks finally broke with the mensheviks and constituted themselves into a separate party Lenin then co-opted Stahn as member of the new central committee Stahn (he began to use this pseudonym, the Man of Steel, early in 1913) was the first editor of Pranda, which began to appear on May 5, 1012 At the end of that year he attended important holshevik conferences in Cracow, Pol, and then went to Vienna, Aus, to write Marxism and the National Problem This important study was a theoretical argument in favour of the bolshevik program of "selfdetermination" of oppressed nations The work established his reputation as a foremost expert in this field, but he was looked upon as a man of action and an organizer, not a theoretician On his return to St. Petersburg he was again arrested, and deported to the Turukhan province in the polar circle He iemained in exile un-til the outbreak of the February (March, western calendar) revolution of 1917

Stalin's Role in 1917 .- Stalin's role in the events of 1917 was not prominent. This was the heyday of the brilliant revolutionary orators and agitators, and Stalin was not one of them. He was overshadowed not only by L D Trotsky, who was much more than an orator and agitator, but by G. E. Zinoviev, A. V Lunacharsky, Alexandia Kollontai and other less important bolshevik leaders After his return from Siberia in March, he became editor of Pravda and adopted a vaguely conciliatory attitude toward the provisional government of Prince Lvoy. Soon afterward the bolsheviks, prompted by Lenin, embarked upon a revolutionary course of action; but Stalin remained one of their chief organizers and Pravda's coeditor At the height of the antibolshevik campaign in July he organized Lenin's escape from Petrograd, and in the absence of Lenin, Trotsky, L B Kamenev and Zinoviev, he guided the 6th party congress immediately after the "July days." During the famous controversy which developed in September and October between Lenin, advocating an armed rising, and Zinoviev and Kameney, opposed to insurrectionary tactics. Stalin was among Lenin's adherents, although in Pravda he attempted to bridge the gulf between the two factions
Shevik insurrectionist "centre" which was to join the Military Revolutionary committee headed by Trotsky; but he played no part at all in the insurrection itself.

The People's Commissar .- After the bolshevik victory he was appointed commissar of nationalities, and he held this post for nearly five years. Under Lenin's guidance he set out to put into effect the party's program of "self-determination" for oppressed nationalities One of his first official acts was to proclaim on behalf of the new Russian government the independence of Finland. He participated closely in the working out of the first Soviet constitutions of 1918 and 1923. In 1919 he was, in addition, appointed commissar of the workers' and peasants' inspectorate, an important department whose function it was to supervise alt other branches of the Soviet administration.

His voice carried much weight in the inner bolshevik councils during the civil war (1917-21), although he continued to be overshadowed by Trotsky, the founder and inspirer of the Red army. As member of the council of defense, political commissar and inspector of fronts, Stalin was in charge of the defense of Tsaritsyn (Stalingrad) in the summer and autumn of 1918; he organized the defense of Petrograd against Gen. N. N. Yudenich's offensive m May 1919, and the battle of Orel in October of the same year, when the Red army halted Gen. A. I. Denikin's advance on Moscow and passed to the counteroffensive. He served as political commissar with S. M. Budenny's cavalry corps during the advance on Lwow (Lemberg) in 1920; and he was in charge of the preparations for the final campaign against Gen. P. N. Wrangel's army and of the dramatic battle of the Perekop isthmus, the last battle of the civil was. Some of these episodes, especially his role in the defense of Tsaritsyn and in the march to Poland, were the subjects of much controversy. During the civil war an intense rivalry developed between him and Trotsky, the commissar of war. Not without ground Trotsky charged Stalin with surreptitiously supporting the left-wing Communists who were opposed to the employment of old army officers in the Red army and to the army's centralized structure and discipline established by Trotsky Trotsky's influence remained paramount, but even in 1919 Stalin wielded enough power to bring about the dismissal of J Vatsetis. Trotsky's protégé, from the post of commander in chief and his replacement by S Kameney. After the civil war, in Feb 1021 Stalin initiated the bolshevik invasion of Georgia without the knowledge of Trotsky and the commander in chief

In April 1922, after the 11th party congress, the last congress attended by Lenin, Stalin was appointed secretary general of the party and relinquished his posts in the council of people's commissars This was a turning point in his career as secretary general he soon came to control the whole machinery of the party

and through it the government

The Succession to Lenin.-Lenin's illness in 1023 and his death (Jan 1924), coincided with a crisis of the revolutionary regime. The bolsheviks had from the beginning denied political freedom to the old ruling classes and their parties who opposed arms in hand the "proletarian dictatorship" But the bolsheviks had also pledged themselves to respect and secure "Soviet democracy." that is, freedom of political expression for the working classes and their parties. The proletarian dictatorship had been conceived as a system of representative government, but instead of a parliament, the councils of workers' and peasants' deputies were to form the representative organs. Toward the end of the Lenin era, however. the regime had already developed into a single-party system All nonbolshevik parties had been banned, and only within bolshevik ranks was some freedom of expression preserved. Inevitably the question arose whether the bolsheviks themselves could enjoy the freedom they denied to others The other critical development concerned the party's international orientation. The hope for an imminent spread of revolution abroad, which had inspired the bolsheviks, was decisively undermined in 1023 after the defeat of communism in Germany Bolshevik Russia was at last recognized by most bourgeois governments, but as a Communist state it stood alone. Bolshevism was withdrawing into its national shell and was ill at ease with the revolutionary internationalism of the Lenin era All these issues were brought to a head in the struggle over the succession to Lenin

In 1923 Stalin, Zinoviev and Kamenev formed a triumvirate with the purpose of debarring from power Trotsky, who was generally regarded as Lenin's successor In his last will Lenin advised his followers to "remove Stalin" from the general secretariat of the party on the ground that Stalin was rude and inclined to abuse power. But Stalin, supported by the other triumvirs, retained his office In a constant struggle against his opponents he abolished whatever

power. on the state approaches by the concentrations, relating any other powers and the party into a "monothic" body. In the autumn of 1944 he expounded the theory of "foculation in one country," proclaiming the eight marked a departure from Leiniust internationalism, although Statin and the state of the proclaiming of the state of the proclaiming the self-marked a departure from Leiniust internationalism, although Statin and the state of the present in the present proclaiming the proclaiming the proclaiming the proclaiming the proclaiming the proclaiming the present of the present proclaiming the proclaiming the present in the party's right-wing led by N. I. Budharm, A. I. Rykov and M. P. Tomsky. Zimovev and Kamenev, on the other hand, made common cause with Tokel's alphy with the present of the present present the kulast (well-to-de farmers), and demanded the restoration of "inner party democracy" At this stage Stain, androus to keep in line with the present of the present present the kulast with undertake a frive against the kulask and treated the demanded or rapid industrialization as unreal. But in 1928-20-9, after he had defor rapid industrialization as unreal But in 1928–29, after he had defeated and expelled from the party Trotsky, Zinoviev, Kamenev and their followers, Stalin turned against Bukharin, Rykov and Tomsky He then effected a most drastic change of policy and began to industrialize the U.S S.R. and to collectivize agriculture with a speed and traine in 0.5 s.k. and to conceiving agriculture with a speed and ruthlessness which horrified even the original advocates of these policies In 1929 he expelled Trotsky from the U.S.S.R. and forced all opposition leaders, right and left, to surrender and "recant". He had become undisputed master of the U.S.S.R.

undusputed master of the U.S.A. 
Industrialization and Collectivization.—"We are 50 or 100 
years behind the advanced countries. We must make good this lag 
in 10 years. Either we do it or they crush us." Thus Stalin explained the purpose of industrialization to a conference of industrial managers on Feb. 4, 1931 In the course of the decade the USSR, was indeed transformed from one of the most backward states into a great in-

dustrial power, this was one of the factors which was to assure Soviet victory in World War II Stalin emphatically insisted on the need to develop primarily the heavy industries Industrialization was condevelop primarily the neavy industries industrialization was con-sequently accompanied by an extreme scarcity of consumer goods and by widespread popular discontent. Stalin violently suppressed the discontent. With utmost determination be enforced a policy of in-centive rewards to skilled workers, technicians and administrators. which provoked much indignation among party members brought up in an egalitarian spirit They denounced Stalin as the leader of new

privileged social groups Industrialization on the gigantic scale envisaged in the successive five-year plans encountered many other difficulties which would have haffled and defeated a government less ruthless than Staln's In the 1930s alone about 25,000,000 muzhiks were forcibly shifted from rural areas to the industrial centres and transformed into factory workers by means of intensive training and with the help of an extremely harsh industrial discipline Throughout the Stalin era the USSR's inban population grew by about 45,000,000. In order to free labour for industry and to secure food for the swelling urban population, Stalin dustry and to secule food of the swelling urotan population, Stain collectivized farming. In 1929 there were about 25,000,000 primitive rural smallholdings in the USSR. In 1952 there were 100,000 large and highly mechanized collective farms. The peasantry at first bittelly resisted collectivization. Stallin broke its resistance and ordered the resisted collectivization Stain broke its resistance and ordered the deportation of many "kulaks" into the notorious labour camps Despite mittel failures and famines, the new system of farming achieved a high

character Foreign Policy Prior to 1941.—The national crasis which Stalin feated was approaching with World War II. Since Hitler's use to power Stalin grappied with the dilemma between an ant-Hitler condition, but the west and sugreement with Hitler. At first his diplomacy ammed at building up the anti-Hitler coalition, but finding the west reluctant to communities if to an allanace with the USS R, Stalin instel at his radiness to come to terms with Hitler in a speech at the 20th at his readiness to come to terms with Filter in a speech at the 18th party congress in March 1939. In August he struck the bargain with Hitler under which the USSR and Germany divided their spheres of influence in eastern Europe and the USSR avoided immediate

attitude of the Communist International. After a long sense of purges and expulsions Stalin succeeded in transforming the International in a "monolithic" organization, identifying the international into and expulsions Stains succeeded in transforming the Intensational into a "monolathic" organization, identifying the intensit of world Common and Common as the ally. In 1913-29 the Community parties organized the "popular alliles against Hitler. In 1913 pile plet Intensity of the Ribberton-Mojotov pact. German attack on the US S.R., stated on General Issuino—The common attack on the US S.R., stated on Common and Common attack on the US S.R., stated on o

Generalissino.—The German attack on the USSR, statted on June 2; 1945, exquirt Stahu nuaware, as he himself later pubbley admitted In preparation for critical times he had assumed the premieration of May 6; but he still inspet do be also to postpose the man attack he formed the state defense committee consisting of him-self, V M Modelov, G M Malenkov, L P Beria and K. E Voroshlov On July 3, 1944, he made the famous call on the Sowet people to "worth the earth" occupied by the invader "In occupied regions conditions must be made unbearable for the enemy and all his ac-complices. They must be hounded and annihilated a cevery step, and

complices. They must be nounced seria simulations as a very every must their neutron for all their measures frustrated. Throughout World War II Stalin was personally responsible for the major military and diplomatic decisions of his government, although he left considerable freedom of mustive to his generals. After third principle of confusion, his strategy, following the traditional Russianal Properties of the properties sian pattern of 1812, was to withdraw, to conserve strength, to gather new reserves and to force the attacker to spend his impetus and extend his lines—only after that could the USSR pass to the offensive. He his lines—only after that could the USSR, pass to the offensive. He daplayed extraordinary will power tenactivy and coolbeadedness. He stayed on in the Kremlin when Hilder's armies stood at the gates of Moscow and the Sovet government was evacuated to Kubbyshev. From the Kremlin he organized a hasty yet effective evacuation from the threatment areas of industrial plants and of many millions of industrial workers. The shifting of industry from west to east enabled the USSR, to recover from the first blows and to badid up a new and enormous armed power.

and enormous armed power.

Skalin's political conduct of the war was characterized by strong emphasis on Russian patriotism, nationalism and traditionalism. Evokaming the memorase of 1823, be described the struggle as the Great Fatherland War, and he extolled the national heroes of Mother Russia and the millitary traditions of Peter the Great, Suvorov and Kutuzov.

He rehabilitated the Orthodox Church and disbanded the Communist International These moves, dictated primarily by considerations of domestic policy, were calculated to meet the needs of his foreign policy as well. He was anxious to preserve the alliance with the western powers, and his conduct of the war in a nationalist lather than in a revolutionary spirit helped to keep the grand alliance together, despite

inner contradictions and tensions nner contiductions and tensions
Some of the tensions were due to the fact that the western Allies
repeatedly postponed the opening of the "second front" in western
Europe This was the main point in Stain's controverses, with Winston
Churchill in 1942-33. But as the Sovlet army bioké Germany's military power in the "ten offensives" which followed the battle of Staingrad in 1943, this issue lost importance. The course of the war revealed a profound shift in the international balance of power, a shift due gand 1545, this was the superintendent before or the was the control of the property of the pr

writers, musicians, linguists, philosophers and others were made to accept his judgment as final Underlying the bizarre cult were Stalin's accept his judgment as final Underlying the bizarre cuit were Stalin's middibatable achievements. He was the originator of planned economy, he found Russa working with wooden plaws and left it equipped with was marred by the despotsma nod cruelly of his dictationship, and the partrarchal character of his rule, suited perhaps to the mentality of all militarets and backward people, became an anachronism in the industrialized and moderner Russa of his own making.

Stalin's personal role in the conduct of Sowich foreign policy from

Stalins's personal role in the conduct of Struct foreign poley from 1945 to 1943 remained somewhat obscure Communists and anti-Communists alike had seen in him the architect of the revolutions in estern Europe and Chuna In the light of even the senalty documentary information available, this view officers to be illfounded. From the start Europe and the property of the community strategy and tactics in Chuna. On the other hand, he undoubtedly mapped some of the Community revolutions are seatern Europe, and and the community revolution are seatern Europe, and and these which he had obstructed, to adopt the Stalin cult. Dump has sty expra a struggle apparently developed in his entourage between the dis-hards of Stalinsan and those who stood for domestic reform, and also between adherents of a "Gough" foreign policy and advocates and to shape Soviet policy as the resultant of the conflicting trends

trends

He died from cerebral hasmorrhage in the Kremlin on March 5, 1953, at the age of 73—one of the most complex, powerful and controversal fagures in wording to the most complex, powerful and controversal fagures in wording to the first control of the contr

both banks of the lower Volga. Area 52,278 sq mi. Pop. (1939) 2,289,049 (rural 1,396,292; urban 892,757). It is a low-lying area. and the banks of the Volga for some distance on either side of the river are below sea level. The soils on the left bank of the Volga river are salt steppe; on the right, as far as the Don river, they are light brown and gray steppe, with salt efflorescences, while west of the Don is a fertile black-earth re-

The climate is continental and the rainfall scanty and variable from year to year. The region lies in an area subject to terrible recurrent famines due to failure of rainfall, and rapid desiccation has been in progress for some time. In years of sufficient rainfall, the harvest is fairly good. The chief crops are summer wheat and winter rye; millet, sunflower seed, barley, oats and potatoes are grown in less quantity, and vineyards are profitable in the south. Maize cultivation is steadily increasing, Irrigation is the only hope for the district. Experimental stations are working at Stalingrad and at Tingutin.

The most favourable region is the alluvial strip near the Volga and Akhtuba rivers, which is particularly wide near the town of Stalingrad Here the temperature remains above freezing point for nine months in the year and the combination of alluvial soil, warmth and moisture makes grain, fruit and vegetable growing very profitable Poplar trees attain a remarkable growth in ten years, and fruit trees bear for five years in succession. The nearness of the oil wells facilitates the use of internal combustion motors for irrigation purposes, and cheap and convenient routes for export are available. The drawback is the frequent change in direction of the main watercourses and their connecting channels, which may convert a fertile garden into a waste of river mud, or even wash it entirely away Dikes are being built to lessen this danger Sheep, cattle, pigs and horses are bied, and in the years after World War I made rapid progress toward restoration to prewar level. The 1921 famine, particularly disastrous in this region, following on the civil war centring round the town of Stalingrad, had reduced their numbers catastrophically. There is also some camel breeding in the district. Stalingrad is becoming a centre for timber but apart from Stalingrad (qv), there are no ind centre in timele, use part 1 oris Salangian (original properties of the part 1 oris Salangian (original properties of the part 1 oris Salangian (original properties original properties original protection and protection original protection origin barked on a scheme to construct a canal linking the two rivers. This was successfully carried out

was successfully called out in the 5th century by the Finne-Turkle Bulgars, who were in the 15th century driven northward by the Khazars, a closely selated tribe. Later the region formed a part of the empire of the Tatar Golden Horde, one section of which was consent and the selection of the control of the selection 
STALINGRAD (formerly Tsaritsyn), a town of the Russian SF SR, the administrative centre of the region. Its position at the point where the Volga most nearly approaches the Don gave it great importance as a transshipment centre, and after the construction of the railway systems of Moscow and Leningrad, its growth was rapid. The town manufactures metal goods and machinery, has an anpithar-enfining factory, a osawnills, chemical factories, breweries, a confectionery industry and mineral oil works. It is a miportant centre of tractor construction. Pop. (1939) 445,476.

A fort was erected there in 1589, after the fall of Astrakhan, or prevent the randing of settlers by Kalmucks, Kirghiz and Circassans, often joined by Cossacks and runaway serfs. The town took part in the rising in favour of the false Demetrius, and was captured by Stenka Razin in 1670. In 1773-75 it took part in the rebellion of Pugachev. After the revolution of 1597, Stalin held the town against the counterrevolutionary White army, and it was renamed in his honour.

it was renamed in his honour.

Skallagrad was the scene of violent fighting during World War II.

The Germans attacked the city in Aug 7542 and in the next months in the control of the city of the c

STALINO, a town in the Ukrainian S.S.R. Pop. (1930) 463-395. In 1870 a British subject named Hughes received a concession from the Russian government to manufacture iron rails. His company started operations on the site of the present Stalino, formerly known as Hughesovka (Yuzovka). British, French and Belgian capital was freely invested in the development of the industry from 1880 up to 1914. The close conjunction of the

Donetz coal field to non and manganese deposits made the industry very profitable. Following the 1917 revolution the industry was depressed, but from 1924 onward progress was rapid and the population of Stalino doubled between 1923-26.

STALL, literally a place where one may stand, and so applied to a separate division in a stable, shed, etc, in which a single horse, cow or other domestic animal may be kept, to a separate booth, bench or table in a market or other building, or in the street, on which goods are exposed for sale, and in England to the higher-priced seats on the ground floor of a theatre In cathedrals, monastic churches and the larger parish churches the stalls are fixed seats enclosed at the back and separated at the sides by high projecting arms, and placed in one or more rows on the north and south sides of the choir or chancel in a cathedral the canons and prebendaries have each a stall assigned to them. In the chapels of the various knightly orders the stalls are assigned to the members of the order, thus, in St. George's Chapel, Windsor, are the stalls of the Knights of the Gaiter, in Henry VII's chapel in Westminster abbey are those of the Knights of the Bath, adoined with the stall plates emblazoned with the arms of the knight occupying the stall, above which is suspended his banner Architecturally considered, the stalls of a cathedral or church are a marked feature of the interior adornment. They are richly carved, and are frequently surmounted by canopies of tabernacle work. The seats generally can be folded back so as to allow the occupant to stand upright or kneel; beneath the seat, especially in monastic churches, is fixed a small bracket, a miserere (see MISERICORD), which affords a slight rest for the person while standing Among specimens of carved stalls may be mentioned the Early Decorated stalls in Winchester cathedral (1206); the Early Perpendicular ones in Lincoln minster (c 1370); the early 15th-century canopies in Norwich cathedral (15th century), and the towering corner-stalls with their ornate carving filled with figures, in Amiens cathedral (1508-20)

STALLBAUM, JOHANN GOTTFRIED (1793-1861), German classical schoiar, was born at Zasach, near Deltzsch in asxmy on Sept. 25, 1793, and died at Leipag, where he was rector of the Thomasschule, on Jan. 24, 1861. His reputation rests upon his work on Plato, of which he published two complete editions, See C. H. Lipsius in the Osterprogramm of the Thomasschule (1863); R. Hoche in Allgemena deustiche Borgophie, vol. xxv.

STALYBRIDGE, multipla borough in the Stalybridge and Hyde parliamentary division of Chebine, England, 7; mi. E of Manchester Pop. (1951) 19,531 Area, 5 sq. mi. The whole district is densely populated Stalybridge so en of the oldest cotton towns, the first cotton mil having been elected in 176 It was incorporated in 1857 and was a parliamentary borough from 1867 to 1918. Cotton is the principal industry, but there

are also machine works, iron foundries and nail works. STAMBOLISKY, ALEKSANDR (1879-1923), Bulgarian statesman, was born at Slavovitsa, Bulgaria, Sept. 1, 1879. He attended the agricultural college of Halle in Germany. On returning to Bulgaria, aged 18, he took up journalism, and in 1902 became editor of the organ of the newly-formed Agrarian league. Six years later he was elected to the Sobranye, where he led the Agrarian party. He now began to organize the peasant masses, who form 80% of the population of Bulgaria, into agricultural associations. In 1911, when the Grand Sobranye met at Trnovo to amend the constitution, his first conflict with King Ferdinand occurred After the treaty of Bucharest (1913), Stambolisky and the Agrarians were unmerciful in their criticisms of Ferdinand's policy, though deterred from extreme measures by fear of external complications. His opposition to Ferdmand came to a head in 1915 during the negotiations that preceded Bulgaria's entry into World War I. Stambolisky strongly backed the Entente in spite of the king's anger, pressure from the government and the growing influence of the Central Powers. Summoned before the king, Stambolisky threatened him with personal violence if he should fight against the Allies, reminding him that he had a crown to lose. Ferdinand ordered his arrest. He was tried by court martial and condemned to penal servitude for life.

In Sept, 1918, when the resistance of the Bulgarian troops

began to slacken, Ferdinand released Stambolisky, who left for Bulgaria, held elections for the Sobranye, despite the interdict the Macedonian front. He returned at the head of the insurtectionary troops and their arrival at Sofia tesulted in Ferdinand's abdication and flight A partisan of the new ruler. King Bous. Stambolisky became a member of the calinet in Lin 1019 and prime minister in Oct, as head of the government he went to Paris and signed the treaty of Neurlly in the same year In Feb 1920 he dissolved the Sobranye, and the following month was returned to power at the head of a homogeneous Agiarian majority From 1920 to 1923, the Agranans under Stamholisky ruled Bulgaria with a rod of iron They had the Radoslavoy cabinet, which had brought Bulgana into World War I. condemned to death by popular vote. Stambolisky also carried measures based on the interest of the peasants (see Bulmeasures based of carea, carea, and declared "Sofia, that Sodom, that Gomorrah, may disampea! I shall not weep for her" Through his influence postwar Bulgaria loyally carried out the terms of the peace treaty, won the esteem of the Alhes, and secured a reduction of reparations Stambolisky also made persistent efforts to improve Bulgaria's relations with Yugoslavia, with which country he concluded an agreement at Nis (1922) His ultimate ideal was probably some kind of federal south Slav state, embracing Bulgaria

The overthrow of the government by a military faction on Tune o. 1923, was caused partly by dissatisfaction with Stambolisky's domestic policy and partly by the influence of the Macedonian party. The change of regime took place in one night, the Agrarian ministers being arrested in their homes. Stambolisky, pursued by an armed detachment to his native village of Slavovitsa, escaped and fled across the mountains, hoping to reach the frontier After being followed by soldiers for three days, he was eventually surrounded and shot on June 12 A formidable personality, attractive in many ways, and made of finer clay than the average Balkan statesman, Stambolisky has been called a modern Rienzi Tall and broad, his demeanour was fierce and his movements ungainly, his rough-hewn face was crowned by a mass of black hair, he impressed everyone with his strength and the sincerity of his advocacy of a "Green International," to unite the peasants of all countries Stambolisky published Authority. Anarchy and Democracy and What a Politician Ought To Be.

STAMBULOV, STEFAN (1854-1895), Bulgarian statesman, was born on Jan 31, 1854, at Tinovo, the ancient Bulgarian capital, where his father kept a small inn. He entered the seminary of Odessa in order to prepare for the priesthood but was expelled for his association with Nihilists, and, making his way to Rumania, he entered into close relations with the Bulgarian revolutionary committees at Bucharest and Giurgiu. In 1875, though only 20 years of age, he led an insurrectionary movement at Nova Zagora in Bulgaria, and in the following year organized another rising at Orekhovitsa In the autumn of 1876 he took part as a volunteer in the Serbian campaign against Turkey, and subsequently joined the Bulgarian irregular contingent with the Russian army in the war of 1877-78 After the signature of the Berlin treaty in 1878 Stambulov settled at Trnovo as a lawyer, and was soon elected to the Sobianye, of which he became president in 1884 The revolution of Plovdiv, which brought about the union of Bulgaria with eastern Rumelia, took place on Sept. 18, 1885, and it was largely owing to Stambulov's urging that Prince Alexander decided to identify himself with the movement. War with Serbia followed, and Stambulov served as an ordinary soldier in the Bulgarian army

After the abduction of Prince Alexander (Aug. 21, 1886), Stambulov, who was then at Trnovo, established a loyal government there, issued a manifesto to the nation, nominated his brother-inlaw, Gen. Sava Mutkurov, commander in chief of the army, and invited the prince to return to Bulgaria. These measures resulted in the downfall of the provisional government set up by the Russophil party at Sofia. On the abdication of Prince Alexander (Sept. 8) Stambulov became head of a council of regency, with Mutkurov and Petko Karavelov as his colleagues; the latter, however, soon made way for Zhivkov, a friend and fellow townsman of the first regent. Stambulov frustrated the mission of Gen. Nikolay Kaulbars, whom the tsar dispatched as special commissioner to

of Russia, and eventually secured the election of Prince Ferdinand of Cobus to the vacant throne (July 7, 1887) Under the newlyelected ruler he became prime minister and minister of the interior, and continued in office for nearly seven years. The aim of his foreign policy was to obtain the recognition of Prince Ferdinand, and to win the support of the Tuple Alliance and Great Britain against Russian interference in Bulgaria. He gained the confidence of the Sublime Porte, and obtained concessions for the Bulgarian episcopate in Macedonia (see Macedonia) With the assistance of Austria-Hungary and Great Britain he negotiated large foreign loans which enabled him to develop the military strength of Bulgaria

Stambulov's rule was despotic. He ruthlessly stamped out recurrent plots and armed risings engineered by equally ruthless political opponents with close support from influential Panslavist quarters in Russia. There was no clear distinction between party strife and sedition. Stambulov used his police, and sometimes the army, to deal with either Maj Konstantin Panitsa, after a conspiracy, was shot at Sona in 1890, four political opponents were hanged in the following year, and Karavelov was sentenced to five years' imprisonment. Among the deadliest enemies of the regime were the Macedonian committees, whose effective part in the struggle was emphasized by the assassination of Stambulov's colleague Belchev, in 1891, and of the Bulgarian representative in Constantinople, Vlkovich, in 1892

The arrogant way in which Stambulov used his practically unlimited power, and the growing violence of the opposition throughout the country, became intolerable to Prince Ferdinand who, moreover, wanted an accommodation with Russia. He contrived to get his unmanageable premier to resign, and accepted his resignation in May 1894. Stambulov was now exposed to the vengeance of his enemies On July 15, 1805, he was attacked and barbarously mutilated by a band of Macedonian assassins in the streets of Sona. and succumbed to his injuries three days later. His funeral was interrupted by disgraceful riots, and an effort was made to perpetrate an outrage on his remains No attempt was made to arrest his murderers; two persons, however, arraigned for the crime in 1806, were subjected to almost nominal penalties

(JDB; NIM)

STAMFORD, a municipal borough in the parts of Kesteven. Lincolnshire, Eng, on the River Welland, the boundary between Lincolnshire and Northamptonshire. Pop (1951) 10,899 Area 3 sq.mi. It has 11 mi, NW of Peterborough in the Rutland and Stamford pathamentary division. Stamford is a very ancient market town, built of local gray stone and once famous for its cloth Its position on the Great North road and on the borders of the Fens contributed to its importance. Its modern industries include general and agricultural engineering, brick and tilemaking and the manufacture of plastics and toys Of the old churches six remain; St Mary's with a Decorated spire, All Saints with fine brasses, and St. Martin's which contains the Burghley tombs, are the most noteworthy. There are remains of the 7th-century Benedictine priory of St Leonard and a west gate of the Carmelite monastery (1291). Browne's hospital is one of the almshouses known as Calises, from the wool merchants of Calais. There was a Danish fort at Stamford, which later became one of the five Danish boroughs A charter of Edgar dated A.D. 972 mentions a market and a mint. In the reign of Edward the Confessor Stamford was a royal borough governed by 12 lawmen. The Norman castle was built before 1086. Henry III gave the town a charter in 1256 and it was incorporated in 1461-62.

Stamford was known for its wool trade, its churches and its monastic schools, and in 1333 was chosen as the headquarters of the students who seceded from Oxford. An Early Decorated doorway (1300) remains of Brasenose hall The attempt to establish a regular university was prohibited by royal authority. The history of the place centred around the family of Cecil when the great Lord Burghley built Burghley house (1577-85), a fine quadrangular mansion south of the town, now the seat of the marquess of Exeter The house contains notable art collections

STAMFORD, a city of Connecticut, U.S.A., on Long Island

sound and U S highway 1. The city is served by the New York, New Haven and Hartford nalway Pop (1950) 74,293, 1940 federal census 47,938. The city still has the charm of a New England village. It is a residential suburb, with numerous trains daily to and from New York. It is also an important industrial centre. The town of Stamiond (known the first yeab by the Indian name of Rippowam) was settled in 1641 by 29 persons who seceded from the Wethersfield church. In 1662 it submitted to Connecticut. The brough was incorporated in 1830 and in 1949 town and city

governments were consolidated STAMITZ, JOHANN WENZL ANTON (1717-1757). the eldest and most important of a family of Bohemian musicians famous in the 18th century He was born at Deutschbiod on Tune 10, 1717. He was a solo violinist at the coronation of the emperor Charles VII (1742), and in 1745 the elector took him to Mannheim as director of the chamber of music. Stamitz and his successors are known as the Mannheim school. Although Phillip Emanuel Bach in Berhn and the young school in Vienna were arriving at similar results, it seems certain that Stamitz was the real pioneer, who not only demonstrated the dramatic value of the "working-out" section of the first movement of a sonata or symphony, but, by incorporating the minuet, definitely established the four-movement form. In addition he demanded of the orchestra a greater independence from the different instruments, singling out the much neglected viola. He died at Mannheim on March 30, 1757. His works include 27 concertos, sonatas and solos for violin, several sets of symphonies, and harpsichord music, Johann's brother Anton THADDAEUS STAMITZ (1721-1768) was a 'cellist at Mannheim

Much confusion has arisen between Johann and his eldest son CARL STAMIZ (1746-1801), who sometimes used the name Johann, while the father was frequently called Johann Carl or Carl Johann Earl on Experiment of the Johann Carl or Larl Johann Earl or Service of the Johann Carl or Larl Service of the Johann Carl of Larl Service of the Johann Carl of Larl Service of the Johann Carl Order of Larl Service of Larl Servi

BEBLEGGRAPHY—An introduction with details of the family, by Hugo Remain, a included, together with a thematic catalogue of a gyspirrobinstant in Beyern, and other compositions of Johann and Carl are found in series VII, 5. Van ad VVI of the same work. See also Grove, Jottonary of Music and Musician; Remain, Levikon; Eitner, Guellen-Levikon, R. Soudichiener, 'Thormale Enticything der volkgeschiehtig, p. 316 dt steg. (1926).

STAMMERING or STUTTERING, a spasmodic affection of the organs of speech in which the articulation of words is addedily checked and a pause ensues, often followed by a repetition in rapid sequence of the particular sound at which the stopping occurred. There are many grades, from a slight inability to pronounce with ease certain letters or syllables, to a condition mush which the muscles, not only of the tongue and throat and face, but even of those of respiration are involved in sosam.

In normal speech exquisite co-ordination of muscular movement is necessary in larynx, cheeks, tongue, lips, involving also complicated nervous actions. It is when the co-ordination is not effected with sufficient precision that stammering results Stammering rately shows itself before the age of four or five, and may develop in a child with some physical or psychical disorder.

Stammerers, as a rule, find the explosive consonants b, p, d, k and hard  $\xi$  the most difficult to articulate, but many also are unable easily to deal with the more continuous consonants, such as p, f, kb, s, s, kh, m, n, p, and in severe cases even the vowels are cause as certain amount of sparm. Usually the defect is not observed in whispering or singing.

The condition named aphthongia totally prevents speech, and may, at intervals, come on when the person attempts to speak; it is only temporary, and is usually caused by nervous excitement.

Stuttering may, it seems, be overcome in some cases by instrucion in reading and speaking slowly and deliberately, carefully pronouncing each syllable. When feeling the tendency to stammer, the speaker should pause, and then by a strong voluntary effort attempt to pronounce the word. He should also be taught how to

regulate respiration during speech, so that he may not fail from want of breath. In some cases and may be obtained by raising the voice toward the close of the sentence. Sounds or combinations of sounds that present speecial difficulties should be carefully studied, and the defect may be largely overcome by a series of graduated exercises in reading. Intoming is often useful. Some maintain that benefit from such education is often merely temporary. In any case the psychical basis of stammering calls for the most pronounced attention in treatment. In very severe cases, where the seizules affect other muscles than those of articulation, medical treatment is necessary.

STAMMLER, RUDOLPH (1856-1938), German jurnst and legal philosopher, was born on Feb. 19, 1856, in Alsfeld (Hessen) He was professor of law in Marburg (from 1882), Gressen, Halle and Berin (1916-21). He broke the dominance of legal poststivism and historiusm, directed legal philosophy toward nee-Kantian ideas and became the most influential legal philosophe of the early each century, especially in Germany, Spain and Latin America Stammler died April 25, 1938.

STAMP, JOSIAH CHARLES STAMP, 15T BARON, CT

1938 (1880-1941), British economist, was born in London June 21. 1880 Educated at the University of London, he entered the inland revenue department in 1896 and was assistant secretary to the board from 1916 until 1919, when he joined Nobel Industries Ltd, of which he was a director and secretary until he accepted the new post of president of the executive of the London, Midland and Scottish railway in 1925 Stamp sat on the royal commission on income tax (1919); on the finance arbitration committee for Northern Ireland (1923-24); on the committee on taxation and national debt (1924); on the Dawes Committee on German currency and finance (1924); on the court of enquiry into the coal industry (1925); and on the Paris committee of enquity into the reparations question of 1929 He was created K.B E in 1920. GBE. in 1924, and GCB in 1935, and was awarded the OM in 1936. He was the author of many books. He and Lady Stamp were killed in a German air raid on London, April 16, 1041

STAMP ACT, in American history, an act introduced by George Grenville, and passed by the British parlament in 1765, with the object of rusing revenue to pay in part the expenses of the French and Indian Wars (q.v.) It involved an extension of the British system of stamp duties to the American colonies and provided for the appointment of officials to distribute the stamp dupers. The act set stamp duties on every "skin or piece of veillum or parchment, or sheet or piece of paper" used for legal documents, academic degrees, luquor hiences, various commercial instruments, academic degrees, hugor hiences, various commercial instruments, academic hierarchical control of the page of the control of the page of th

The act was passed without debate and with no idea that it would be opposed. Determined opposition, however, was at once shown in all the colonies. It led to the passage of resolutions of protest by many of the colonial assemblies and to the calling of a Stamp Act congress in New York attended by delegates from nine of the colonies. In a resolution of Oct. 19, 1765, the Stamp Act congress declared that the Stamp act and other measures extended "the jurisdiction of the courts of Admiralty beyond its ancient limits . . ." and had "a manifest tendency to subvert the rights and liberties of the colonists." It was further resolved that "it is inseparably essential to the freedom of a people, and the undoubted right of Englishmen, that no taxes be imposed on them but with their own consent, given personally or by their representatives" and that "the people of these colonies are not, and from their local circumstances cannot be, represented in the House of Commons in Great Britain."

So great was the opposition that the proceeds from the duty were less than the expenses of collection. The next year parliament repealed the act as a matter of expediency but passed another act declaring the right of parliament to bind the colonies by its enactments.

The Stamp act was one of the important causes of the American Revolution (see United States: History)

STAMP DUTY, a tax imposed in Great Britain on written

documents which are evidence of legal rights involved. The payment of the tax is denoted by a stamp which is impressed on or affixed to the document

The Stamp act of 1891 remained the principal act governing stamp duties, though new duties and increases were authorized by successive finance acts

The sanction of the act was expressed in very wide terms. It was required that, except in criminal proceedings, an unstamped instrument executed in Great Britam, or relating, wherever executed, to any matter or thing done or to be done in Great Britam, was not to be given in evidence or to be available for any purpose whitsoever, and all judical officers before whom such an instrument was tendered in evidence were required to take notice of the absence or insufficiency of duty.

Further, any person whose duty it was to enrol or record an instrument hable to duty was made hable to a fine if he enrolled or recorded an instrument insufficiently stamped. In some instances, moreover, parties could execuse no discretion to dispesse with written evidence. For example, contracts for matrance (manne, life or general accident) were required to be expressed in the form of a stamped policy, failure to do this not only vitating the contract but rendering the parties liable to fines On the other hand, the stamp does not add to or warrant its

legality, it merely makes it possible for the legality to be examined STAMPINGS, DROP: see Pressed Metal.

STAMPS: see Post and Postal Services and Philately. STANCIOFF, DIMITRI (1864-). Bulgarian diplomatist, was born at Sistov, Bulgaria, in May 1864, and studied at the Theresianum college, Vienna In 1887 he entered the foreign office. Sofia. and was a member of the delegation entiusted with electing Ferdinand, in due course becoming head of the new king's political cabinet Afterward he was successively Bulgarian representative at Bucharest, Vienna and St. Petersburg. He became minister of foreign affairs in 1906 and was for a time prime minister after the murder of Petkoff. In 1908 he resigned and became minister in Paris, where he remained until 1915 when he was sent to Rome. He was made a member of the Bulgarian delegation to the Paris Peace conference, and from 1920 to 1926 was Bulgaria's representative to the court of St James. Stancioff was Bulgaria's chief delegate to the first international peace conference in 1899 and was a permanent member of the International Court of

STANDARD. For the various meanings of this word see Measures and Weights; Physical Units; Dimensional Analysis, Standards, National Bureau of; Electricity; Time, Standard, Standardization.

STANDARD, BATTLE OF THE, a name given to the battle of Aug 22, 1138, near Northallerton, in which the Scottsh army, largely composed of wild and undisciplined Highlanders and Galloway Pricts under King David, was deleated by the English leves of Yorkshire and the north Midlands. The latter formed a single deep line of dismounted men in front of a chariot carrying the consecrated banners of St. Peter of York, St. John of Beverley, St. Wilfred of Ripon and St. Cuthbert of Durham. King David planned to use his nucleus of knights and archers to lead the way and open a gap in the English line, but the face pride of the claamen compelled him to give them precedence. Their headlong onset was repulsed. Left isolated except for his body-guard of knights, King David retried from the field.

See C Oman, Art of War in the Middle Ages, vol. i, pp. 390-396

STANDARDIZATION. Standardization is a continuing process to establish measurable or recognizable degrees of uniformity, accuracy or excellence, or an accepted state in that process. Man's accompishaments, great as they are in this direction, page into insignificance when compared with standards in nature. The constellations, the orbuts of the planets, the changeless normal properties of conductivity, dettidity, lasticity, hardness, permeability, refractivity, strength, or viscosity in the maternals of nature, the orbits of electrons within the atom or the structure of cells, are a few examples of the assounding standardization in nature.

Only through the standardization found in nature is It possible to recognize and classify within the same species the many kinds of plants, fishes, bards or animals. Within these kinds, individuals of plants, fishes, bards or animals. Within these kinds, individuals resemble each other in minutest detail of structure, function and labits peculiar to each. If it were not for such standardization in the human body, physicans would not know whether an individual possessed certain organs, where to look for them or how diagnose or treat disease. In fact, without nature's standards there could be no organized society, no education and no physicians; each depends upon underlying, comparable similarities.

Selectivity.—Nevertheless within all the controlled, structural framework of standards in nature, individuals develop distinguishing characteristics and diversity to stimulate the natural processes of selection and survival. The processes of natural selection, the continuation of types worthy to survive, and the resulting evolution are analogous to the effect of time and experience on the customs, ceremones, rituals, procedures, codes, laws and other standards of a people

When man converts materials to energy, as in the burning of fuel or in the interconversion of mass and energy through fission or fusion, he finds immutable laws even more awesome than the standardization of structure, characteristics and functions noted

Combinations Without Limit.—Yet with this overwhelming evidence of standards none charges natuse with monotony. A though a narrow band of spectral wave lengths forms the foundation, the available vaiations and combinations of colour to delight the eye of the observer are virtually without limit. Similarly, all of the artistry of music comes to the ear through another small group of frequencies. With these examples there is little need to mention other ranges of frequencies no less valuable such as in radio, near, the infra-red, the ultra-violet, X-rays, gamma rays and cosmic rays.

### MANMADE STANDARDIZATION

Manmade standardusation is not confined to language nor to weights, measures, money, onergy, powes, nor to other material commodities or services subject to purchase. One finds standards in folklore, mythology, legend, taboos, in social customs, exercised to the configuration of the common standards and the standards train is important to geography, hotography, chemistry, pharmasy, sately, insurance, education, games, sports, music eligibility to the professions, ethics and religions. There are standards for soils, fertilizers, seeds, fruits, vegetables, grams, meat, poultry, darry products, natural and synthetic fibres and clothing. Standards are available for all kinds of aircraft, airports, highways, bridges, building construction, air conditioning, heating, insulation, plumbing, refrigeration and roofing. There are even standards for lung and standards of success. From prenata care through burial preparation and nices man has set up standards and incorporated many of them into law.

Industrial Production.—Mass production necessitates considerable standardzation of the processes by which the product is manufactured. Success or failure of a business often depends on the ingenuity and wisdom with which standards are employed to cut costs, whether the item is purchased or manufactured. It applies to single plants or groups of plants under the same management, Standardzatton of parts also builds good will by making it possible for the purchaser to obtain replacements quickly and cheaply,

Momenclature—In the last analysis, not only specifications but most other standards, except sizes, are essentially definitions. All buying and selling in which goods do not come under the actual eye of the buyer must necessarily be based upon some sort of standard. Many such standards are unwritten, simple and crude, often being no more than a two-party understanding, such as "like the one I bought from you last time." At the other externe, all of the great commodity markets are dependent upon standards which are in most cases well worked out, are nationally accepted and used, and may even be subject to legal definition. In the absence of such standards, the buyer would himself have to judge the wheat, com, cotton or copper with his own eyes. In each case a standard enables buyer and seller, or the parties to

any other undertaking with which the standard deals, to speak the same language ment, is at least partially independent in the United States competition makes the situation less clear Standards such as those

Purchase Specifications—Buyers of quantities sufficient to warrant a witter contract have traditionally employed purchase specifications to describe characteristics as municiply as practicable and supported by tests on samples of the finished product to reveal hidden characteristics. After about 1046 "performance" specifications began to grow in flavour in order to open up a wide range of materials and competition among sellers. In the United States, by the 1505, more than 200 national organizations had actively developed and published specifications or methods of testing and inspection as a basis for buying on formal contracts. These far outnumbered standards used as a basis for marketing or methods to the contract of the properties of the contract of the

Sellers and Selling Groups .- Because machines operate more effectively with uniform raw materials, and because customers prefer uniform, dependable products, each producer of branded goods develops his own standard of excellence, even if not revealed in full detail to the public. Under the pressure of competition, he endeavours to improve the acceptability of his product, sometimes through both improved quality and lowered price. This naturally led to the development by producer groups or associations of standards for products or services as a basis for selling or marketing Some of these have become so well established that even a large purchaser finds it much easier to buy according to the usual grades, for example, no. 2 common lumber, or 12 k. gold, than to attempt substituting units of his own choice or invention Such standards underly commerce governing producers. distributors, advertisers, consumers, testing laboratories, inspection agencies, and all others concerned, and therefore are of public, not merely private, concern.

Mandatory Labelling—In the United States the Food and Drug administration has complete mandatory authority over the preparation and enforcement of minimum standards for foods, drugs and cosmetics considered fit for human consumption or use. Although it sets minimum standards, seizes foods, drugs, and cosmetics below those minimums, and is ever watchful of false statements or claims on labels, this is not properly grade labelling "Grade" implies difference in quality of a commodity.

The US department of agriculture has mandatory authority through federal statutes to establish grading standards and to inspect selected commodities such as wheat, wool and cotton. Nether the selfer not an independent agency is encouraged or permitted to assume responsibility for such grading. Inspectors must be either employees or licensees of the government. Since the bulk of these selected commodities are sold according to government grade the process might be called mandatory grade identification. During World War II meat was mandatorily grade labelled by the US. department of agriculture with a roller stamp so that each outside cut bore the grade identification. It was claimed that the cost of grading any class of meat did not exceed one-half cent a pound.

Mandatory grade labelling requires additional governmental machinery for the istablishment and promulgation of standards, for the inspection of goods, application and wording of labels, seizure and action through the courts to punish violators, all of which places a burden on all who sell, handle or buy the goods In agriculture, for example, where the number of producers runs from thousands to tens of thousands, enforcement by government may seem logical. In industrial areas involving a smaller number of repostable producers, or consumer goods moving through channels having access to testing laboratories, voluntary grade labelling or declarations of quality binding upon the seller as a part of the sales contract generally result in fewer court cases and a much smaller over-all cost burden.

In the free countries of the world, standards are generally formulated under governmental supervision after consultation with those directly engaged in the production, inspection, testing, or purchase of the goods or services concerned. The Britistiution, although supported largely by the govern-

ment, is at least partially independent. In the United States competition makes the situation less clear. Standards such as those for avaition, drugs, farm products, food, highways, precious metals and transportation, whether mandatory or voluntary, are formulated under the auspices of the federal government. In engineering and technical fields there are such private organizations as the American Standards association and the American Stociety for Testing Materials. Several hundred other national technical societies and trade associations carry on standardization activities

Voiuntary Grade Labelling —For many goods technical methods of measuring and testing to determine conformity to grade did not advance sufficiently to make grade labelling practicable Where the cost of inspection or grading is high it is not feasible. For many commodities, however, suitable methods of measuring and scoring were developed to the point where the cost became relatively minor. Meat, poultry, eggs and milk are good examples among foods of voluntary grade labelling.

To foster fair competition, facilitate trade and build good will, many industries embarked on a system of voluntary grade labelling or declarations of quality that are intentionally enforceable via civil law and therefore self-policing for commodutes such as cement lumber, plywood, shingles, steels, fuel oil, ol burners, plumbing fixtures, rating of diesel engines, power shovels and cement mixers.

National Standardizing Bodies—Except for the British Standards institution (1907), industrial standards and eveloped largely after World Wat I By the 1950 there were at least 32 mational industrial standardizing bodies in the following countries Argentina, Australa, Austra, Belgum, Brazil, Canada, Chie, China, Czechoslovakia, Demark, Finland, France, Germany, Great Britán, Greece, Hungary, Inda, Israel, Italy, Japan, Madagascar, Mexoc, the Netherlands, New Zealand, Norway, Polan, Portugal, Rumania, South Africa, Spam, Sweden, Switzerland, Urugusy, United States, and the U S S R.

International Standardization—International uniformity was attained in basic scientific nomenclature in acoustics, sero-dynamics, astronomy, biology, chemistry, electronics, geodesy, geophysics, metrology, microscopy, medicine, music, kindick, kinematics, statics and other branches of science. Parts of this work have been carried out through international congresses and others through specialized international organizations such as the International Electroctechnical commission, the International Civil Aviation organization, the International Commission on Illiumination, the International Radio Consultative committee, the Five-Power Telecommunications conference, the International Scientific Radio union, etc.

In 1926, at Basle, Switz, the International Standardization association (1.8 A.), later superseded, was established. Following World War II, national standardization [S.O.) with headquarters at Geneva (Dec. 1947) The activities of I.S.O. with headquarters at Geneva (Dec. 1947) The activities of I.S.O. with the adquarters at Geneva (Dec. 1947) The activities of I.S.O. cover a broad field in such diverse area as a photographic and acoustical standards; documentation standards for libraries including microfilm technique; and innit systems for machine parts to provide for interchangeable fits. World-wide interchangeablity was obtained in some cases; e.g., metric hall bearings and i. of min. moving pictures

International trade and cultural interchange were greatly facilitated by uniformity in fundamental scientific standards and by progress in industrial standards.

Special Fields—The assembly line in the modern automobile factory became a classical illustration of great reduction in the cost of manufacture through the use of standards and mass production methods. The standardized parts of the completed car, or radio set, or refrigerator, are not made from stock and stored in a supply bin as in earlier factory practice, but flow continuously by means of automatic conveyors from the point of finished fabrication directly to the assembly line. This involves the manufacture, either within the plant or elsewhere, of thousands of parts which must be sure to fit, conveying these parts to the exact point in the plant or schedule; fastening them together accurately at a precise rate.

Similarly, the completed cars or other units do not normally go into a warehouse, but directly to dealers. Many large automobile manufacturers do not maintain covered storage space for even a single day's production of cars

Thorough-going standardization and incentives for producing higher grades greatly enlarged the market for citius and other fruits, vegetables and farm products With the aid of the U.S. department of agriculture growers and packers market their products by standard sizes and quality grades.

Specifications for iron, steel, nonferrous metals, oils, textiles, ceramics, and many other raw and semifinished materials entering into international trade were developed in all industrial countries and came into extensive use for quality identification to promote confidence and expedite sales.

BINLIOGRAPHY — Joseph Zimmerman, ed., Standard Metal Directory, vit. (1988–196). Jesse V Coles, Standards and Labels for Consumer's Goods (1949). Maria Leach, ed., Standard Dictionary of Folklore, Mythology and Legend, vol. 1 (1949), vol. n (1950)

STANDARD OF LIVING. The precise meaning of this phrase must usually be judged from its context. In popular literature it is likely to imply the relative kind and quantity of consumer goods used. Social scientists use the phrase in a different sense and have supplementary concepts. The standard of living to them relates to conditions considered essential by a person or group The standard of consumption relates solely to consumer goods, whereas the standard of living includes many other thingslessure time, working conditions, freedom to choose consumer goods and a job. In professional literature the range of things included by the phrase is not always spelled out. At times it seems to be restricted to consumer goods. The statement that people of the U S have a high standard of hving may imply that the mass of the population has come to consider certain consumer goods as essential which are accepted in other countries as the right of a select few The concepts, level of living and of consumption, relate to existing conditions-what is experienced in contrast with what is considered essential Many so-called standard of living studies might more accurately be described as studies of consumption levels They do, of course, give indirect information about standards since use tends to determine essentiality

A few people undoubtedly have, at least for short periods of time, an excess of some of the things which they desire, in which case their level of living is higher than their standard. The standard of others may be higher than their level Vague fleeting wants for things not available may occur. These do not constitute a part of the standard It relates only to those wants which generate a strong drive for their fulfilment. Their achievement brings a marked sense of gratification and their continued lack leads to unrest and a sense of frustration.

Man has biological, social and aesthetic needs. The specific ways in which these are met are culturally determined. Inherited customs and traditions ensure continuity in a society. Nevertheless cultural change is universal, although its nature and extent differ among societies and from time to time. In the United States the experience of migration to a new environment and the mingling of people from many countries tended to increase the willingness to accept new goods. Scientific and other developments that reveal better ways of meeting recognized needs lead to qualitatively higher standards. If productivity increases at a faster rate than population, quantitatively higher standards are made possible Important changes within societies may occur. The dominance of the democratic ideal and the decreasing cost per unit of output which characterizes mass production tends to reduce class differences. The mediaeval ideal was a stable class society, stable with respect to both occupation and consumption. In it demarcations in standards of living among groups were so important that sumptuary laws existed which prohibited spending beyond one's station in life. Freedom to compete for jobs and in consumption does not entirely wipe out class lines. In a study of the class structure of U.S. communities by W. Lloyd Warner and his associates, six social classes were identified in a typical U.S. city. Differences in pattern of consumption were found that were independent of income, especially for education, housing and the automobile. These differences led to the conclusion that the standard of living of the groups differed qualitatively as well as quantitatively. The study century, the decline in the rate of population growth in industrial-

did not seveal, however, which groups were influencing most the direction of change.

Some attempts have been made to measure the extent and urgency of both met and unmet needs Attitude studies, in which people have been asked about their needs and desires, were still in an experimental stage at mid-20th century In addition, analyses have been made of change in purchases with change in income and price These led to the classification of goods as necessities and luxuries-a classification which is, however, very crude Studies over a period of time show that luxuries of one period are necessities in another; and furthermore the so-called luxuries in a given society may be looked upon as necessities by some of its

Standards of consumption affect population growth and long-run labout supply through their effect on the age of marriage and the birth rate They also affect the total labour supply in the short run in that people weigh the relative ments of more income against more lessure or more direct production for the family, they affect the labour supply in a given occupation insofar as more income and the additional consumer goods thus made possible may compensate for less pleasant work. The existence of the desire for more consumer goods is also important in inducing families to migrate Standards of living also have a bearing on the business cycle Forecasters would like to know when income falls to what extent will families cut consumption? To what extent will they decrease sayings and draw on assets in order to maintain customary consumption? And furthermore if production rises, will it find a ready market because of desires previously unmet? Or will the additional income go wholly or largely to savings? (See Consump-TION.) In the administration of a war economy or other emergency when customary levels of consumption cannot be maintained it is helpful to know where cuts will be least resented, and how best to carry on an informational program in order to make clear the need for the shortages and thus minimize unrest and frustration.

In the United States it is not uncommon for the claim to be made that the wages of husbands are madequate to provide the American standard of living, if they seek work beyond their regular job, if wives (especially those with young children) seek work outside the home or carry on industrial work in the home, or if children are taken out of school to help support the family the basis of such indices the incomes of many husbands are inadequate. Census reports show that the lower the income of husbands the higher the percentage of wives seeking gainful work

The drop in the percentage of wives working with higher incomes was more pronounced in families with children under ten years of age than in others, suggesting that a greater sacrifice is made by them in family production or in leisure in order to earn

Occupation is an important part of the standard of living Some types of work are so much preferred over others that a lower income will be accepted in lieu of a lower ranking job. Changes in income differentials during World War II in the United States brought considerable mobility of workers from more preferred to less preferred types of work. Ideas prevail based largely on customary income as to what the standard of hvmg of a given occupational group should be. Jessica Peixotto, in Getting and Spending at the Professional Standard of Living (1927), emphasized the special consumption needs of professional people, and pointed out that the desire for high consumption would attract people away from academic professions unless earnings were made more nearly comparable to those of alternative jobs. Except in industries where wages are unusually low, the need to attract workers and ability of industry to pay rather than a minimum standard of hving are the major factors of wage negotiations in the United States.

The standard of living has long been a matter of major interest to population analysts. Thomas Malthus, in his Essay on Population (1798), argued that population growth is determined by means of subsistence. He believed that it was held in check chiefly by starvation, pestilence and war, all of which were direct results of population pressure on means of subsistence. This view assumed a static standard of living By the beginning of the 20th ized countries after decades of rising productivity shifted attention to the effect of a rising standard of living. Then two tears came to be expressed (1) that tamilies in general would come to place such a high value on material goods for themselves and their children that the birth rate would fall to a point where total population would decline, and (2) that the effect of a high standard of living on the birth rate was especially marked among families with high income, thus, the quality of the population was likely to be adversely affected. An upturn of the birth rate in some western countries after the middle 1930s, however, allayed the first fear. For example, the 1950 census of the United States reported a 55% increase since 1940 in children under 5 years of age, while the total population increased by only 14%.

An increase in real income or a change in relative values or both may have played a part Joseph S Davis considered that this change may have been due to "a change in standards of living . of such a nature that mairiage and children are given a relatively higher priority in what is urgently desired, instead of continuing to lose ground to ever higher per capita consumption, comfort, and lessure" (J. S Davis, The Population Upsurge in the United States, Food Research Institute War-Peace Pamphlets No 12, Stanford University, Stanford, Calif, Dec 1949, p 57). Population analysts by 1950 also had evidence that the inverse relation of birth rate to income was tending to disappear, and that within social classes buth rate and level of income tended to be directly related. The highest birth rate was still found at the lowest income level The factors responsible for this awaited investigation, there might be a relative lack of interest in consumer goods available in the market in contrast with desire for children, or an acceptance of a low level of education for children so the cost of rearing them is low, or children might be desired as a means of security in old age, or there might be lack of knowledge of birth control methods; or an assumption might exist that society would care "adequately" for the children

Policies and programs of the United Nations brought to the torefront once more a consideration of the validity of the Malthusian doctrine. Among the nations of the world high birth lates occur where the level of consumption is low, and where death rates are high. The value system of these societies tends to stimulate high birth rates Only thus can the population be maintained in the face of high death rates. Experience indicates that industrialization brings a reduction in mortality before a decline in fertility To what extent is a decline in fertility dependent on a rising standard of hving? What is the process of bringing this about? are no clear cut answers, in spite of the experience in western countries with falling birth rates which resulted, in part, from a rising standard of hymg.

Standards of hving of individuals are a dominant driving force in a society There are, in addition, social standards of living which are the basis of many types of policies. The levels of consumption provided those in prison or on relief are, for example, an expression of a society's minimum standard for its members. Social standards are implicit in minimum wages, unemployment benefits, public old age pension systems, family allowances and the provision of various goods from public funds. In addition to individual and social standards there are normative standards provided by scientists and other specialists which are used as yardsticks in evaluating consumption

There are, for example, the recommended dietary allowances of the National Research council (1945), the major yardstick used in appraising the nutritional quality of U.S. diets. The American Public Health association, through its committee on the hygiene of housing, provided a yardstick for measuring adequacy of housing. Such standards as these are commonly utilized in formulating quantity budgets to measure the cost of a given level of consumption. The quantity of goods included in such budgets may exceed those consumed by families at the general level of the budget at the time it was prepared. Since normative standards incorporate the scientific development at a relatively early stage of its impact on consumer demand they tend to point the way in which consumption is developing. (See also Consumption; Cost of Liv-ING.

STANDARD OIL COMPANIES. These individual U S petroleum corporations were formerly a single group operating throughout the world under the stock ownership of Standard Oil Company of New Jersey, but later became separate competing enterprises. In 1911 the United States supreme court ordered the dissolution of the New Jersey company, and shares of 33 subsidianes were distributed to stockholders of that company

Thereafter there was a gradually decreasing community of interest among the different units, and ownership of the shares became widely diversified Active competition arose between certain large former Standard Oil companies in every branch of the petroleum activity, in domestic marketing territory and in foreign

As was the case with other large independent companies never associated with the Standard Oil group, tremendous growth of certain former Standard Oil companies was notable after the petroleum industry became predominantly a gasoline industry Most of the companies formerly in the Standard Oil group tended toward integration of their operations in the four major fields of production, transportation, refining and marketing. Moreover, certain companies formerly in the Standard Oil group-notably Standard Oil company (N J ), Socony-Vacuum, and the Standard Oil Company of California-became active in foreign production. transportation, refining and marketing The Socony-Vacuum Oil company resulted from a merger in 1931 of two former Standard Oil corporations, the Vacuum Oil company and the Standard Oil company of New York, a merger officially approved on the grounds that it was not a lessening of competition because the operations of the two companies were primarily in separate, complementary fields

In 1911 Standard Oil companies purchased the bulk of their domestic crude oil requirements from independent producers, and themselves were little engaged in production. But this was quickly changed as large independent crude oil producing companies built their own transportation systems and refineries and enlarged their markets. It was estimated that, by the 1950s, former Standard Oil companies were producing about 22% of U.S. crude oil production. The Standard Oil company (New Jersey) remained the largest U.S. oil company and one of the greatest U.S. industrial corporations.

Principal companies of the 1950s formerly in the Standard Oil group were: Standard Oil company (N.J.); Standard Oil company (Indiana); Socony-Vacuum Oil Co, Inc.; Standard Oil Company of California; Atlantic Refining company, Standard Oil company (Ohio); the Ohio Oil company; Standard Oil company (Kentucky); and South Penn Oil company.

STANDARD PRICE: see Price Maintenance.

STANDARDS, NATIONAL BUREAU OF. Established March 3, 1901, by an act of the congress of the U.S.A, the national bureau of standards is the principal agency of the federal government for basic and applied research in physics, mathematics, chemistry and engineering. Supplementing the enabling legislation, congress further prescribed the functions of the bureau in public law 619, July 22, 1950 Six major functions are listed. (1) maintenance and development of national standards of measurement and their application, (2) determination of physical constants and properties of materials, (3) development of methods of testing materials, structures, and mechanisms and the testing of materials, supplies and equipment, (a) scientific and technical co-operation with government and private agencies, (5) advisory services for federal agencies, and (6) invention and development of devices to serve special needs of the government. In addition to these general functions other types of activities are specifically justicized, melding research in nuclear physics, radio propagation, and mathematics as well as the classic divisions of the physical sciences.

The bureau is organized into sections, grouped according to subject matter into 15 major divisions: electricity, optics and metrology, heat and power, atomic and radiation physics, chemistry, mechanics, organic and fibrous materials, metallurgy, nuneral poducts, building technology, mathematics, electronics, ordanic missiles and radio propagation. The principal laboratories are in Washington, D. C. Field stations were maintained in 15 states in the 1956s, while 5 stations were outside the continental limits of the United States.

The basic research of the bureau is related to scientific standards and measurements. Continued research is conducted even in fields often assumed statuc (e.g., length and time standards) in response to new or anticipated developments in other fields of science. Thus, the bureau developed atomic standards of length and time in order to provide more precise measurements needed in atomic and nuclear physics and high frequency communications. The bureau's first atomic clock, based on the utilization of the constant frequency of wheration of the atoms in ammonia, provided a time constancy of one part in 1,000,000,000,000 appears feasible. Two new clocks—one using ammonia, the other using acessum—were later developed. New measurements of the magnetic moment of the proton promise to yield an atomic standard of mass in the future.

Major projects unvolving pute and applied research and development are undertaken in accordance with needs of the federal government. Extensive work was under way, in the 1950s, in stonic and nuclear physics. The atomic bomb project was initiated by the bureau, upon presidential request, in 1950, and work in this area was expanded to mclude nonunitary aspects, particularly in the field of ladinactive isotopes. Contributions to the national defense also included projects in ordinance and missale devices. The only successfully used guided missile of World War II—the BAT —was developed by the bureau, which was also responsible for the basic proximity fuze for nonrotating projectiles. The development of special optical glasses, synthetic mica, radio beacons, and the instrument landing system (ILS) for blund landing of aircraft were other typical projects of a specific nature

The manifold expansion of the nuto-frequency spectrum after World War II created many problems concerning the behavour and properties of high-frequency radio waves. Extensive studies of the ionesphere, of ionospheric propagation, ground effects, and climatological factors have been conducted. These studies had direct applicability to commercial radio and television One phase of this work included continuous monitoring of the ionosphere at various locations around the world, providing the bass for predictions of the best frequencies to use at any time and place. These predictions are issued for a one-month period, there months

In mathematics considerable progress was achieved in numerical analysis—e.g., the general problem of finding eigenvalues of matrices and systems of differential equations and methods of solution for the partial differential equations of physics—in the compliation of specialized mathematical tables, in the application of modern statistical inference to complex engineering and sampling problems, and in the study of theory of samples consisting of small numbers of specimens. The increasing importance of mathematics in nuclear physics and aerodynamics, for analytical reasons as well as economy, led the bureau into the field of electronic comouters.

SÉAC—the National Bureau of Standards Eastern Automatic Computer—was completed in 1950 and continued in operation, day and night, on problems in the physical sciences, management, and machine experimentation. SEAC was the fastest generalpurpose, automatically sequenced electionic computer in operation up to that date A second machine—SWAC—was constructed later, and the bureau has also sponsored computer development projects by industry.

The work of the hureau of duect interest to the general public has to do with standards of measurement. The ordinary standards of weights and measures used by the public and industry, and which affect every commercial transaction, are dependent upon the basic work of the bureau Every instrument-ranging from the electric meters in households to altitude indicators on supersonic aircraftdepends on the bureau's standards, measurements, and calibrations for its precision and accuracy Safety codes and safety measures concerned with housing, plumbing, electricity, fire, X-ray, radioactive isotopes, elevators, 14dio, etc., are developed by the bureau Extensive studies of building materials and structures have been pursued Studies of dental materials, hospital equipment, surgical tools, the structure of the human skeleton, cutting of tissue for microscopic examination, and synthetic blood plasma are typical of the work conducted by the bureau in those areas of the biological sciences which have problems essentially physical in nature (See STANDARDIZATION )

The results of the bureau's work are available through a monthly periodicals (Journal of Research, Technical News Bulletin, and Busic Radio Propagation Predictions) and a series of nonperiodical publications. An indexed list of publications (Publications of the National Bureau of Standards, circular 460, 375 pp) is available from the superintendent of documents, U.S. government printing office, Washington 25, D.C. (Hit., O)

STANDERTON, a town in South Africa at the Vaal river bridges, pop. (1946) 9,277 (4,303 whites), 114 mt SE of Johannesburg, altitude 5,022 ft It is chief town of a district of the same name and the centre of an agricultural and coal-mining region.

STANDISH, MYLES or MILES (c 1584-1656), American colonist, was born, according to Nathanael Morton, in Lancashire, England, but became a soldier in the Netherlands, where he met the Pilgrim Fathers He sailed with them in the "Mayflower" in 1620, and became the captain or military defender of New Plymouth As soldier and linguist he was invaluable in dealing with the natives He rescued Weymouth colony from the Indians in 1623, returned to England on behalf of Plymouth colony in 1625-26, and later helped to buy out the Merchant Adventurers. He was treasurer of the colony 1644-49, and for a time assistant governor; but was never elected governor, perhaps because not a member of the Pilgrim Church He removed to Duxbury, 1642, where he died, 1656, and a monument was erected to him in 1872. Longfellow's well known poem, Courtship of Mylcs Standish, is based on a late tradition, published in Alden's work on Epitaphs in 1812-14

The story that Chorley Church register was defaced to defeat his title to local lands is proved to be unfounded. Myles Standish was one of the Ormskirk branch of the Standish family

See the histories of Plymouth colony by William Bradford and by Nathanael Morton Also Porteus Captain Myles Standash (1920) and History of Standash (1927) (T. C. P.)

STANDPIPE is a vertical pipe coupled to a ground hydrant, to lead off water suitably for filling buckets, street-watering pace, fire bose, watering carts, etc. The pipe is either permanent or detachable, and the top may be of fixed or swivel type, with one or more outlets. A tall hent pipe is sometimes attached for filling watering carts or small locomotives. A standpost is often combined with a drinking fountain or with a lamp column. In the United States a standpipe is a vertical pipe or high tank to which water is forced in order to obtain a better head pressure than is afforded by the mains. (See Hyddaws).

STANFIELD, WILLIAM CLARKSON (1704-1867). English marme painter, was born of Irish parentage at Sunderdad in 1794. As a youth he went to sea, but he practised sketching to such good effect that, on being incapacitated by an accident, he was able to paint scenery at the "Old Royalty," a sailors' theatre in Wellcloss Square, London, the Coburg theatre, Lambeth and at Drary Lane. His first easel exhibit was "Wreckers off Fort Rouge" at the British institution in 1827, and in 1832 he was

art was influenced by his early scene painting and tends to be spectacular and dry and hard in colour, on the other hand the treatment is broad and effective

Hs prancipal works are "Mount St Michael", "The Opening of London Bridge" and "Portsmouth Habour" (1822), "The Battle of Trafajaga" (1836) for the United Service Club, "Siola Bella" (1841), "The Victory' bearing the Body of Nelson towed into Gibraltar" (1853) and "The Abandoned" (1850). Stanfeld's Coast Scenery contains 40 of his works engraved in line

STANFORD, SIR CHARLES VILLIERS (1852-1924), Irish composer, was born in Dublin on Sept. 30, 1852. After studying in London under Ernst Pauer he won (1870) a scholarship at Queen's College, Cambridge, whence he migrated to Trin-ity College m 1873, and succeeded J. L. Hopkins as college organist, a post he held till 1892 His appointment as conductor of the Cambridge University Musical Society gave him great opportunities. In 1874 to 1877 he visited Germany each year, studying under Reinecke and Kiel His first important composition was incidental music to Tennyson's Oueen Mary (Lyceum, 1876). In 1881 his opera, The Veiled Prophet, was given at Hanover; followed by Savonarola (Hamburg and Covent Garden, 1884), and The Canterbury Pilgrims (Drury Lane, 1884). A long interval separates these from his later operas, Shamus O'Brien, the least pretending but most successful of his dramatic works (Opéra Comique, 1896) and Much Ado About Nothing (Covent Garden, 1901). Meanwhile he had been appointed professor of composition at the Royal College of Music, 1883; conductor of the Bach choir, 1885, professor of music in the university of Cambridge, succeeding Sir G. A. Macfarren, 1887; conductor of the Leeds Philharmonic Society, 1897, and of the Leeds Festival from 1901 on. He was knighted in 1902 and died in London March 29, 1924. His instrumental works include six symphonies, many chamber compositions, among them two string quartets; besides many songs, part-songs, madrigals, etc., and incidental music to the Eumenides and Oedipus Rex (as performed at Cambridge), and Tennyson's Becket. His last operatic work was The Travelling Companion, posthumously produced in 1926. His church music and editions of Irish and other songs are well known. See his Studies and Memories (1908), and Pages from an Unwritten Diary (1914).

STANFORD UNIVERSITY: see LELAND STANFORD JR.

UNIVERSITY.

STANHOPE, CHARLES STANHOPE, 3RD EARL (1753-1816), English statesman and scientist, was born on Aug 3, 1753, and educated at Eton and Geneva, where he studied mathematics. In politics he was democratic; he represented High Wycombe from 1780 until his accession to the peerage in 1786, giving his support (1783-84) to the administration of Pitt, whose sister, Lady Hester Pitt, he married in 1774; but when Pitt forsook his Liberal principles, Stanhope severed their political connection. He was the chairman of the "Revolution Society," which expressed its sympathy, in 1790, with the aims of the French Republicans, and in 1795 he introduced into the Lords a motion deprecating any interference with the internal affairs of France, on which point he was in a "minority of one." He thereupon retired from politics for five years. He spent much money on experiments in science and philosophy. His inventions include the printing press and the lens which bear his name, a monochord for tuning musical instruments, and two calculating machines. He projected a canal through Devonshire, and took the levels himself. His writings include Principles of Electricity (1779); a reply to Burke's Reflections on the French Revolution (1790); and an Essay on the rights of juries (1792). The lean and awkward figure of Lord Stanhope figured in a host of caricatures. His first wife died in 1780, and in 1781 he married Louisa, daughter and heiress of the Hon. Henry Grenville, who survived him, and died in 1829. Lady Hester Stanhope (q.v.) and Lady Lucy Rachael Stanhope, who eloped with the family apothecary and was never reconciled with her father, were daughters by his first wife. Lord Stanhope died at Chevening, Kent, on Dec. 15, 1816. See G. P Gooch, Life of Charles, 3rd Earl Stanhope (1914).

STANHOPE, LADY HESTER LUCY (1776-1839), the eldest child of the 3rd Earl Stanhope by his first wife, Lady

made A.R.A and in 1835 R.A. He died on May 18, 1867. His Hester Pitt, was born on March 12, 1776, and hved at her father's seat of Chevening in Kent until early in 1800, when his excitable and wayward disposition drove her to her grandmother's house at Burton Pynsent. In 1803 she became the chief of the household of her uncle, William Pitt Although her wit and beauty cheered his declining days, her satire created enemies. Lady Hester Stanhope possessed great business talents, and when Pitt was out of office she acted as his private secretary. On his death she was granted a pension of £1,200 a year, dating from Jan. 30, 1806 On Pitt's death she lived in Montagu Square, London, but in 1810, she left England for ever After many wanderings she settled among the Druses on Mt. Lebanon, and from the lonely villa of Djoun, 8 m. from Sidon, she wielded an almost absolute authority over the surrounding districts, maintained by her commanding character and by the belief that she possessed the gift of divination Ibrahim Pasha, when about to invade Syria in 1832, solicited her neutrality She died on June 23, 1839 Her disappointments and her dictatorship intensified a temper naturally imperious. In appearance as in voice she resembled her grandfather, the first Lord Chatham

Some years after her death there appeared three volumes of Memors of the Lady Haster Stanhope as related by herself in Conversations with her Physicana (Dr Meryon, 1843), and these were followed in the succeeding year by three volumes of Travels of Lady Hester Stanhope, formus the Completion of her Memors narrated by her Physical Physical Physical Rev. 1841. alope, forming the compension of new aemourn nutration by new rays are compension. They presented a lively picture of this strange woman's line of the compension of the compe

STANHOPE, JAMES STANHOPE, 1ST EARL (c 1673-1721), English statesman and soldier, the eldest son of Alexander Stanhope (d 1707), a son of Philip Stanhope, 1st earl of Chesterfield, was educated at Eton and Trimty college, Oxford. He served in Italy and Flanders as a volunteer against France, and in 1605 obtained a commission in the British aimy. Entering the House of Commons in 1701 he still continued his career as a soldier. In 1706 he was appointed British minister in Spain, and in 1708 commander-in-chief there. He captured Port Mahon, assisted at the battles of Almenara and Saragossa in 1710, but was forced to capitulate to the French at Bribuega on Dec o. 1710. and was imprisoned in Spain for a year.

Returning to England in 1712 he became one of the leaders of the Whig opposition in the House of Commons, and, in 1714, he became secretary of State for the southern department, sharing with Walpole the leadership of the House In 1716, as George I's foreign minister he only just failed to conclude a treaty with France He was made first lord of the Treasury in 1717, but in 1718 returned to his former office of secretary of State In 1717 he was created Viscount Stanhope of Mahon, and in 1718 Earl Stanhope. He helped to conclude the quadruple alliance between England, France, Austria and Holland (1718) He died in London on Feb. 5, 1721, just after the collapse of the South Sea scheme, for which he was partly responsible, though he did not

STANHOPE, PHILIP HENRY STANHOPE, EARL (1805-1875), English historian, better known as Lord Mahon, son of the 4th earl, was born on Jan 30, 1805, was educated at Christ Church college, Oxford, and entered parliament in 1830. His chief interest was in literature. He was a trustee of the British Museum, and in 1856 proposed the foundation of the National Portrait Gallery, whose subsequent creation was due to his executors. He also assisted in the establishment of the Historical Manuscripts Commission, and was president of the Society of Antiquaries from 1846 onwards. In 1855 he founded the Stanhope Essay prize at Oxford. His works include Life of Belisarius (1829); History of the War of Succession in Spain (1832); History of England from the Peace of Utrecht to the Peace of Versailles (1836-53); Life of William Pitt (1861-62); and History of England, comprising the reign of Queen Anne until the Peace of Utrecht (1870, new ed. 1908), the last two of which remain standard works. Stanhope had unique access to ms, authorities, a clear style, and a general impartiality in criticism He died on Dec. 24, 1875, and was succeeded by his son, Arthur Philip (1838-1905).

STANIMAKA, a town of south Bulgaria, at the foot of the Rhodope mountains. Pop. (1934), 17,817. It is a very old Greek colony, its inhabitants speak a dialect containing otherwise obsolete classical terms. On the hill above the town is "Tsar Asen's tower" This was a very strong fortress, and here Remer of Trit, the Latin Count of Philippopolis, was besieged for nine months, until relieved by Villehardouin (q v). A few miles un the valley of the Cepelare is the monastery of Backovo, the

second in Bulgaria, with a famous library.

STANISLAUS I. [Leszczynski] (1677-1766), king of Poland, born at Lemberg in 1677, was the son of Rafael Leszczynski. palatine of Posen, and Anne Catherine Jablonowska. He married Catherine Opalinska by whom he had one daughter. In 1607, as cunbearer of Poland, he signed the confirmation of the articles of election of Augustus II. In 1703 he joined the Lithuanian Confederacy against Augustus, and in the following year Charles XII. selected him to supersede Augustus, and by bribery and intimidation secured his election (July 2, 1704). A few months later Stanislaus was forced by a sudden inroad of Augustus to seek refuge in the Swedish camp, but finally on Sept. 24, 1705, was crowned king with great splendour. Stanislaus at once concluded an alliance with Charles, and rendered him some small assistance against the tsar; but he depended entirely on the success of his ally's arms, and after Poltava (1709) the vast majority of the Poles hastened to repudiate him and make their peace with Augustus, and Leszczynski, henceforth a mere pensioner of Charles XII . retreated to Swedish Pomerania. On the restoration of Augustus, Stanislaus resigned the Polish Crown (though he retained the royal title) in exchange for the little principality of Zweibrucken. residing at Weissembourg in Lorraine.

In 1725 Louis XV. of France married Stanislaus' daughter Mary, and supported his claims to the Polish throne after the death of Augustus II. in 1733, which led to the war of the Polish Succession. On Sept 9 1733 Stanislaus himself arrived at Warsaw. having travelled through central Europe disguised as a coachman, and on the 10th was once more elected king of Poland. Russia, however, protested, proclaimed the Saxon candidate king as Augustus III. (June 30, 1734), and in October besieged Stanislaus with his partisans in Danzig. The expected French help did not arrive until May 20, 1735, when a fleet disembarked a small force, which, however, could do little. On June 30 Danzig capitulated unconditionally after a stubborn resistance of 135 days. Stanislaus, disguised as a peasant, had contrived to escape two days before. He attempted to rally his partisans from Konigsberg, and to secure fresh help from France and from Count Potocki in the Ukraine, but without avail,

In 1736 Stanislaus again abdicated the throne, but received by way of compensation the dukedom of Lorraine and Bar, which was to revert to France on his death. He settled at Lunéville. founded there the Academia Stanislai, and devoted himself for the rest of his life to science and philanthropy He died in 1766 at the age of 80. Among his works may be mentioned: Ocuvres du philosophe bienfaisant (Paris, 1763; 1866).

See Robert Nishet Bain, Charles XII. (1895); Louis Lacroix, Les Opucules inédites de S. L. (Nancy, 1866); Lettres inédites de S. L., ed P. Boyé (1901); Marchioness Des Reaulx, Le Roi Stanislas et Marie Lesscynishi (1895).

STANISLAUS II. AUGUSTUS [PONIATOWSKI] (1732-1798), king of Poland, the son of Stamslaw Poniatowski, palatine of Cracow, the friend of Charles XII. of Sweden. Through the influence of his uncles the powerful Czartoryski, he was sent to St. Petersburg in the suite of the English ambassador Hanbury Williams. Subsequently, through the influence of the Russian chancellor, Bestuzhev-Ryumin, he was accredited to the Russian court as the ambassador of Saxony. Through Williams he was introduced to the grand duchess Catherine, who was irresistibly attracted to the brilliant young nobleman, for whom she abandoned her other lovers. Poniatowski was concerned in the conspiracy to set aside the succession of the grand duke Peter and his son Paul in favour of Catherine, a conspiracy frustrated by the Russian princes, which became extinct in 1340 when Casimir the

unexpected recovery of the empress Elizabeth and the consequent arrest of the conspirators.

Stanislaus returned to Warsaw much discredited, but nevertheless was (Sept. 7, 1764) elected king of Poland through the overwhelming influence of Catherine, and crowned on November 25 to the impotent disgust of his uncles. He was hated by the nobility, yet he tried to do his best. He maugurated some economical reforms. After the first partition he sought to restore the power of their country, while his eloquent oration before the Diet on taking the oath on May 3, 1791, moved the deputies to tears. But when the confederation of Targowica was formed against the constitution, he was one of the first to accede to it, in this way completely paralysing the action of the army which, under his nephew Prince Joseph and Thaddeus Kosciuszko, was performing prodigies. On the outbreak of the insurrection of 1794 he was obliged to sue for his very life to Kosciuszko, and saw his effigy expunged from the coinage a year before he was obliged to abdicate his throne. The last years of his life were employed in his sumptuous prison at St. Petersburg (where he died in 1798) in writing his memoirs. He contracted a secret marriage with the countess Grabowska. He was capable of the most romantic friendships, as witness his correspondence with Mme, Geoffrin,

slupe, as witness his correspondence with Mine. Geoffrin.

STANISLAVSKY, stage name of Constantine Sergeevich Alexeev (1863-1938), Russian theatrical producer, was born in Moscow. His father was a rich mill owner and his grandmother a French actress; he studied at the imperial school of dramatic art and in 1888 began work as an actor and producer in the Society of Art and Literature and after ten years of training founded in 1898 together with the playwight V. Nemirovitch-Dantchenko (18587-1943) the Moscow Art Theatre. His productions were varied, ranging from the historical Czar Fedor to the extreme naturalism of Chekhov's plays He was also an actor of great force and subtlety, taking the leading parts in Chekhov's and Gorky's plays. Stanislavsky revolutionized the art of producing and was the father of the modern Russian theatre.

See Stanislavsky, My Life in Art (Eng. trans., 1924). STANISLAWÓW, a province of Poland. Area 7,090 sq.mi. Pop. (1931) 1,477,000. In 1931 68 9% were Ruthemans, 22 4% Poles; the rest mostly Jews. The Ruthemans speak a different dialect from that of the Ukramans and the Polesian groups, those in the Carpathian area maintaining their Highland customs, especially the interesting tribes of Hucules, who seem to be of Rumanian admixture. They are members of the Greek Catholic or Uniat Church. The province consists of a fertile belt drained by the tributaries of the Dniester, which forms its northeast boundary, of the Carpathian slopes and the mountains themselves, which rise in height to the east and form the lofty Czarna Hora, with dense forests of beech, fir, etc. The province produces large quantities of timber, Stanislawów is famous for its horses and dairy cattle. The salt of Kolomyja has been worked since the earliest times, forming part of the salt belt which extends all along the mountains to Cracow. Potash is found at Kalusz and Turka. The Stanislawów district also has oilfields. Other districts, such as Kolomyja, produce oil and there is mineral gas at

The mountain scenery of the province is very beautiful, particularly in the valley of the Stryj. There are a number of health resorts, such as Kosów, in Pokucie. The chief towns are Stanislawów (pop. 1931, 60,000), Stryj (30,682), Kolomyja (33,385), Kalusz and Sniatyn. Halicz (Russian Galich), the ancient capital of the three provinces of Stanislawów, Tarnopol and Lwow, is a small town near the Dniester. It was the capital of a line of

Great occupied the principality The province was occupied by soviet troops in 1939 and was conquered by axis troops in 1941.

STANLEY (FAMILY), derived its name from Stanley in Leek (in the Staffordshire "moorlands") Its first known ancestor is Adam de Stanley, brother of Liulf de Audley, who lived in the time of King Stephen His descendant, Wilham de Stanley, acquired the forestership of Wirral, with an heiress, in 1284, and was ancestor of two brothers, Sir William and Sii John Stanley. The former married the heiress of Hooton in Wirral and was ancestor of the Stanleys of Hooton, whose baronetcy, created in 1661, became extinct in 1893. The younger brother, heutenant of Ireland under Richard II and Henry IV, obtained from the latter the Isle of Man in fee. His grandson Thomas was father of the first carl of Derby and of Sir William Stanley of Holt, whose great wealth led to his execution for treason in 1495, and also of Sir John Stanley, ancestor of the Stanleys of Alderley, who obtained a baronetcy in 1660 and a barony in 1839 The earls of Derby are noticed under DERBY

The barony of STANLEY OF ALDERLEY was created in 1839 for Sir John Thomas Stanley, Bart (1766-1850), of Alderley Park. EDWARD JOHN STANLEY, 2ND BARON (1802-1869), entered the House of Commons in 1831 and became under-secretary to the home department in 1841, patronage secretary to the treasury from 1835 to 1841, paymaster-general in 1841, and under-secre-tary for foreign affairs from 1846 to 1852 In 1848, two years before he succeeded to the barony of Stanley, he was created Baron Eddisbury of Winnington He was president of the board of trade from 1855 to 1858, and postmaster-general from 1860 to 1866. His wife, Henrietta Maria (1807-1805). a daughter of Henry Augustus Dillon-Lee, 13th Viscount Dillon, was a remarkable woman Before her marriage in 1826 she had hved in Florence, and had attended the receptions of the countess of Albany, the widow of Charles Edward, the Young Pretender; and in London she had great influence in social and political circles. When he was patronage secretary her husband was described by Lord Palmerston as "joint-whip with Mrs Stanley" Later in life Lady Stanley of Alderley helped to found the Women's Liberal Unionist Association, and she was a strenuous worker for the higher education of women, helping to establish Girton College, Cambridge, the Girls' Public Day School Company, and the Medical College for Women. She died in 1895.

STANLEY, ARTHUR PENRHYN (1815-1881), English divine, dean of Westminster, was born on Dec. 13, 1815, at Alderley, Cheshire, the son of Edward Stanley (1779-1849), afterwards bishop of Norwich. He was educated at Rugby under Arnold, and at Balliol college, Oxford In 1839 he was elected fellow of University college, also taking orders In 1840 he travelled in Greece and Italy, and for ten years he was tutor of his college. In 1845 he was select preacher, and published in 1847 Sermons and Essays on the Apostolic Age He was a strong advocate of toleration and used his influence to protect from formal condemnation the "Tractarian" party. In 1847 he resisted the movement set on foot at Oxford against R. D. Hampden's appointment to the bishopric of Hereford Finally, in 1850, in an article in the Edinburgh Review, in defense of the "Gorham judgment" he asserted two principles which he maintained to the end of his life-first, "that the so-called supremacy of the Crown in religious matters was in reality nothing else than the supremacy of law," and, secondly, "that the Church of England by the very condition of its being, was not High or Low, but Broad, and had always included and been meant to include, opposite and contradictory opinions."

He was greatly interested in university reform and acted as secretary to the royal commission reporting in 18-29. Stanley was also appointed to a canony at Canterbury. During his residence there he published his Memoir of his father (1851), and completed his Commentary on the Epistics to the Commissions (1855). In the winter of 1859-35 he made a tour in Egypt and the Holy Land, the result of which was his well-known volume on Simila and Plestine (1856). In 1857 he travelled in Russia, and collected much material for this Lectures on the Eastern Church (1867).

At the close of 1856 Stanley was appointed regius professor of Bennett. He went to Crete and Specclesiastical history at Oxford, a post which, with the attached Paris by Mr. Gordon Bennett, Jr.

canomy at Christ Church, he held till 1865. He published the first two volumes of ha History of the Jewsh Church in 1865 and 1865. In the storm which followed the publication of Essays and 1865. In the storm which followed the publication of Essays and Revuess Stanley opposed the High Church Party. In 1836 he published a Letter to the Bishop of London, advocating a relaxation of the terms of clerical subscription to the Thrity-nne Articles and the Prayer Book. An act amending the Act, of Uniformity, and carrying out in some degree Stanley's proposals, was passed in the year 1865. In 1862, Stanley accompanied the prince of Wales in Egypt and Palestine

In 1863 he was appointed dean of Westminster In December he married Lady Augusta Bruce, sister of Lord Elgin, then governor-general of India He wrote a third volume of his History of the Jewish Church, a volume on the Church of Scotland, another of Addresses and Sermons preached in America, and another on Christian Institutions (1881) He was constantly fighting for the interests of the poor He gave offence by defending Bishop Colenso, although he disapproved of Colenso's views, and, still more, by his invitation to the Holy Communion of all the revisers of the translation of the Bible, including a Unitarian among other Nonconformists He desired that the Athanasian Creed be optional instead of imperative in the Church of England In 1874 Stanley, who was much esteemed by Queen Victoria, conducted the Anglican ceremony at the marriage of the duke of Edinburgh and the grand duchess Marie He died on July 18, 1881, and was buried in Henry VII 's chapel

Stanley's other works include: Life of Dr. Arnold (1844), Essays on Chinch and State (1870); Memorials of Westmunster Abbey (1865). See G. G. Bradley Recollections of A. P. Stanley (1883); R. E. Prothero and G. G. Bradley, Life and Correspondence of Dean Stanley (2 vols., 1893).

STANLEY, SIR HENRY MORTON (1841-1904), Brit-ish explorer of Africa, discoverer of the course of the Congo, was born at Denbigh, Wales, on June 10, 1841, of a family named Rowlands or Rollant John Rowlands, by which name Stanley was baptized, was brought up first by his maternal grandfather. and after his death was boarded out by his mother's brothers at half a crown a week. In 1847 he was taken to the St Asaph Union workhouse, where the schoolmaster, James Francis (who eventually died in a madhouse), was a tyrant of the Squeers type, and in May 1856, Rowlands, after giving Francis a thrashing. ran away from school. His paternal grandfather having refused to help him, he became a pupil teacher at Brynford, where his cousin was master But within a year he was sent to Liverpool, where he lived in poverty with an uncle, and after working at various trades, he sailed as a cabin boy to New Orleans, where he landed in 1859. There he obtained a situation through the good offices of Henry Morton Stanley, who subsequently adopted the lad as his son, but died without making provision for him

When the Civil War broke out in 1867 Stanley enlisted in the Confederate army; he was captured at the battle of Shioh (April 1862), and after two months' impuisonment at Camp Dougha, Chicago, he obtained release by enrolling in the Federal artilery. In less than a month he was discharged as unfit. In Nowmber 1866 he returned to Liverpool "every poor, in bad hattle and in shabby clothes," and made his way to Denbigh, but was turned away from his mether's door. For a livelihood he took to the sea—was wecked off Barcelona—and in August 1864 enlisted in the United States anay. After the war he crossed the plans to Salt Lake City, Denver, and other parts, and became a vivid descriptive writer.

Thus began a series of adventures in search of "copy," which led him through Asia Minor, Tiffis and Tibet In 1866 Stanley revisited Denbigh and St. Asaph, returning thence to America, where he joined General Hancock's expection against the Red Indians, acting as correspondent for the Missouri Democrat and other papers His reports induced the New Pork Herald to send him to accompany the British expection of 1867-68 against the emperor Theodore of Abyssinā. Succeeding in sending through the first news of the fall of Magdala, Stanley received a roving commission from the proprietor of the Herald, James Gordon Bemett. He went to Crete and Spain, but in 1869 was recalled to. Paris by Mr. Gordon Bemett.

Convinced that David Livingstone was alive Bennett commissioned Stanley to go in search of him But he cumbered Stanlev with a large number of commissions in Egypt, Syria and Persia before the quest for Livingstone could be begun. Eventually he sailed from Bombay for Africa, reaching Zanzibar on Jan 6, 1871

The journey to the interior was begun on March 21, on Nov. to, having overcome innumerable difficulties. Stanley arrived at Uill, where he found Livingstone With Livingstone Stanley navigated the northern shores of Tanganyika, settled the question as to whether the Rusizi was an effluent or an affluent-a point then much debated in connection with the hydrography of the Nile basin, and regained Zanzibar on May 7, 1872 His story, made public in a picturesque narrative, How I Found Livingstone (1872), was received in London with some incredulity; but the journals of Livingstone, which he brought home, silenced the critics, and from Queen Victoria Stanley received a gold snuff-box set with brilliants and her thanks for his services

A series of public lectures in England and America followed In 1873, as war correspondent of the Herald, he accompanied Wolseley's expedition to Ashanti, which he described, together with his Abyssinian experiences, in a volume entitled Coomassie and Magdala · Two British Campaigns (London, 1874) On reaching the island of St Vincent from Ashanti in 1874 he first heard

that Livingstone was dead

Second African Journey .- Stanley now desired to return to Africa to determine geographical problems left unsolved by the deaths of Livingstone and Speke, and the discovery by Sir Samuel Baker of Albert Nyanza, a lake then reputed to extend illimitably in a southerly direction. A fund was raised by Lord Burnham, Gordon Bennett and others for an Anglo-American expedition under Stanley's command This expedition lasted from October 1874 to August 1877 and accomplished more than any other single exploring expedition in Africa. Politically the journey led to the foundation of the Congo State and to the partition of the hitherto unappropriated regions of Africa between the states of western Europe Stanley started from the east coast and reached the ocean again at the mouth of the Congo, having demonstrated the identity of that river with Livingstone's Lualaba by navigating its course from Nyangwe-the point at which both Livingstone and Lovett Cameron had turned aside

Of the three white men who accompanied him all died during the journey; Stanley himself was prematurely aged The discovery of the course of the Congo, though the greatest, was but one of many geographical problems solved during this memorable expedition The part played by the Kagera in the Nile system, the unity and approximate area of Victoria Nyanza, the true length and area of Tanganyika and the whereabouts of its outlet. and the discovery of a new lake, Dweru, which at the time Stanley believed to be a branch of Albert Nyanza, are some of the other discoveries made by Stanley at this time. The story of the expedition was given at length in Through the Dark Continent (London, 1878). Stanley's letters from Uganda and his call for missionaries to go to the court of Mtesa met with an immediate response and proved the first step in bringing the region of the Nile sources under the protection of Great Britain. Commercially the discovery of a navigable waterway penetrating the heart of Africa, was of paramount importance, a fact which was grasped by Leopold II, king of the Belgians, who sent commissioners to intercept Stanley at Marseilles, when he was on his way back to England, with proposals to return to the Congo, proposals which Stanley, much needing rest, put aside for the time. In November, 1878, Stanley went to Brussels and entered into the schemes of the Belgian king.

Congo Free State.-A Comité d'études du Haut Congo was formed and Stanley was entrusted with the leadership of the new expedition. Stanley reached the Congo in August 1879, and the work he accomplished there in the ensuing five years enabled the comité, which had meantime changed its name to that of Association internationale du Congo, to obtain the recognition of America and Europe to its transformation into an independent

Leopold. Stanley described his labours in The Congo and the Founding of its Free State (London, 1885). For the political aspects of the question see Africa. Partition Among European Powers: Congo Free State He was restricted by the enterprise of the French traveller de Brazza, who, reaching Stanley Pool by a more northern route, placed the neighbouring districts on the north bank of the Congo under French protection (1880). Stanley returned to Europe in the middle of 1884 and attended the Berlin Conference of 1884-1885, which dealt with African affairs, acting as technical adviser of the American plenipotentiaries.

Third African Journey .- Stanley now became interested in the schemes of Mr (afterwards Sir) William Mackinnon for establishing a British protectorate in East Equatorial Africa, and it was believed that this object could be furthered at the same time that rehef was afforded to Emin Pasha (qv), governor of the Equatorial Province of Egypt, who had been isolated by the Mahdist rising of 1881-1885 Stanley agreed to conduct an expedition, nominally in the service of the khedive of Egypt, for the relief of Emin. He decided to go by way of Zanzibar and the Congo State. He left Europe in January 1887 and at Zanzibar entered into an agreement with Tippoo Tib, the chief of the Congo Arabs, appointing him governor of Stanley Falls station on behalf of the Congo State, and making another arrangement with him to supply carriers for the expedition On June 15, Yambuya, on the lower Aruwimi, was reached, and here Stanley left his rearguard under command of Major E. M. Barttelot and Mr. J. S. Jameson On the 28th Stanley and the advance-guard started for Albert Nyanza, "and until Dec 5, for 160 days, we marched through the forest, bush and jungle, without ever having seen a bit of greensward of the size of a cottage chamber floor. Nothing but miles and miles, endless miles of forest." Starvation; fever. the hostility of the tribes, were daily incidents of this terrible march, during which Stanley lost nearly 50% of his men. On Dec 13, Albert Nyanza was reached, and after some delay communication was opened with Emin, who came up the lake from the Nile in a steamer. Disquieted by the non-arrival of his rearguard, Stanley retraced his steps, and on Aug. 17, 1888, a short distance above Yambuya, found that Tippoo Tib had broken faith, that Barttelot had been murdered, that Jameson (who soon afterwards died of fever) was absent at Stanley Falls, and that only one European, William Bonny, was left in the camp

Collecting those who survived of the rearguard Stanley for the third time traversed the primeval forest, and in January 1889 all that was left of the expedition was assembled at Albert Nyanza Of 646 men with whom he entered the Congo, but 246 remained In April the return journey to Zanzıbar by way of Uganda was begun. Emin reluctantly accompanying Stanley On this homeward journey Stanley discovered Ruwenzori (the Mountains of the Moon), traced the course of the Semliki River, discovered Albert Edward Nyanza and the great south-western gulf of Victoria Nyanza. During his stay in the Congo forests he had also obtained much information concerning the pygmy tribes As to the political results of the expedition. Stanley's proposals to Emin to hold the Equatorial Province for the Congo State or to move nearer Victoria Nyanza and enter the service of Mackinnon's British East Africa Company had not been accepted, but he concluded agreements with various chiefs in the lake regions in favour of Great Britain, agreements which were handed over to the East Africa Company Zanzibar was reached on Dec. 6, 1889, and the expedition was at an end. In Darkest Africa, was published (in six languages) in 1890.

Returning to England, Stanley was received with much honour, and received many distinctions. There was, nevertheless, bitter controversy over the fate of the rearguard of the expedition. On July 12, 1890, he married Miss Dorothy Tennant, second daughter of Mr Charles Tennant, sometime M P. for St. Albans. Later in the year he visited the United States, and in 1891-1892 went to Australia and New Zealand on lecturing tours. On his return he was renaturalized as a British subject, and after an unsuccessful attempt in 1892, he was elected member of parliament in 1895 He did not seek re-election in 1900 In 1895 Stanley pubstate ("The Congo Free State") under the sovereignty of King lished My Early Travels and Adventures in America and Asia, in which he retold the story of his experiences with the Red Indians and of he eastern pourney of 1860-1870. In 1897 Stanley paid his last visit to Africa. He went to the Cape as the guest of the British South Africa Company, spoke at the opening of the rail-way from the Cape to Bulawayo, vasted the Victora Falls of the Zambeza and had an interview with President Kruger, of whom he gives a characteristic pen-picture. One result of this journey was Through South Africa (1898), the last of his published works. In 1899 in recognition of his services in Africa he was made a KC B. The last, few years of his hie were spent mainly in retirement on a small evate he had purchased, Fuzehmond Terrace, Whitchall, on May 10, 1904, and was buried at Pibright. The monoith over his grave bears the inscription "Henry Morton Stanley 1841—1904" with his African name "Bula Mataru" and the one word "Africa".

In geographical discoveries Stanley accomplished more than any other explorer of Artica. Notwithstanding his frequent conflicts with Arabs and negroes, he possessed in extraordinary degree the power of managing native races, he was absolutely fearless and ever leady to startine either himself or others to achieve his object. His books differ widely from the ordinary books of travel. Stanley had a gift of dramatic narrative, and his power of portraiture was remarkable. Curnously, the least successful of his works was the only one which he cast in the form of fiction, My Kalniu, Prince, King and Slave. My Dark Companions and their Strange Stories (1893) is a valuable contribution to folklore.

Stronge Stories (1893) is a valuable contribution to loutoure.

The Authorisemph of Sir Henry Morton Stanley, ed by his wife,
Duochy Stanley, appeared in 1909 Henry M. Stenley, the Story of the
Life. . . (London, in d. 1871), by C. Rowlands, centains, not-the
standing many maccuraces, valuable information concerning his family
and early career The following books may also be consulted Mis

in Central Africa (1997).

STANLEY, THOMAS (1625-1678), English poet and philosopher, son of Sir Thomas Stanley of Cumberlow, in Herts, was born in 1625 His mother, Mary Hammond, was the cousin of Richard Lovelace, and Stanley was educated in company with the son of Edward Fairfax, the translator of Tasso He studied both at Cambridge and Oxford, and travelled widely in Europe. Stanley was the friend and companion, and at need the helper, of many poets, and was himself both a writer and a translator of verse. His Poems appeared in 1647; his Europa, Cupid Crucified, Venus Vigils, in 1649; his Aurora and the Prince, from the Spanish of J Perez de Montalvan, in 1647; Oronta, the Cyprian Virgin, from the Italian of G. Preti (1650); and Anacreon; Bion; Moschus; Kisses by Secundus . . . a volume of translations, in 1651. Stanley's most serious work in life, however, was his History of Philosophy (3 vols., 1655-61). A fourth volume (1662), bearing the title of History of Chaldaick Philosophy, was translated into Latin by J. Le Clerc (Amsterdam, 1690). The three earlier volumes were published in an enlarged Latin version by Godfrey Olearius (Leipzig, 1711). In 1664 Stanley published in folio a monumental edition of the text of Aeschylus He died at his lodgings in Suffolk Street, Strand, London, on April 12, 1678.

The English metaphysical school closes with Stanley, who went on weaving his faintastic conceits in elaborately artificial measures far into the days of Dryden and Butler. His History of Philosophy was long the principal authority on the progress of thought in

Stanley's original poems were imperfectly reprinted in Sir S. Egerton Brydges's edition of 150 copies in 1814. His "Anacreon" was issued, with the Greek text, by Mr. Bullen in 1892.

STANLEY, WENDELL MEREDITH (1904—), U.S. biochemist and Nobel prize winner, was brom on Aug., 16, 1904. In Ridgeville, Ind. After receiving his Ph.D. degree from the University of Illinois, Urbana, in 1290, he became a research associate and instructor in chemistry there. In 1931 he entered the Rockefeller Instituté for Medical Research, and in 1794 became a member of the institute. In 1938 he became director of the laboratory for vivus research at the University of California. In

research on the virus which caused the "mosaic disease" in tobaccoplants, Stanley found that while it appeared to act like an inammate chemical it presented evidence of being a living and growing organism. For "their preparation of enzymes and virus proteins in a pure form," Stanley and John H. Northrop divided equally one-half of the Nobel prize in chemistry in 1946, the other half being awarded to James B. Sumner for his discovery "that enzymes can be crystallized"

STANNARIES, un mines (late Lat. stannum, Cornish, stéan, tin) Stannary courts exercised a jurisdiction peculiar to Comwall and Devon. By ancient charters, the tinners of Cornwall were evempt from all other jurisdiction than that of the stannary courts, except in cases affecting land, the and limb. Tin mining in Cornwall, from the very earliest times was always prosecuted in accordance with a particular code of customs, the earliest charter which embodies them is that of Edmund, earl of Conwall, but it is minossible to say how far these customs co hack

Twenty-four stannators were returned for the whole of Cornwall. Their meeting was termed a parliament, and when they assembled they chose a speaker. In earlier times the combined tinners of Devon and Cornwall assembled on Hingston down, a tract of highland on the Cornish side of the Tamar After the charter of Earl Edmund, the Cornish stannators met (apparently) at Truro, those of Devon at Crockern Tor on Dartmoor An officer was appointed by the duke of Cornwall or the crown, who was lord warden of the stannaries. The last Cornish stannary parliament was held at Truro in 1752. A committee was appointed to report on the subject, and an act of parhament was passed (1836), suppressing the law courts of the stewards of the different stannaries and giving to the vice-warden their jurisdiction. By the Stannaries act, 1855, the respective parliaments or stannaries courts of Cornwall and Devon were consolidated By the Stannaries Courts Abolition act, 1806, the jurisdiction was transferred to the county courts. The most important customs were (a) "free tinners" had the right to work upon rendering the "toll-tin, usually one-fifteenth of the produce, to the owner or lord of the soil; (b) the right of "tin-bounding," that is, the right of bounding waste lands, subject to tin-toll

See G R Lewis, The Stannaries (1908); W. S. Lewis, West of England Tin Mining, with bibliography (Exeter, 1923); A. K. Hamilton Jenkin, The Cornish Miner (1927).

STANTHORPE, a town in the S.E. of Queensland, Australia, 198 mn. SW of Brisbane by rail Alltitude 2,650 ft; average annual temperature is 80° ft. 035° ft. 103° sverage annual rainfall is 305 in. It so no the main interstate line Brisbane-Sydney), and is a summer resort. It hes at the north end of one of the largest masses of granite in eastern Australia, and gold and comperary when fuerthy. Pon (1042) 2,380

and gold and copper are mined nearby. Pop (1947) 2,380. STANTON, EDWIN McMASTERS (1814-1869), American statesman, was born at Steubenville, O, on Dec 19, 1814. He attended Kenyon college at Gambier, O, and was admitted to the bar in 1836 In 1847 he removed to Pittsburgh, Pa As counsel for the State, he invoked successfully the aid of the Federal Government in preventing the construction of a bridge over the Ohio river at Wheeling, Va., (now West Virginia)-on the ground that the structure would interfere with the navigation of that stream by citizens of Pennsylvania He removed to Washington in 1856 In 1858 he was sent to California by the United States attorney general as special Federal agent for the settlement of land claims. Before the Civil War, Stanton was a Democrat, opposed to slavery, but a firm defender of the constitutional rights of the slaveholders, and was a bitter opponent of Lincoln, whose party he then hated and distrusted. In the reorganization of President Buchanan's cabinet in 1860 Stanton became attorney general, and he did what he could to strengthen the weak policy of the President Although he had often violently denounced President Lincoln, the latter thought he saw in Stanton a good war minister, and in January, 1862, invited him into his cabinet. Stanton was often harsh, and his peremptory manner was the cause of friction with the generals, an instance being his controversy with Gen. Sherman over the terms of surrender granted to J. E. Johnston's army. But he removed a horde of fraudulent contractors, kept the armies in the field well equipped hexameters and infused energy into procrastinating generals. Not the least of his achievements was the peaceable disbandment of 800,000 soldiers at the end of the war

Remaining in the cabinet of President Andrew Johnson, Stanton exerted all his energies toward thwarting the policies of that executive, especially those related to the reconstruction of the Southern States He expressed disapproval of the Tenure of Office Act, making the consent of the Senate necessary for the removal of civil officers, and diafted the supplementary act on reconstruction, passed over the President's veto on July 19, 1867. Stanton was finally asked to resign, and on his refusal to do so the President suspended him (Aug 12) from office and appointed Gen. Grant (who had disapproved of the secretary's removal) secretary ad interim When the Senate, however, under the terms of the Tenure of Office Act, refused (Jan 13, 1868) to concur in the suspension. Grant left the office and Stanton returned to his duties On Feb. 21, 1868, Johnson appointed Gen Lorenzo Thomas secretary of war ad interim, and ordered Stanton to vacate, but on the same day the Senate upheld Stanton, and by way of reply the secretary made oath to a complaint against Thomas for violating the Tenure of Office Act, and invoked military protection from Gen Grant, while Congress came to Stanton's rescue by impeaching the President, the principal article of impeachment being that based on the removal of Stanton (see JOHNSON, ANDREW). When the impeachment proceedings failed (May 26) Stanton resigned and returned to the practice of law. Stanton had a violent temper and a sharp tongue, but he was courageous, energetic, thoroughly honest and a genuine patriot He died in Washington on Dec 24, 1869

STANTON, ELIZABETH CADY (1815-1902), American leader in the woman's rights movement, was born in Johnstown, NY, on Nov. 12, 1815, the daughter of Judge Daniel Cady. In her father's law office she learned of the discriminating laws under which women lived, and many tragic cases observed there determined her in the ambition to equalize the rights of her sex. She did much by the circulation of petitions to secure the passage in New York in 1848 of a law giving a married woman property rights In the same year, on June 19 and 20, in Seneca Falls, was held, chiefly under the leadership of Mrs Stanton and Mrs. Lucretia Mott, the first woman's rights convention in the United States. For this convention Mrs. Stanton had drawn up her famous woman's bill of rights setting forth the inferior and unjust position of women in State, church, law and society, and resolutions demanding redress, which were adopted. All of these demands have since been extensively granted One of them, introduced without Mrs Mott's approval, was a resolution in favour of equal suffrage for women, which, when approved, became the first organized demand in the United States by women for the ballot, In 1850 she became associated with Susan B. Anthony and for 40 years the two worked together, each admirably supplementing the other, Mrs Stanton writing, Miss Anthony managing affairs. In 1867-70 they co-operated in editing The Revolution, a women's rights newspaper She was president of the National Woman Suffrage Association from 1865 to 1893. With Miss Anthony and Mathilda Gage she wrote The History of Woman Sufrage (4 vol. 1887-1002) She died in New York city on Oct. 2, 1902. See T. Stanton and H S Blatch, ed., Elizabeth Cady Stanton as Revealed in Her Letters, Diary and Reminiscences (1922).

STANYHURST, RICHARD (1547-1618), English translator of Virgil, was born in Dublin in 1547. At University College, Oxford, he met Edmund Campion. After studying law, he went to Spain, ostensibly as a physician, but really to keep Philip II. in touch with the Catholic interest in England. In 1602 he took holy orders, and died at Brussels in 1618. He translated The Pirst Foure Bookes of Virgil his Aeneis (Leiden, 1582), to prove Gabriel Harvey's theory that classical prosody could be applied to English poetry. The translation is a jargon arranged in so-called

A reprint in 1583 by Henry Bynneman forms the basis of J Maid-ment's edition (Edinburgh, 1836), and of Professor E Arber's reprint (1880), which contains an excellent introduction Stanyhurst's Latin voiks include De rebus in Hibernia gestis (Antweip, 1584) and a life of St Patrick (1587).

STAPLE, originally a prop or support, in current usage a Ushaped piece of metal, generally galvanized or wrought iron, in wire form with sharpened points, and used as a fastener by driving into wood, also the chief or ordinary bulk articles of trade In England the term was applied to towns which were appointed by the king to be the merchants of the staple. These merchants had a monopoly in the staple commodities, viz, wool, wool fells, leather tin and lead, and were the our of all English trading companies. (See also Natl Manufacture )

See C. Gross, Gild Merchanis, W Cunningham, Growth of English Industry and Commerce

STAR, the general term for the luminous bodies seen in the sky, but more especially applied to the "fixed stars," which maintain practically the same relative positions in the sky and form constant patterns or constellations. The planets or "wandering stars" are accordingly excluded (see Astronomy)

Unlike the planets which shine by reflected light from the sun, the stars are self-luminous. They are bodies of the same nature as the sun; and the only reason why the sun appears so much more brilliant is that it is comparatively close to us. The following figures speak for themselves . Distance of sun-93,000,000 miles; distance of nearest star-25,500,000,000,000 miles. Each star is a fiery globe and most stars are enormously larger than the earth. though a small proportion are comparable in size with the major planets. Some stars may have planets, but it is not possible to detect these by direct observation; if sufficiently massive, they might be detected by the disturbance of the motion of the parent star caused by their gravitational attraction. In this way a few of the nearer stars have been proved to have companions which, though considerably more massive than Jupiter, are much less massive than any known star. It can be inferred that these companions are not self-lummous, and they are therefore to be regarded as planets.

Although we have been able to learn indirectly the actual dimensions of many of the stars, their size is not revealed by telescopic observation. In the largest telescope a star remains a point of light, and there is no possibility of observing surface markings such as we see on the sun. One unexpected feature, however, is seen directly a telescope is used, a considerable number of the stars which appear single to the naked eye, are seen in the telescope to consist of two stars. The occurrence of close pairs of stars is far too frequent to be due to chance; and, indeed, in some cases the two components have been observed to be revolving round one another. We have to recognize that although single stars like the sun are in the majority, evolution has very frequently taken another course and furnished pairs of luminous globes.

It can be recognized with the naked eye that the stars differ in colour. The colour is not very vivid; but, for example, if the reader is familiar with the constellation Orion, he will easily see that the brighter of the two shoulder stars (Betelgeuse) has a reddish tinge in contrast to all the other bright stars in the constellation, which are white. The quality of the light (crudely indicated by the colour, and in a more detailed way by examination with a spectroscope) is a clue to the surface temperature of the star. As we should expect, the "white-hot" stars are the hottest, and the "red-hot" stars the coolest. Another fact which can be verified with the naked eye, though it requires patient and systematic watching, is that some of the stars give an inconstant light There are several different kinds of variable stars described below: in one class the variation is a genuine physical change, the star swelling and contracting with regular pulsations.

The Stellar Universe .- Thus the statement that the stars are "suns," while giving a correct general idea of their nature, must be amplified to cover a wide variety of objects with many individual characters. They differ greatly in physical condition. Betelgeuse (above-mentioned) is an example of one extreme; it is a gigantic globe so large that the whole orbit of the earth could be put inside it, but so tenuous that its density is less than 1000 that of air-many a so-called vacuum is not more exhausted ian this. An example of the other extreme is the companion of Sirius (see Sirius), which is compressed to a density far exceeding anything known on earth, and is in size not so large as the planet Uranus. Besides the study of the stars as individual units we have to consider their organization as a system. The principal indication of this organization is found in their motions. Although we often call them fixed stars, they are moving rapidly with speeds of the order 10 to 100 mi a second. Notwithstanding their great distance, the resulting changes of position in the sky can be determined by refined measurement, it is the exception for a bright star to have a motion too small to be detected in, say, 20 years. Further evidence of organization is afforded by the distribution of the stars in the sky. They are crowded toward one special plane, viz, that marked out by the Milky Way, or Galaxy, a hand of diffuse light stretching all round the sky which, under telescopic examination, is resolved into millions of faint stars. In general, in speaking of the stars we refer to this galactic system or universe, but it is known that the spiral nebulae, of which there are a great number, are island universes coequal with our galactic system. In some of these other galaxies individual stars can be detected by aid of the largest telescopes.

We find ourselves then in a galaxy which is just one amid many millions This galaxy has two dwarfish satellites-the Star Clouds of Magellan, which are at a distance of about 80,000 light-years Beyond these, the nearest of the other systems is so remote that light takes 750,000 years to traverse the void which separates us from it The number of stars in our own galaxy is of the order of 100,000 millions. To one of the less distinguished stars of this host is attached the earth, which is our home. The evolutionary process which has swept across this system, condensing stars out of the numitive mist, has occurred a time which must be reckoned in thousands of millions of years. From this orgy of inconceivable numbers we may, perhaps, glean an impression of man's place in the material universe. The space and the time which belong to him are as nothing in the far extent and the untold ages of inorganic nature. Is terrestrial man the one and final purpose of it all? Nothing in astronomy has appealed more to the imagination than the conception that each of the myriad points of light in the sky may be giving warmth and light to planets like our earth. It would seem a presumption to deny to them inhabitants of the same order of creation as ourselves. Nevertheless, we must not forget the prodigality of nature. If indeed she has no grander aim than to bring forth her favoured child, man, it would be just like her methods to scatter a million stars whereof but two or three might haply achieve her purpose. Strong reasons have been given by J. H. Jeans for regarding our solar system as a very unusual development. Although probably not unique, the formation of a system of planets is not the normal course of evolution of a star. It only happens when, at a critical stage of development, disruption is caused by the accidental approach of another star-a fortune which, perhaps, not one star in a hundred millions would be likely to undergo. This theory is subject to much uncertainty; but it is at least a useful corrective to the view, often too facilely accepted, which assumes an almost infinite plurality of hving worlds.

History of the Study of Stars.—In the older books on astronomy most of the space is devoted to the bodies of the solar system (sun, moon, planets, comets); the little that was known of the stars could be compressed into two or three chapters at the end. It is natural that our first acquired knowledge should relate chiefly to the bodies that are nearest to us. Much labour was devoted to observing the stars, but that was largely because they had to serve as graduation marks in the sky against which the movements of the planets and comets could be recorded. Of late the centrifugal march of astronomical knowledge has been very remarkable, and the study of the stars is now the largest field of astronomical research. The following may be selected as the chief fandmarks in this progress:

 The first new star or nova was discovered by Tycho Brahe in 1572. 2 The first variable star (Mita Cett) was discovered by Fabricius in 1596.

3. The first double star (Mizar) was discovered by Jean Baptiste Riccioli in 1650

4 Edmund Halley first detected the proper motions of stars (Arcturus, Aldebaran, Sirius) in 1718

5 Sit William Herschel may be tegarded as the pioneer of studies of the sidered system He discovered the solar motion (motion of the sun through the system of the stars) in 1783. By his famous counts of stars (start-gauges) he established the fialtened form of the stellar universe. In 1803 he was able to announce, from his measures of double stars made drung the previous 25 years, the confirmation of the theory (urged by Christian Mayer in 1720) that the components revolve round one another

6 In 1839 distances of the three stats 61 Cygni, α Centauri and Vega were found by measurement of parallax by F W Bessel, T Henderson and F G. W. Struve respectively. This gave the

first definite idea of the scale of the stellar system

7 In 1862 William Huggins applied the spectroscope to the stars and identified many familiar terrestrial elements as present in their atmospheres. The classification of stars according to their spectra was instituted by Angelo Secchi shortly afterwards.

8 Photography of the stars was developed between 1882 and 1887, the international photographic chart of the heavens and catalogue (not yet completed) being planned in the latter year

9 Measurement of the velocities of stars in the line of sight by means of the spectroscope was developed very slowly in the latter part of the 19th century. The early measurements were entirely untrustworthy, and it is difficult to say when this powerful and to stellar research properly started. Good results were obtained by H C Vogel and J Schemer in 1838–91. A great development of this branch of work was brought about by W W Campbell from 1897 onward. The first spectroscopic binary star (Mizar) was tough by E C Pickening in 1880.

10. J C Kapteyn discovered, in 1904, that, at least in our local system, the stars are moving in two main streams. This gave great stimulation to statistical studies of the sidereal universe.

11. The distinction between giant and dwarf stars made manifest by the researches of E. Hertzsprung and H. N. Russell began to be generally accepted about 1913

12. The study of the internal constitution of the stars, on the basis of the theory of radiative equilibrium, was begun by A S Eddington in 1916.

13 The first direct determination of the angular diameter of a star, ic, the apparent size of its disk, was made by F G Pease and J A. Anderson in 1920, using an interferometer designed by A. A. Michelson.

14. The physical theory of ionization was applied by M N Saha to the interpretation of spectral features of the stars in 1920 This led to a branch of research which has had most extensive developments.

The Twinkling of Stars .- Before entering on a fuller account of this progress we must refer to a question which is often put Why do the stars twinkle? If we trace the beam of light, roughly 10 in. in diameter, which fills the eye-pupil back toward the star, it has passed through some miles of terrestrial atmosphere. Differences of density due to slight inequalities of temperature will cause continual changes of retraction at one point or another on the path, giving rise to a general unsteadiness. More important still is the "interference of light." The irregularity of density may be such that the light at opposite edges of the narrow beam has traversed different effective thicknesses of air, so that the corresponding waves are delayed by different amounts. If the delay amounts to half a wave length the waves will arrive creston-trough, and, instead of summing up to give a bright starimage, they will cancel one another. Thus the image pops in and out as the changes of atmospheric density succeed one another The condition for cancelling is different for light of different colours (corresponding to different wave lengths), consequently the star sparkles with different colours. To understand why this does not happen to the light of the planets we must recall that the disk of the planet, unlike the star-disk, subtends a considerable angle at the eye. The diameter of Saturn, for example, is normally about 20 seconds of arc, which means that at the height of a mile the rays which reach the eye fill an area 6 m. in diameter. This gives plenty of scope for the variations of the individual beams ('A'm in diameter) to average out, and consequently they combine to give a fairly steady brightness. Interference or canceling of waves occurs between waves teaching different parts of the pupil, but not between waves starting from different parts of the disk of the planet or star, thus trivialing depends on the ratio between the angular sizes of the celestial object and of the eyepula as viewed from an average height in the earth's atmosphere

## NUMBER AND MAGNITUDE OF THE STARS

On a clear dark night the stars seem to be innumerable in multitude, but in reality the number in the whole sky visible to the unaided eye is about 6,000 A small telescope greatly multiplies the number, and the largest instruments (aided by long photographic exposures) would reveal some hundreds of millions. The brightness is expressed by "magnitudes," the progressively fainter stars being of progressively greater magnitude. A star is defined to be one magnitude higher than another if its light is fainter in the ratio 2 512; this ratio is adopted so that a difference of five magnitudes may correspond to a light-ratio of 1 100. The faintest stars visible to the naked eye on clear nights are about the 6th magnitude The brightest star, Sirius, has magnitude -1.6 se, 76 magnitudes brighter, or just over 1,000 times more luminous, than the faintest naked-eve stars. Classified on the same scale, the sun's magnitude is -26 7. It is possible with the largest instruments to reach stars of about the 21st magnitude. It gives some idea of the light-grasp which has been attained if we notice that the interval from the sun to Sirius (25 magnitudes) is comparable with the interval from Sirius to the faintest stars observed (23 magnitudes).

If the stars were distributed uniformly through infinite space and their light suffered no absorption, each magnitude would comprise 3.98 times as many stars as the preceding magnitude (the number 3.98 times as many stars as the preceding magnitude (the number 3.98 is the 3-power of the light-ratio 2.512). This theoretical star-ratio is not realized in the actual distribution. It may be taken as a rough rule that an increase of one magnitude multiplies the number of stars about threefold for the highest stars. This is an indication that the density of distribution of the stars in space falls of at great distances—that we are in the middle of a limited cluster or star-cloud. The following table gives the results of F H Seares and P, J, van Rhyin (1925) for the number of stars in the sky brighter than the midicated visual magnitude

Magm-	Number	Magni-	Number	Magni-	Number
tude	of stars	tude	of stars	tude	of stars
40. 5.0 6.0 70 8.0	530 1,620 4,850 14,300 41,000	90 100 11.0 . 120 130	117,000 324,000 870,000 2,270,000 5,700,000	14.0 15.0 16.0 17.0 18.0	13,800,000 32,000,000 71,000,000 150,000,000 296,000,000 560,000,000

Up to a certain point each magnitude contributes more star hight than the precoding, the mcressed number of stars in the magnitude-interval more than counterbalancing their individual faintness. The maximum is reached between the 11th and 12th magnitudes, the 1,500,000 stars in this interval giving a combined light equivalent to 8, stars of magnitude 10. Beyond this the contribution falls off. All the stars together give as much light as 1,100 stars of magnitude 1.0—a result which has been checked closely by direct measurement of the general light of the sky By extrapolating to fainter magnitudes, Seares and van Rhijn estimated the total number of stars to be about 30,000,000,000. In 1925 the dimining of distant stars by the diffuse matter in interstellar space was not realized. This dimming must result in counts of stars gwing an underestimate of the total number of the stars.

The above figures relate to the whole sky. Interesting results

are tound when we compare the density of distribution of the stars in different parts of the sky, particularly when we compare regions in the plane of the Milky Way with those near its poles. The galactic concentration (ratio of the number of stars in equal areas in the galactic plane and at the galactic pole) increases from 34:1 for mag 4 to 4 3.1 for mag. to, and to 2 1.1 for mag 18. These results refer to photographic magnitude, no sufficiently extensive counts for visual magnitude being available. The great access of stars in the galactic regions is not wholly or even mainly due to the star-clouds of the Milky Way itself; the star-density increases steadily from the poles to the galactic plane, and the conreached. This phenomenon was discovered by William Herschel and the modern results are in good agreement with the starcounts made by him and by his on, John Berschel.

The density of the stars in the vicinity of the sun (the "local system") was found by Jacobus Kapteyn to diminish in all directions outward from the sun They were therefore believed to form one of many star-clouds lying in the galactic plane, the whole being coiled into a spiral nebula. But the effect of dimming by obscuring matter has to be taken into account. The average effect is an obscuration of about 08 magnitudes in a distance of a kiloparsec The obscuring matter is not uniformly distributed and the amount of the obscuration is different in different directions and does not increase uniformly with distance. It is at present doubtful whether there is an increase or decrease of star-density outward from the sun and the existence of a local system remains uncertain From other considerations it is known that we are very far (about 8,000 parsecs or 26,000 light-years) from the centre of the galaxy, which is found to be in the direction of the constellation Sagittarius. The sun cannot be said to occupy a privileged position among the stars it is an outlier in the galaxy, which in turn is only one among many millions of its kind

Nomenclature of the Stars.—The brighter stars are designated by a Greek letter followed by the name of the constignation, according to a system introduced by J. Bayer in his star maps in 1605. The letters are assigned roughly in order of brightness, but for stars of nearly equal brightness the order is that of position in the constellation usually beginning at the head of the object figured. Alternatively, a system of numbers (followed by the constellation name) introduced by John Flamsteed can be employed; this covers many stars which have no Bayer letter. Flamsteed's numbers were assigned in order of right ascension. For example, 27 Germonium — 6 Geminorum, 32 Leonis « Leo-

nis = Regulus A number of ancient names of conspicuous stars reference to a theory of the progress of stellar evolution which survive, many of these are of Arabic origin. The list on page 319 gives those which are familiar to the modern astronomer, together with their Bayer equivalents and their visual magnitudes

The Arabic names of many additional stars are in common use in sea and air navigation, where a proper name is preferred to a Greek letter followed by the name of the constellation, the Arabic names of these additional stars are rarely used by astronomers Only 20 stars are ranked as brighter than mag 1 5 Of these 17 (including the variable Betelgeuse) are named in the above list. The other three are the southern stars, & Centauri (mag oo6),

β Centauri (0 86), β Crucis (1 50). Stars not bright enough to have a constellation letter or number are designated by their reference number in some catalogue Thus we have names like Bradley 1,940, Groombridge 2,230, Boss 3,932, the last reference (Lewis Boss, Preliminary General Catalogue), being especially preferred The most comprehensive source of reference is the Bonn Durchmusterung made by Argelander. This work, completed in 1862, lists the places of 324,000 stars between the north pole and 2° S. An extension to 23° S by Schonfeld adds 133,000 stars Star charts to be used with the catalogue are published, and there is no difficulty in identifying in the sky a star referred to, for example, as B D.+13°, 2,966. The Cordoba Durchmusterung (CDM) and Cape Photographic Durchmusterung (CPD,) fulfil a similar function for the rest of the southern sky. For stars fainter than the limits of these surveys an author must describe the identity as best he can.

Double stars are generally designated by the name of the discoverer, with the ordinal number of his discovery, or the number in Burnham's General Catalogue may be given. Variable stars are assigned (in order of discovery in the constellation) Roman capital letters from R to Z, or a pair of these letters, eg., X

Cygni, RT Aurigae Colour of Stars.—In stellar observation the photographic plate is used quite as commonly as the eye Alongside the visual scale of magnitudes measuring the brightness of the stars as judged by the eye, we have a photographic scale of magnitudes giving the brightness as judged by the effect on ordinary photographic plates It is well known that blue light has proportionately greater actinic power than red light; consequently a comparison of the magnitudes of a star on the two scales gives a measure of its colour The difference, photographic minus visual magnitude, is called the colour-index. (See Photography, Celestial) The visual estimation of magnitudes for stars differing in colour is complicated by the Purking effect, the relative sensitivity of the eve to differing colours varying with the intensity of the light Photovisual magnitudes, determined photographically with isochromatic plates and a suitable colour filter, agree closely with the visual scale and are free from the Purkinie effect, and have accordingly in large measure superseded the visual magnitudes.

A classification which runs nearly parallel with classification by colour is afforded by examination of the spectrum of the light In the Draper classification, now universally adopted, a continuous sequence of types is recognized denoted by the letters O, B, A, F, G, K, M. Intermediate types are indicated by decimal division, e.g., A2 is a type two-tenths of the way between Ao and Fo. A cursory examination of the spectrum is sufficient to determine the type, and 225,000 stars have been classified in this way by Miss A. J. Cannon (Harvard Annals, vols. 91-99). The sequence O to M corresponds to progression in colour from blue to red, and progression in temperature from the hottest to the coolest stars. The sun is of type Go. The percentages of stars catalogued in these classes are: B, 2; A, 29; F, 9; G, 21; K, 33; M, 6. Type O is rare, not more than 20 stars brighter than mag. 6.25 being known. The letters R, N, S denote other rare types whose relation to the recognized sequence is still uncertain. The properties of the stars (distribution, mass, luminosity, motion, variability, etc.) are all closely correlated to the spectral type; so that in nearly all investigations it is necessary to study the different types separately. The terms "early type" and "late type" are still commonly used in accordance with the order in this series, ie., for the bluer and redder stars respectively. The terms originally had is now entirely discarded

Some progress has been made with the direct measurement of the heat received from the stars, and the corresponding bolomet-11c magnitudes (related to heat intensity in the same way that visual magnitudes are related to light intensity) have been determined The star-image is focussed on a small disk in which a thermoelectric junction is embedded, and many hundreds of stars are found to give sufficient heat to be measured in this way. The main trouble in these investigations is that the radiant heat over a certain band of wave lengths is largely absorbed by the watervapour in our atmosphere, and rather large corrections must be applied on this account. The bolometric magnitude may also be applied of this account inferred from the visual magnitude by applying a correction depending on the spectral type of the star This correction, called the heat-index, is analogous to the colour-index, and varies in correspondence with it. Naturally, the red stars are "brighter" bolometrically than visually, because their radiation is of low luminous efficiency The greatest luminous efficiency is for stars of types F and G, perhaps because the human eye has been developed so as to make the most of sunlight. In still hotter stars there is a falling off of luminous efficiency, the radiation being too far in the violet and ultra-violet to suit the eye

Absolute Magnitude.-We turn now to consider the real brightness of the stars How would they compare with the sun in splendour if we could see them at the same distance? To infer the true brightness from the apparent brightness we must first know the distance (for the methods of measuring the distance see Parallax). An idea of the variety of brightness may be given by considering the seven most conspicuous stars. Sirius gives 28 times the sun's light, but it has a companion only 3 40 as bright as the sun. Canopus is so remote that its distance cannot be found accurately, but it can scarcely be less than 10,000 times as luminous as the sun. a Centauri consists of two stars, one almost a replica of the sun and the other considerably fainter. Then follow Vega and Arcturus with luminosities 50 and 100 in terms of the sun. Capella consists of two stars, with luminosities 110 and 70, having a faint distant companion of luminosity about oor. Rigel is remote, but its distance is more certain than that of

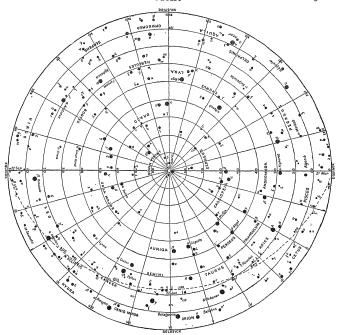

Canopus, its luminosity is greater than 10,000.

This shows that there are stars tar surpassing the sun in brilliancy; but, naturally, if we pay attention only to the most conspicuous stars we shall form an exaggerated idea of the general order of brilliance. There would be the same difficulty if we extended our survey to all the naked-eye stars; these would include the most luminous stars contained in a very wide region and the feebler stars in a much smaller region. It is only by rather elaborate investigations that we can get together a fair sample of the stellar population, in which the luminous stars are not over-represented by forcing themselves on our attention. According to the latest discussions the following table gives the relative proportions of stars of different degrees of intrinsic brightness in any volume of space:

Light power	Number	Light power	Number
10,000 × sun 1,000 " . 100 "	3,300 42,000	1 Xsun . 0.1 " 0.01 "	200,000 350,000 500,000 600,000

Stars fainter than the sun far outnumber those which are brighter. At present the faintest known star is one to which attention was drawn by G. van Biesbroeck. It is a distant companion to the star BD+4°4048 and has an absolute photovisual magnitude of 18.1 and an absolute photographic magnitude of 19.5 It has only 1/200,000 of the brightness of the sun, but it is still seven magnitudes brighter than Jupiter at full phase. It is intrinsically fainter by about three magnitudes than the next faintest known star, Wolf 359. The faintest known stars are all cool red stars.

At the other end of the scale it is difficult to assign an upper limit to the brightness because the objects suspected of great brilliancy are generally too remote for parallax measurement. In

the star clusters, however, we see a group of stars all at practically the same distance, and can therefore measure at once the relative hightness of different classes of objects. The variable star S Doradas in the Greater Magellaine Cloud has a mean absolute magnitude -9-4(500,000/\$um), and other stars in the same cloud are not far short of this. The tange in real brightness of the stars is at least 24 magnitudes—very much the same as the range in apparent brightness of are as it is possible to observe it.

Size of Stars.—The radius of a star may be calculated from the absolute luminosity (which requires a knowledge of the star's distance) and the observed surface-temperature. Other things being equal, the luminosity is proportional to the area of the surface, ie, to R2, but allowance must be made for the different radiating power of surfaces of different temperatures, this allowance can be calculated from the laws of radiation (Planck's law) In this way it is found that the stars differ greatly in size Some have diameters some hundreds of times greater than that of the sun; others have diameters less than one-hundredth that of the sun If the sun were placed at the centre of Antares. the entire orbit of Mars would be well within the star. Van Maanen's star, on the other hand, is smaller than the planet Neptune. For a few stars, the sizes deduced from the star's luminosity and surface temperature have been confined by direct measurement of the apparent angular diameter of the disk with Michelson's interferometer

Interferometer Measurements.-The measurement of the angular diameters of a few favourable stars has been made by means of Michelson's interferometer (q.v). As adapted to astronomical work this consisted of a 20 ft. beam carrying two inclined mirrors which could slide along it, and carried on the 100 in telescope at Mt. Wilson observatory; the light from the movable mirrors fell on two fixed mirrors, and was directed by them on to the great telescope mirror Virtually the observer was looking simultaneously through two apertures whose separation could be varied up to 20 ft, very much as in a gigantic range finder. (See BINOCULAR INSTRUMENT Stereoscope) The effect of using two apertures is that the spurious (diffraction) disk of the stellar image is crossed by fine diffraction lines, and the lines become closer as the separation of the apertures is increased. If the object looked at is not a mere point of light, its finite size blurs the diffraction pattern, and the object of using widely separated apertures is to obtain a diffraction pattern so fine that even the invisible disk of a star is sufficient to blur it out and make it disappear. Seven stars have been found to have angular diameters exceeding o."02 which is about the limit attainable with this instrument, a 50 ft interferometer has been constructed at Mt. Wilson, with which some further measures have been made, but the great majority must remain beyond the scope of this method. In some ways this application of the interferometer is to be regarded rather as a tour de force than an important advance of knowledge, serving merely to confirm the angular diameters inferred from the diameters, computed as described above, and measured distances Of special interest, however, are the observations of the variable stars, Mira Ceti and Betelgeuse; here the interferometer measurements indicate variations in the diameter, rare. and seem to confirm the theory, put forward on other grounds, that this type of variability is due to pulsation.

Another application of the interferometer is to measure the separation of double stars in which the components are so close that ordinary visual measurements are impossible. In particular Capella, which is, known to be a double by spectroscopic observation, cannot be resolved by any telescope. Nevertheless, by interferometer measurement the ordinary by the second of the second

## DOUBLE STARS

About the year 1650 Jean Baptiste Riccioli made the first discovery of a double star, viz., Mizar or § Ursae Majoris, the middle star in the tail of the Great Bear. Looking at Mizar with the naked eye, we see a fainter star, Alor, very close to it; it is a

fair test of eyesight to separate them. Their separation is however, 11', and although there is no doubt that Mizar and Alcor have a physical association, since they are found to be moving at just the same rate across the sky, the term double star is only applied in case of much closer proximity Riccioli's discovery was that Mizar itself consists of two stars separated by 15" or about 10 of the distance between Mizar and Alcor This would now be regarded as a wide pair, and many of the most interesting double stars have a separation under 1". The actual distance between the two components of Mizar is not less than II times the distance of Neptune from the sun. The two stars must be attracting one another, but the gravitational control across such a distance is so teeble that they will take more than 3,000 years to complete their orbital revolution. It is, therefore, not surprising that the measures made during the last 150 years fail to indicate definitely any orbital motion; and the only evidence of genuine connection (apart from the improbability of two independent bright stars lying so closely in the same line of sight) is aftorded by their common motion across the sky, and common radial velocity.

Similar discoveries followed rapidly  $\theta$  Orionis (in the mids of the great nebula) was resolved by Huyghens in 166.9. A misst by Hooke in 1664. In the southern hemisphere the duplicity of  $\alpha$  Crucis and  $\alpha$  Centauri was discovered by Jesut missionaries in 1685-89. The foundation of systematic measurement and study of double stars is due principally to William Herschel and Whilehm Struve The latter, working at Dorpat between 1813 and 1835, formed a catalogue of 3,110 pairs as the result of surveying about 120,000 stars.

The number of recognized visual double stars is now about co,000, but the number is necessarily somewhat arbitrary since, if too wide limits of separation are admitted, stars which are only in accidental poximity may be included. Among the naked-eye stars, one in nine is a telescopic double. It is certain that the true proportion of binary systems is much greater than this, many being too close to be resolved with the telescope. Thus, taking the nearest known stars (which give the best chance of observing duplicity), eight out of 20 are double.

Catalogues of double stars no doubt contain a number of spurious pairs, i.e., stars which are not actually near one another in space and merely happen to lie in the same line of sight, but considerations of ptobability show that there will not be many of these. The physical connection is generally shown, as in the case of Mizar, by common proper motion II spectroscopic determinations of radial velocity have been made these will provide an additional check. The connection implied is evidently the connection of a common origin. The two stars were born from the same abould, they originally shared in common the velocity of the parent hebula, and they have given the same influence to get their bear in most of them the gravitational tie is too weak to resust any differential disturbance, e.g., another star passing between the pair. The fact that so many of these wide doubles survive teaches us that chance approaches of stars to one another must be very rare.

Of greater interest are those double stars close enough together to show the effects of their mutual gravitation. There are about 170 double stars for which it has been possible to work out definite orbits. In about 2,000 more there is a rough indication of orbital motion, but the arc described since observation commenced is too short to determine the orbit satisfactorily. The shortest periods are 5.7 years (8 Equulei) and 6 9 years (13 Cet1); about 60 pairs have periods of under 100 years It is natural to enquire whether the planes of the orbits tend to he m any particular direction-parallel to the galactic plane, for example. A curious difficulty arises in this investigation. If the reader has watched the revolution of a cup-anemometer (or of a garden sprinkler) he will probably recall that the direction of revolution appears obvious and unmistakable, but after blinking the eyes the revolution seems just as unmistakably in the opposite direction and in a different plane. For the same reason we always find two planes of rotation of the double star, either of which may be the true one We can only adopt both planes, and investigate as best we can the resulting mass of data, half of which is correct and half spurious. So far as can be ascertained the planes of double star orbits are quite at random.

The two dog-stars, Sirius and Procyon, are double stars of exceptional historic interest. Being conspicuous stars they were well observed a hundred years ago and used as fundamental reference stars for determining time, etc. It was found that they were moving irregularly-not with uniform proper motion like other stars It was evident that each was being disturbed by the gravitation of a massive body in its neighbourhood, although the comand orbits were computed from the observations, the periods of revolution being 50 and 39 years respectively The disturbing stars, whose existence was thus convincingly demonstrated, have since been seen. The companion of Sirius was observed by Alvan Clarke in 1862, and 1s a comparatively easy object for modern telescopes; the companion of Procyon, which is more difficult, was observed by Schaeherle in 1806. They are faint stais, respectively 10 and 13 magnitudes fainter than their primaries Nevertheless, they must be massive bodies to exert so large a pull on their brilliant neighbours

Another star of special interest is the double star, 6: Cygn: In 1942 Stand found that one of the visual components was perturbed by an unseen faint companion, which proved to have a mass of only  $\frac{1}{2}$  that of the sun. This is considerably more massive than Jupiter, but much less massive than any star of known mass. It is inferred that this faint companion cannot be self-luminous and it must therefore be regarded as a massive planet and not as a star.

Masses of Stars.—The orbital motion of double stars conforms to the law of gravitation. It gives evidence that gravitation is universal in the stellar system. The study of binary systems performs a unique service in the general advance of our knowledge of the stars since it is through it that we arrive at knowledge of the stars. By the law of gravitation the extent to which a body disturbs the motion of other bodies is proportional to its mass. It is when we find bodies in dose proximity that we obtain a chance to observe the disturbance, and so obtain a measure of the mass. It is good fortune for the astronomer that the course of evolution has been such as to provide pairs of stars close enough together; otherwise we should probably still be in total ignorance as to the masses of stars, except in so far as the sun's known mass might be assumed to be twrated.

If  $M_1$ ,  $M_2$  are the masses of the two components, a the mean distance between them (strictly the semiaxis major of their relative orbit), and P the period of revolution, Kepler's laws give

$$k(M_1+M_2)=a^3/P^2$$

where k is a universal constant. Let us measure the mass in terms of the smis mass a unt, the perfol in years, and an astronomical units, sc, in terms of the earth's distance from the sun Applying the equation to the earth's motion round the sun (the earth's mass  $M_t$  being negligible) we see that for these units k=1. Now apply the equation to Sritus. The mean distance of the two components is 7.55 seconds of arc. To convert this into linear measure we must know the parallar of Sirus, 9.37 second. This ments that one astronomical unit seen at the distance of Sirius would appear to catend 0.37 second; hence 7.55 seconds corresponds to 9.4 astronomical units, determining a. The period P is 4.9 years. Hence

$$a^3/P^2 = (20.4)^3/(40)^2 = 3.5 = M_1 + M_2$$

We learn, therefore, that the combined mass of the two components is three and one-half times that of the sun If it is preferred to express the mass in tons, this can be done since the sun's mass is 1,980,000,000,000,000,000,000 tons.

To find the masses of the two stars separately we must determine their absolute orbits about their common centre of gravity instead of the relative orbit considered above. This means measuring the motions of the components with respect to surrounding stars instead of with respect to one another, It is found that

the bright star has the greater share of the mass, nearly in the ratio 3 I

From the visual double stars, together with the spectroscopic binaries (described below), an idea of the masses of stars in general has been obtained. Comparatively few determinations reach high accuracy, because a rather accurate parallax is reoured which is not generally forthcoming. The first thing that strikes us is the wonderful uniformity of mass. By fai the majority of the determinations give between one-third and three times the sun's mass, which seems a very small range when compared with the great differences of luminosity. Another result brought out is the close relation of mass to luminosity, the brighter stars being the more massive. It is probable that (excluding a peculiar class of stars known as white dwarfs) the luminosity depends almost entirely on the mass; it makes little difference whether the star is in a dense or in a diffuse state. The theory of this relation will be explained later Having checked it by the masses determined for double stars, we can use it to find the masses of other stars whose absolute brightness is known

We naturally select the most conspicuous stars for special investigation, and as a result we tend to pick out exceptionally inwestigation, and as a result we tend to pick out exceptionally inmasses. Among the spectroscopic binaries some very high masses have been found, which, however, are believed to be exceptional. For one binary of Type O discovered by J. S Plaskett the components have masses greater than 87 and 73 in terms of the coulding the properties of the control of the control of the conponents have masses greater than 87 and 73 in terms of the summasses 36 and 34. The eclipsing variable V Puppis has twoponents each of mass 19 2. There is at present no evidence of any stellar masses below one-sixth of the sun's mass.

From the close uniformity of stellar masses it follows that the stars of gigantic volume like Betelgeuse must be of extremely low density. Assuming that the mass of Betelgeuse is something less than 100 times the sun's mass, in order to fill a volume 50,000,000 times greater than the sun, the density must be less than  $\frac{1}{100}$  that of air. The small compact stars, like the companions of Siruis and Procyon, which are of planetary dimensions, must be of extremely high density, many thousands of times that of water. The large, diffuse, highly luminous stars are called gunt stars; the stars of low luminosity, which are smaller and of higher density, are called durn't star.

Spectroscopic Binaries.—When a source of light is approaching us, the lines in its spectrum appear displaced towards the violet end: when receding, the displacement is toward the red end. By means of this "Doppler effect" (see Light) the velocity of a star in the line of sight can be measured. In examining the stars with a spectroscope we sometimes turn the instrument on to what is telescopically a single point of light, but is actually a double star with components too close to be separated. Since the two components have different velocities toward or away from us their spectra will not be exactly superposed and every spectral line will appear double. The first example of this was found by E. C. Pickering in 1889. This was the star Mizar already mentioned as the first visual double star to be discovered. The two components seen in the telescope take at least 3,000 years to perform their revolution; but the doubling of the spectral lines of the brighter component shows that it is itself a double star with a revolution period of 104 days. If a star showing a doubled spectrum is watched for some time it is seen that the doubled lines close up and then cross one another This is in accordance with the theory of orbital motion, for the two components must approach us and recede from us alternately in the course of a revolution.

It is only when the two components are of nearly equal brightness that this doubling of the spectral lines can be observed A difference of about two magnitudes is sufficient to render the finiter spectrum invisible. In the majority of spectroscopic binaries only the brighter spectrum is observed, and the binary character is inferred from the periodic approach and recession of the source emitting it. The argument is that the changing displacement of the spectral lines shows that the source of light is describing an orbit; there must be some mass for it to revolve around; and therefore a fainter component must exist although invasibe About 1,500 spectroscopic binaries have been discovered, and definite orbits have been computed for about 400 of these The spectroscope can only measure velocity in the line of sight, and many binaries must escape detection through having their orbits nearly perpendicular to the line of sight.

Spectroscopic binaties, afford valuable additional information as to the masses of statis, but of a statistical rather than of an individual kind. When one component only is observed, all that can be deduced is a rather complicated function of the masses and the unknown inclination of the orbit; but when both spectra are observed, a minimum mass of each component can be found. This minimum mass has to be multiplied by cosec? a (s-inclination of orbit plane to the sky plane) which is unknown unless the star can also be observed visually or is an eclipsing variable, but in researches on the average mass of any class of stars a

suitable mean value of this factor may be used

and an electronic to a state of may be observed as a visual and a spectrostopic burn's but in general only the close pairs with person of the close pairs with person of the close pairs with person of the person o

Multiple systems containing more than two components are not uncommon We have already noticed the system of Mizar. The star Castor is an easy visual double, both components of which are spectroscopic binaries These systems all appear to be built by successive subdivisions of one mass into two, and it is clear that after such a fission a long period of evolution and condensation must elapse before either of the resulting masses is ready to divide again. An important question is whether the widely-separated pairs were originally formed with their present separation or whether the distance has increased in the course of time. It is difficult to resist the impression that the components gradually recede from one another, especially as the statistics show markedly that the stars supposed to be oldest in evolution form the widest pairs. Two causes are acting which will tend to increase the initial separation to some extent, viz., the mutual tidal forces and the loss of mass of the stars by radiation; but neither can produce a large effect. The cumulative effect of perturbations by casual approaches of other stars would in the long run, drive the components further apart; this process, however, is too slow to produce much effect, even in the long periods of stellar evolution The general problem of the formation of double stars is discussed in the article Cosmogony.

# VARIABLE STARS

There are three main classes of variable stars: (1) eclipsing variables, (2) Cephied variables, (3) long period variables. In a sense the sun is a variable star, since the changes of its surface condition which follow the suspect cycle of 1rly years must anvolve some small variation in the rate of emission of light and heat (see Suv.) but this is not analogous to any of the recognised forms of stellar variability. Nowae or "new stars" might also be counted technically as variables; it is, however, no longer be-lieved that they have anything in common with the ordinary types of variables, and we shall not include them here. (See Nov.).

Retipsing Variables—In this type of variation there is no physical change in the star. It emits light steadily all the time, but it is occulted at times by another body passing in front of it. The present explanation dates from 1798, when John Goodricke, having discovered the regular-period of fluctuation (2<sup>4</sup> 20<sup>4</sup> 49<sup>89</sup>) of the variable star Algol, suggested that the periodic dimming was caused by a dark body revolving round it and ethissing it once a revolution. Knowing, as we now do, that there

are multitudes of close binary systems, it is only to be expected that we should sometimes observe an eclipse of one component by the other. Each system will provide regularly recurring eclipses for observers stuated sufficiently near the plane of the orbit, the eclipsing variables are therefore ordinary binaries whose orbits we happen to be viewing nearly edge on. For Algol and many other variables of this class it has been venified that the object is a binary system, and that the decline of light occurs when the principal star is in the part of its orbit most remote from us, which is the time when the second component would intervene

It is not necessary to assume that the intervening object is a dark body Even if the system consisted of two equal stars a total eclipse of one by the other would halve the light received in most systems that have been studied, one component is considerably brighter than the other, but the light of the second component is quite recognisable. Half a period after the main eclipse, when the faint star occults the brighter, a secondary eclipse is observed owing to the bright star occuling the fainter There is, of course, a considerable period when no eclipse is occurring and the system shines steadily with its maximum light (By this feature eclipsing variables are easily distinguished from all other types). The steadiness in these intervals is, however, only approximate, and is complicated by two phenomena of singular interest.

(1) Reflection Effect—Systems in which the two stars are very click together have the best chance of showing echipses, since the orbit does not then need to be so accurately orientated with respect to our terrestinal post of observation. The closeness of some of the best-known echipsing variables is remarkable, the components being separated by no more than their own diameter. Each is therefore strongly illuminated by the other, and the hemisphere turned toward the companion becomes heated and shines more brightly than the other hemisphere For the fainter star in particular, the disparity in brightness of the two hemispheres is considerable, and as it moves round its orbit it exhibits variations of brightness analogous to the phases of the moon Owing to this reflection effect, the end of the principal celipse is followed by a gradual brightening, which continues until the dup representing the secondary echipse begins

(2) Ellipsoidal Effect.—Owing to their close proximity the two stars are distorted, being clongated toward one another. Thus, in addition to the variation due to eclipses and reflection, there will be a variation depending on the aspect of these clongated objects. Their apparent sections will be smallest when we see them end-on near the time of the eclipses; halfway between eclipses we see the prolate spheroids broadside-on and correspondingly brighter.

We may hope ultimately to learn much as to the physical state of the stars from these two effects; but, microtrusately, they are only just within our range of detection, and it is difficult to obtain accurate measurements of their amount. Meanwhile, an examination of the light-curve during the echipes teaches us much about the dimensions of the system. The method of analysing the light-curves was developed by H. N. Russell and H. Shapley, for an example of the results obtainable see Alcoia. As a rule the fainter component is found to have the larger diameter although it has the smaller mass; i.e., the companion is one of the giant diffuse stars of fairly low density and surface temperature. The colipses are usually partial, but are in a few stars total or annular. The number of ecloping variables known at present is about 200.

Cepheid Variables—Like the preceding class the Cepheid variables have short periods seldom exceeding 20 days, but the cause of the variation as entirely different. A very agantican fact is that the colour of the light (or the spectrum) is different at maximum and minimum light, showing that the star undergoes an actual physical change The surface temperature is much higher at maximum than at minimum, and, in fact, the changes of brightness may be ascribed to the changes of temperature. It is probable that the Cepheid variable is a pulsating star—a globe which swells and contracts with a regular period. Leaving aside the question as to how the star comes to let this-oscillating state, the pulsation theory agrees with the main phenomena The alternate compression and rarefaction naturally produces the

324 changes of temperature; moreover, the approach and recession, as the part of the surface presented toward us heaves up and down, is observed and measured spectroscopically. The most striking confirmation is the agreement of the theoretical period of such a pulsation with the observed period. The natural free period of a pulsation of a spherical mass of gas should vary approximately as the inverse square root of the density, and the observations show that the Cepheids closely follow this law; moreover, the absolute value of the period can be calculated (with a small margin of uncertainty due to our ignorance of the chemical constitution of the star's interior) and the observed period is found to agree On the other hand, no satisfactory theoretical explanation has yet been given of the phase-relation between the velocitycurve and light-curve. The mathematical theory of a pulsating star seems to show that maximum brightness must occur at the

moment of greatest compression, whereas in all the more typical

Cepheids it is found to occur a quarter-period later.

The study of Cepheid variables is likely to lead to results of the greatest importance, since they give the opportunity of observing stellar matter in motion, thereby extending the information obtainable from the ordinary static stars. They are important also for another reason. In 1012 it was noted by Miss Leavitt that, when the periods and apparent magnitudes of the variables in the Lesser Magellanic Cloud were plotted as abscissae and ordinates, the points lay on a smooth curve. Since the stars in the Cloud must all be at approximately the same distance from us. this indicates that the absolute brightness is a definite function of the period. H. Shapley subsequently found the same uniformity in a number of globular clusters. The same period-magnitude curve is repeated in each cluster, except that the curve is dis-placed as a whole towards fainter or brighter (apparent) magnitude, according as the cluster is remote or near It follows that Cepheids of the same period have the same absolute luminosity, and presumably are alike in all respects. The absolute brightness being identical, the apparent brightness indicates the distance: e.g., if the apparent magnitude of the Cepheids of 5-day period in a particular globular cluster is 13 we know at once that the cluster is 100 times as distant as a Cepheid of apparent magnitude 3; if the 5-day Cepheids observed in a spiral nebula have apparent magnitude 18, the nebula is ten times more remote than the cluster Thus the general structure of the universe can be plotted out to scale. The scale is made absolute by a study of the brighter and nearer Cepheids which are not beyond the range of ordinary methods of distance determination. The Cepheids are stars of high intrinsic luminosity, which are visible at great distances; practically all our knowledge of the distances of the more remote objects of the sidereal universes has grown up from the study of these stars. The only caution required in using these variables as standard lights for gauging distance is that we must have evidence whether their light has been dimmed by passing through absorbing matter. It is known that the interstellar spaces contain extremely diffuse matter in the form of atoms, molecules and particles of dust, which causes both a dimming and a reddening of the light from distant objects. This matter is concentrated near the plane of the Milky Way, but is not uniformly distributed. Allowance can be made for the average effect of the dimming produced by it, but there is necessarily some uncertainty in the individual distances derived for remote objects in the Milky Way regions,

and the therefore it is also dispersion to minky way regular. No theoretical basis for the period-magnitude relation has yet been send of the best of the same than the period of the period described of the period of the best of the period of the

The typical Cepheid variable which has given its name to the class is  $\delta$  Cephe I its period is  $\varsigma$  366 days. It is seven magnitudes brighter than the sun, and is believed to have about mise the sun's mass. It is a giant diffuse star having a radius of zo million kilometres, which changes by  $\pm 1.2$  million kilometres in the course of the pulsation. The light-trange is  $\sigma$  6 mag, visual and 1.0 mag photographic, the difference being due to the fact that the light becomes much bluer at maximum brightness. The "cluster variables" are a subclass of the Cepheids; they have very short periods usually about 12 hours. The shortest period known is 3 22 hours.

Long Period Variables.—There are very few variable stars with periods between 30 and roo days, but beyond roo days and especially near 300 days they become numerous again. The numbers within given limits of period are:

Days	100-200	200-300	300-400	400-500	500
Stars	64	194	182	54	12

The leading characteristics of these long-period variables are (i) their light-range is very great averaging 5; magnitudes, and in a few stars exceeding 8 magnitudes; (2) the variations do not repeat themselves with the clocklike precision of the other classes of variables, and both the amplitude and period influctual erregularly; (3) they are red stars, chiefly of type M, but sometimes of the rarer spectral types R. N, S; during the great outbust of light at maximum, bright emission lines of hydrogen appear in the spectrum.

The enormous variation of light is rather misleading to us, because there is no such large variation in the output of heat. The surface-temperature is varying through a range which happens to be especially critical for the sensitiveness of the human eye. The following results relate to Mira Ceti which is the most famous star of this type (discovered by Fabricius about 1506). To the eye at minimum it appears as a faint star of magnitude 9, difficult to distinguish from the numerous other minth magnitude stars in the field; but the more impartial bolometer, which measures the total radiant energy or heat received, singles it out as a very conspicuous object of bolometric magnitude 1.5. At maximum the surface temperature has risen a little, causing a moderate increase of radiation and bringing it up to bolometric magnitude o 2, at the same time the character of the radiation becomes more suited to the sensitiveness of the eye, so that an enormous increase of visual brightness occurs. At maximum Mira is generally between mag. 3 and 4 (visual), and occasionally it reaches mag. 2. Accordingly the variation of heat output is not much more than one magnitude, and is much the same as in the Cepheid variables. It is now generally believed that the long-period variables are pulsating stars not essentially different from the Cepheids. They are very diffuse stars of great bulk, and this extreme physical condition is probably responsible for the differences of behaviour between them and the typical Cepheids. Pease has measured the angular diameter of Mira, obtaining the result o".056. It is probable that the star has a radius of at least 1.5 astronomical units or 300 times the radius of the sun.

A number of minor classes of variables are recognized, which differ in material respects from the three chief classes here described. The whole subject of variable stars is now one of the most active branches of stellar research.

### STELLAR MOTIONS

We learn about the motion of a star in two ways. Firstly, the change of position in the sky can be observed directly by making from time to time accurate measurements of the position with respect to surrounding stars. The motion thus detected is called proper motion. It is measured in seconds of are per year; if the distance of the star has also been measured, the result can be converted into miles per second. Secondly, by measurements of the positions of lines in the star's spectrum, the speed of approach or of recession can be found; this radial velocity is given immediately in miles per second, whether the distance of the star is known or not. The two methods supplement one another, the

first giving the motion transverse to the line of sight, and the second the motion in the line of sight; combining them we obtain the direction and speed of the whole motion

Proper Motions .- The stars differ greatly in proper motion. For a naked-eye star a motion of about 3" per century may be taken as typical The corresponding change of position would be measurable without difficulty in an interval of ten years. For some stars the displacement is less, either because their actual speeds are small, or because their motion is mainly in our line of sight, or because they are very distant. Other things being equal, the stars which are especially near to us will have large proper motions. Just as great apparent brightness may be due to nearness or to high intrinsic luminosity, so great proper motion may be due to nearness or to high actual speed; but, in general, great proper motion is a much more dependable indication of nearness than great apparent brightness, and it is used as a criterion to pick out stars likely to have measurable parallaxes from the great majority which are too far away to be measured Proper motions have been measured in tens of thousands; and, moreover, there are methods of quickly detecting stars of large proper motion on a pair of plates of the same region taken at a suitable interval of time (see Blink Microscope).

The star of greatest proper motion known up to the present is a ninth magnitude star discovered by Barnard, which travels 10½" per year (more than 300 times the typical speed mentioned above). Even at this speed it would take about 900 years to go from end to end of Onon's belt. The following table gives particulars of the stars of largest proper motion

Star		Ann	Dist	Spe	Lum.	
Star	Mag P.M.		(LY)	Trans	Rad	Lum.
Barnard star	97	10" 25 8 76	60	90	-117	0004
Kapteyn star Groombridge 1830	9 2 6 5	7 05	10 3 32 0	330	+242 - 97	23
Lacaille 9352 Cord 32416	7.4 8.3	6 90	11 2	112	+ 12 + 26	000
61 Cygni .	56	5 20	10.9	82	- 64	.058

The distance in light-years is given in the fourth column; the transverse and radial speeds are given in m. per sec. in the fifth and sixth columns, the last column gives the intrinsic lummosity, the sum's lummosity being the unit. If will be noticed that these are all inconspicuous stars, fant both apparently and actually. Well-known stars which come further down the list are \( \alpha \) Cartain and Arcturus, with annual proper motions 3"66 and \( a^2 \), a respectively. The motions cannot have caused any noticeable change in the appearance of the sky with mistoric times; but the change in, say, 25,000 years would be considerable, and it is doubtful if any of the familiar constellations except Orion would be recognizable. When the parallar is known, proper motion is convected into linear measure by the formula:

The Solar Motion .- If we examine the proper motions in any small region of the sky, it is at once evident that they are not directed at random; an average motion in a certain direction is plainly shown. Comparing different regions of the sky and allowing for the different aspects of projection, it is found that the stars in the mean are moving in a direction toward the southern constellation Columba, not far from the south part of Canis Major. The same average motion is also shown by the spectroscopic radial velocities; i.e., the stars in the Columba region have an average motion away from us, whilst those in the opposite part of the sky have an average motion towards us The effect is so pronounced that a dozen stars taken at random will be sufficient to show the prevailing direction roughly (the first determination by Sir William Herschel was made from seven stars only); but in attempts to fix this important direction as accurately as possible many thousands of stars have been used.

In measuring proper motion, or radial velocity, our standard of reference is the sun; and the foregoing result shows that the stars

in the mean are travelling past the sun in the direction toward Columba. This, however, is rather an egocentric way of expressing the facts It is more natural to say that the sun is travelling relatively to the mean of the stars in the opposite directiontoward a point in Hercules or Lyra not far from the bright star Vega This point is called the solar apex, and the relative velocity that is found is the solar motion. Attempts to determine an accurate position of the solar apex are not very closely accordant. In particular, radial velocity determinations seem to give systematically a lower declination than the proper motions, and bright stars give a lower declination than the faint stars. It is now generally agreed that systematic errors in the proper motions are mainly responsible for these differences We could scarcely expect the apex to be definite, because the "mean of the stars" is an indefinite conception. The stellar background appears to consist of interpenetrating clusters with different motions, and the relative solar motion will depend on what part of this background is sampled by our observational data. In round figures the general result is Solar apex, R.A 270°, dec +30°, speed 20 km per sec In measuring the parallaxes of stars we use the diameter of

the earth's orbit as base line-a length of two astronomical units. The solar motion of 20 km per sec. transports the observer through 4.2 astronomical units per year, so that observations taken now and 50 years ago give us a base line of 210 astronomical units With the longer base line it is possible to survey the stellar system to a distance far exceeding that attainable by parallax measurement. The method cannot be applied to individual stars because the parallactic displacement cannot be discriminated from the star's own motion, but when we are dealing with a class of stars (eg., stars of 9th magnitude, bright stars of type K, long-period variables, etc.) which are not likely to have any important common tendency of motion as compared with the general mean of the stars, the method will give the average parallax of the class. Fortunately, results obtained in this way can be checked by an independent determination based on similar principles. The cross proper motion, or component at right angles to the line towards the solar apex, is a component of the individual motion of the star, the radial velocity (after correcting for the known solar motion) is also a component of individual velocity. Hence, for a class of stars we can find the average value of a component of individual velocity both in arc and in linear measure; comparing the two results we deduce the mean distance These methods have proved extremely useful in supplementing the meagre knowledge of the distances and absolute luminosities of the stars furnished by direct parallax determinations. For still greater distances the method described under Cepheid Variables and analogous methods are employed.

Moving Clusters.-A number of groups of stars have been recognized which share a common proper motion, and evidently form a connected system. We must assume that they have a common origin, i.e., are evolved from the same nebulous con-densation. Apparently, having started to move together, they continue to move together simply because encounters which might deflect them are extremely rare. One of the arguments against the existence of great numbers of dark stars in space, is that their passage between the stars of the moving cluster would break it up too rapidly There is a typical moving cluster in Taurus, studied by L. Boss, which includes many of the stars in the Hyades. The true motions of these stars must be very nearly equal and parallel, otherwise the cluster would rapidly disperse, but as projected on the sky they appear to converge toward one point. As the cluster covers a reasonably large area the convergent point can be found with considerable accuracy. By geometrical construction it becomes possible (without parallax measurement) to determine the distance of each star of the group and to find the precise arrangement of the stars in three dimensions. Another cluster consists of five stars of the Plough together with Sirius and some other bright stars; the sun is in the middle of this moving cluster, so that its members appear in different parts of the sky. The stars of type B seem to have a special tendency to form associations of this kind: one of the best marked groups consists of about 16 stars in Perseus and neighbouring constellations. Perhaps the most important conclusion to be drawn from these clusters is that the stars are not born individually and independently, e.g., by accidental collisions of extinct stars, but that the evolutionary process of star formation is capable of generating a number of stars simultaneously

The Two Star Streams .- Eliminating the recognized moving clusters, we are left with the general body of the stars whose motions have no obvious association with one another. It is found on examination, however, that their motions are not at random. In 1904 J C. Kapteyn showed that the proper motions show a decided preference for two favoured directions, apparently implying that the stars around us do not constitute a single system but a dual one The observed motion of the stars in the mean towards the solar antapex is due to the intermingling of two systems moving in very different directions. These two streams are found to prevail in every part of the sky examined; they are shown both in the proper motions and in the radial velocities. It is not likely that the same stream motion extends throughout the galactic system, but up to the present no limit has been found. Originally discovered in the motions of the bright stars, the phenomenon is found to be essentially the same in stars as faint as mag. 11 5, and there is evidence of its occurrence in much fainter stars. The following determinations of the apices and relative speeds of the two streams refer respectively to the bright stars of Boss's catalogue (Eddington) and the Cambridge photographic proper motions of faint stars (Smart). The speed is expressed in terms of a theoretical unit which is probably about 22 km, per second.

	Bright stars			Faint stars		
	RA.	Dec.	Speed	RA	Dec	Speed
Apex of stream I "" II Vertex Solar apex	91° 288° 94° 267°	-14° -64° +12° +36°	1 52 0 86 1 87 0.91	88° 289° 92° 273°	-12° -73° +20° +44°	

The first two lines give the motions of the streams relative to the sun, but greater cosmical importance must be attached to the motion of one stream relative to the other, which is given in the third line of the table. The principal difference between bright stars and faint stars lies in their distribution between the two streams. For the bright stars the numbers belonging to stream I and stream II are as 3:2; for the faint stars the numbers in the two streams are practically equal. It is partly for this reason that the declination of the solar appear increases progressively with the faintness of the stars; considered; stream II is receiving more and more weight in the "mean of the stars,"

If two interpenentating streams of stars exist, moving relatively to one another in space, all that can be learned about their motions is the direction and magnitude of their relative motion. Schwarzschild pointed out that the observed phonomena can be explained by supposing that the stars have a greater freedom of movement in a certain direction than in other directions or, in other words, that there is a preferential direction of motion of the stars, instead of the motions being at random. The direction of preferential motion lies in the plane of the galaxy and neaty, but not exactly, in the directions toward and away from the galactic centre.

Stars of type B are aloof from the two star-streams. Their motions (relative to the mean of the stars) are smaller than those of other types, and show little systematic tendency of any stars of other types are associated with them and form a third stream, known as stream O. In most parts of the sky it is difficult to disentangle stream O from stream I, but he regions where the circumstances of projection are favourable the little stream slavays appears clearly.

Rotation of the Galaxy—If the galactic system is analo-

MOTATION of the Galaxy—If the galactic system is analosous to a spint abelial its presumably rotating in its own plane; in any case its flattened form would lead us to suspect rotation. If the rotation were like that of a rigid body the radial velocities, as viewed from any point, would be unaffected, but it is more reasonable to suppose that the angular velocity diminishes out-

wards from the centre of the system, as with the planets in the solar system Then, if we take a group of stars surrounding the sun, those between us and the centre will be gaining on us and those outside us will be lagging behind. This shearing motion distorts a square into a parallelogram, that is to say one diagonal is lengthening and the other diagonal is shortening, so if we observe stars in two opposite regions of the sky, corresponding to the direction of one diagonal, these should be receding from us. and along the other diagonal, 90° away, the stars should be approaching us, on the average J H. Oort has found that this effect is quite prominently shown in the observed radial velocities. and that the direction of the galactic centre deduced from it accords well with the direction generally accepted (deduced from the distribution of globular clusters and other classes of distant objects) Moreover, taking different classes of stars, the positions found for the centre are very accordant, and the effect increases, as it should do, proportionately to the mean distance of the class. Oort's results have been fully confirmed by J S. Plaskett, from the analysis of his measures of the radial velocities of stars of types O and B, which are particularly suitable for the purpose, because of their high intrinsic luminosities. The rotation of the galaxy has also been investigated by using the proper motions of the stars, though this method suffers from the drawback that the greater the distance of the star, the smaller is its proper-motion

The analysis of the radial velocities of stars at different disances gives the change of velocity throughout the region covered by the survey, but does not give the actual velocity at any point. The velocity in the neighbourhood of the sun can be found from the radial velocities of the globular clusters, which extend well beyond the centre of the galaxy. The velocity is found to be about 300 km. per sec., but is subject to a somewhat large probable error. The distance to the centre of the galaxy and the mass of the system whose gravitational attraction controls the orbital motion can be determined when reasonable assumptions about the distribution of the mass in the system are made. The distance to the centre is some 30,000 high-years, the period of rotation at this distance is about 200,000,000 years and the total mass of the system is about to 6 thousand million times the mass of the system is about to 6 thousand million times the mass of the system is about to 6 thousand million times the mass of the

It was suggested by H. H. Turner that the preferential direction of star-streaming was toward the centre of the galaxy: he pointed out that the comets of the solar system, because of the elongated shape of their orbits, have a preponderatingly radial direction of motion. Situated, as the sun is, at some distance from the centre, the directions to and from the centre appear as the favoured direction of southout. The direction of preferential motion deviates by about x2° from the direction to the galactic entre; it is doubtful to what extent this deviation is significant. B. Lindblad has suggested that a satisfactory agreement can be obtained by taking into account not merely the general gravitational effect of the system as a whole but also the local gravitational fields due to star clouds and local aggregations of stars.

Individual Motions.-After eliminating all systematic motion there remains the individual motion of the star itself. An interesting field of study arises from the correlation between individual speed and other characteristics, such as mass, spectral type, brightness. The earliest result of this kind was found by W. W. Campbell and J C. Kapteyn in 1910; viz., a progressive change of mean speed with spectral type Campbell's results for bright stars were. Type B, 6.5 km. per sec.; A, 11, F and G, 15; M, 17 km. per second. The figures refer to the radial component only, and must be doubled to give the mean speed in three dimensions. At the time it was thought that this sequence of types represented the order of evolution, so that the progression implied that the speed of the stars increases with their age; with the recognition of giant and dwarf stars this interpretation has become inadmissible. Actually type M consists of two distinct classes, viz., very diffuse stars supposed to be in an early stage of condensation from a nebula, and very dense stars supposed to be at a later stage of the evolutionary sequence; both classes have high speeds, the latter being particularly large. Generally speaking, faint stars have greater speeds than bright stars; owing to the

mass-lumnosity relation this means that stars of small mass have greater speeds than massive stars. It has been suggested that there is a law of equipartion of energy so that the average value of \( \frac{1}{2}\) mu^3 is the same for all classes of stars, this might have a dynamical explanation, since the speeds of the molecules of a ga distribute themselves according to the same law. Up to a certain point observations agree with the equipartion law, but there are noteworthy exceptions, the massive B stars have low average speed as the law requires, but the most massive stars of all, type O, have rather large speeds. The present position is that our knowledge of the factors determining the mean speed of different kinds of stars is made up of fragmentary correlations, and has not yet led to any exemptly commerchancy theory.

One complicating factor is the asymmetry of high velocity stars, which was discovered by J H Oort and G Stromberg Stars with speed greater than about 80 km per sec. are moving almost exclusively toward one hemisphere of the sky. The group as a whole is moving nearly in the galactic plane and at right angles to the direction to the centre of the system, so that it lags behind the average of the stars at the same distance from the centre by about 80 km. per sec. No stars with velocities in excess of the average by a similar amount are observed. Any such stars originally present in our local star-cloud have been lost to it because their velocities have exceeded the "velocity of escape" Stars with velocity below the velocity of escape are permanent members of the system, and describe orbits within it under its gravitational attraction; on the average, therefore, they move as much in one direction as in the opposite. Stars with velocity above that of escape cannot be permanent members, they pass once through the system and do not return, accordingly they may well show an asymmetry of motion, dropping into our local star-cloud from a cluster or clusters on one side of it, passing through it, and not returning The value of the velocity of escape is more or less what we should expect from our general knowledge of the extent of the star-cloud and the number of stars per unit volume

About 25 stars are known within a sphere of 4 parsecs radius surrounding the sun, s.e., having parallaxes greater than o"25; there may be a few additional faint stars yet to be detected. Many of these near neighbours are red dwarfs with masses onequarter or one-fifth that of the sun; on the other hand a considerable proportion are double stars (here counted as one) The total mass within the 4 parsecs sphere may be estimated at about 17 times the sun's mass In addition to the mass of the lucid stars there may be other masses in the sphere, e.g., dark stars, in addition to scattered nebulous matter of great tenuity. There is direct observational evidence, referred to at the end of this article, for the existence of a cloud of diffuse matter in interstellar space. It is extremely rarefied; one atom per cubic centimetre is the most we can possibly allow consistently with the dynamics of stellar motions Even so, the total mass of this rarefied matter in the galactic system is comparable to the total mass of the lucid stars.

#### CONSTITUTION OF THE STARS

Density.-When the mass and radius of a star are known. the mean density of the material can be calculated immediately. Direct determinations of the mass are only available for double stars; but for other stars the mass may with some confidence be inferred from the absolute magnitude by means of the massluminosity relation described later in this section. In any case the range of stellar masses is so restricted that errors are not likely to affect the general order of magnitude of the densities deduced. The radius R may be calculated from the absolute luminosity and the observed surface-temperature. In this way we find that some of the red giant stars, such as Betelgeuse, Antares, Mira, have densities less than  $\frac{1}{160}$  that of air; Capella has a mean density nearly equal to air; the sun, we already know, has a density 1.4× water, the faint red dwarfs have density about 10× water For the class of stars called white dwarfs, which includes the companion of Sirius (see SIRIUS), the method gave an enormous density 60,000 times that of water; this result was at first regarded as incredible, but it is now clear that it is to be accepted literally.

For the more diffuse stars it is evidently legitimate to treat the stellar material as perfect gas. The study of stellar equilibrium thus reduces to the study of the equilibrium of a globe of perfect gas held together by its own gravitational attraction It was thought that the simple theory must break down for stars of higher density (such as the sun) owing to the deviations from the laws of a perfect gas, but in 1924 it was found by Arthur S. Eddington that the dense stars agreed observationally with laws which had been deduced theoretically for gaseous stars. The fact is, that at the temperatures of the order of 10,000 000 degrees occurring in the stellar interior, the atoms are stripped of all their outer electrons and reduced to ions of very small dimensions; consequently the samming of atoms against one another, which causes the breakdown of the gas laws, does not occur in the stars until far higher densities are reached. The high density found for the white dwarfs confirms this conclusion, close packing is possible because the atoms have lost their balloonlike envelopes. In all stars other than white dwarfs the material may be treated as perfect gas, except that in the stars of least mass (red dwarfs) there is a small correction arising from the electrostatic forces between the ions which makes the gas superperfect, i e, makes it deviate in the opposite direction to the deviations of imperfect terrestrial gases

Internal Temperature and Pressure.-The distribution of temperature and density in a sphere of gas in equilibrium under its own gravitational attraction is a classical problem studied by Lane, Ritter, Emden and others. The mathematical analysis developed in these earlier researches is used in the modern theory, but three new features have been introduced (1) It used to be supposed that the heat radiated from the star's surface into space was brought up from the interior by convection currents, but it has now become evident that it is transferred by radiation Accordingly the stars are now assumed to be in radiative equilibrium instead of in convective equilibrium. The condition of radiative equilibrium is that each region must have settled down to a temperature at which it ladiates an amount of heat equal to that which it absorbs from the radiation passing through it. One simplification resulting from this change is that we no longer need to know the ratio of specific heats of stellar material-a physical constant difficult to estimate, (2) Radiation-pressure is sufficiently great to play an important part in the equilibrium, especially of the massive stars, and it is now taken into account. (3) Formerly the average molecular weight of the stellar gas was taken to be the weight of the atoms likely to preponderate, e g, iron (at. wt. 56). It is now recognized that the atoms in the interior will be highly ionized; most of the electrons which circulate round the nucleus will have broken loose, and must be counted as independent "molecules." Taking this into account the molecular weight will be slightly over two, a result nearly independent of the chemical constitution of the star provided only that there is not an excessive proportion of hydrogen. Owing to this decrease in the adopted molecular weight, the internal temperatures are considerably lower than those calculated on the older theories

Since it is believed that a star's heat is maintained by liberation of substonic energy, another unknown condition enters into the problem, viz, the distribution of substomic sources in the interior. This, however, has no very important effect on the main results of the investigation, and, by considering the extreme case of a source wholly connectrated at the centre and a source evenly distributed through the mass, we can set limits to the uncertainty.

For the sun the central temperature is found to be of the order 20,000,000 °C. The mean temperature (averaged for equal mass) is about 12,000,000 °, and is less subject to uncertainty arising from ignorance of the distribution of the source of energy and other data Moreover, all stars of the Main Series (see STRILAR CONSTITUTION AND ENOLUTION) have nearly the same internal temperature. The Main Series, which comprises the great majority of the stars, includes B type stars several hundred times more luminous than the sun, and red dwarfs, giving a hundredth or a thousandth of its light. It is remarkable that stars differing so widely in mass, in output of heat and light, and in surface

temperature, should be so uniform in internal temperature. The giant stars have lower internal temperature,  $e\,g$ , Capella, which is of the same spectral type as the sun but has only  $\overline{a\,b\,a}$  of its

density, has a central temperature 6,000,000° The temperature gradient from the centre to the surface causes a flow of heat outwards, which is hindered by the opacity of the stellar material; hence, knowing the temperature distribution in the interior, and having observed the total outflow of heat from the star (s.e, sts luminosity reduced to heat units) we can compute the opacity This astronomical opacity may be compared with the theoretical opacity for material of the density and temperature concerned, as calculated from the modern theory of the atom The astronomical opacity is very sensitive to the assumed proportion of hydrogen in the star but, when this is given, the composition of the rest of the material makes very little difference. The luminosity of a star with the mass of the sun can range over seven magnitudes according to the proportion of hydrogen which it contains. Comparison between the astronomical opacity and the theoretical opacity consequently enables the proportion of hydrogen in the star to be estimated. For several stars for which first-class observational data are available, it is found that about one-third part by weight of each star consists of hydrogen There is some evidence that the most massive stars contain

a larger proportion of hydrogen.

In Mass-tuminosity Relation.—Having calculated the temperature distribution in the star by the condition of radiative equilibrium, we find the following formula for the total outflow of heat L (in ergs per second).

## $L=4\pi cGM(1-\beta)/k$ ,

where c is the velocity of light, G the constant of gravitation, M the mass of the star (in grams); k the coefficient of opacity, and  $z-\beta$  the ratio of radiation pressure to the whole pressure, obtained by solving the quartic equation,

$$I - \beta = 0.003 I M^2 \mu^4 \beta^4$$

where M is now expressed in terms of the sun's mass, and  $\mu$ is the average molecular weight in terms of the hydrogen atomic weight. Knowing L and M for any star we can calculate k; for example in Capella we find k=120 C.G.S. units. This means that a screen containing  $\frac{1}{120}$  gram. per sq.cm. (equivalent to about 6 cm. of air) would stop about two-thirds of the radiation passing through it At first sight this is a surprisingly high opacity The old problem as to how the heat is brought up from the interior of a star to replace that radiated from the surface, has completely changed; we see rather that the star has to be constructed of highly opaque material in order to hold back the internal heat and permit it to come to the surface no faster than it does. The high opacity is, however, not so surprising when we realize that at 10,000,000 degrees the radiation in the interior consists of X-rays chiefly of wave length 2 to 6 Angstroms, which are highly absorbed in a few millimetres of air. In fact the stellar opacity is less than the observed opacity in the laboratory-a fact explained by the high ionization of the stellar atoms, which throws a great part of their absorbing mechanism out of order.

According to modern theories of X-ray absorption, the coefficient of opacity should (approximately) be proportional to the density and inversely proportional to the 2 power of the temperature  $(k cc \rho/T_{\frac{\pi}{2}})$ . By the use of this law we can eliminate k from the equation given above and obtain the relation between L and M. The density of the star nearly disappears from this relation, so that the total radiation or absolute bolometric magnitude of a star is a function of the mass and molecular weight only, apart from a trivial correction dependent on the density, which can be calculated and applied when the spectral type is known. This predicted relation between L and M can be plotted as a graph; it is called the mass-luminosity relation. It appears to be well confirmed by all the observational data available; but it must be remembered that accurately determined masses are rare, so that the test is not so complete as we should desire. The mass-luminosity relation cannot conveniently be expressed by an algebraic formula, but as a rough guide it may be stated that the

heat outflow from a star varies as the third or fourth power of the mass in the most important part of the range.

ISTELLAR SPECTRA

These results are mamly independent of the assumed chemical constitution of the stars, owing to the fact that the average molecular weight for all elements except the lightest turns out to be nearly 2 when account is taken of ionization, but for stars composed mainly of hydrogen the mass-luminosity relation would be greatly altered It may be inferred, therefore, that stars of the same mass do not differ widely in their hydrogen content

It is interesting that we should be able to learn anything at all about the chemical composition of the inaccessible interior, but the fact has also a definite bearing on theories of the source of a star's heat. It is probable that the store of energy needed to maintain the star for thousands of millions of years is provided by the evolution of higher elements from hydrogen (Hydrogen which consists merely of protons and elections, is perhaps best regarded as informed matter) By cutting down the admissible proprion of hydrogen to, say, 10%, we reduce the supply from this source to one-tenth, and it becomes very doubtful whether it will suffice. Secondly, if we admit that 90% of the star must consist of "formed" matter, we must suppose that the man process of formation of matter occurs in a prestellar stage Evolution of the elements is, therefore, in the man a low temperature process and, pelhaps still more surprisingly, a low density process

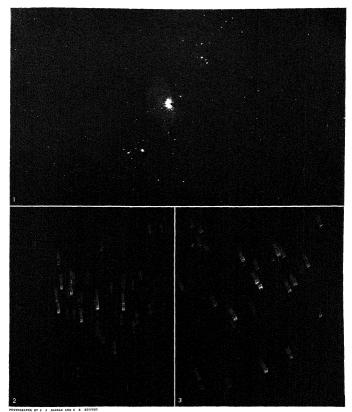

Radiation-pressure.-At any point in a star, gas-pressure and radiation-pressure together support the weight of the lavers above The proportion supported by radiation-pressure  $(i-\beta)$  is found by a quartic equation already given. To a first approximation it is the same in all parts of the interior, and is independent of the star's density; the molecular weight being given, it depends only on the star's mass. It is remarkable that for stellar masses there is no great disparity between radiation-pressure and gaspressure, whereas for masses of a different order  $1-\beta$  would or .99.. It seems clear that the condition of begin oo rough equality of the two pressures has in some way determined the size of the aggregations of the primitive matter of the universe The simplest view is to suppose that, when radiation pressure amounts to say one-tenth of the whole pressure, it renders the aggregation of further material more difficult or makes the mass more liable to break up. Hence larger masses are more and more rare. Gravitation by drawing together the primitive nebulous material will, in general, build up masses to a size at which radiation pressure first begins to offer serious opposition to further increase.

### STELLAR SPECTRA

We deal rather briefly with this branch of the subject since some of the more interesting developments are treated under ASTROPHYSICS; STELLAR CONSTITUTION AND EVOLUTION; SUN By the appearance of their spectra (see Spectroscopy) stars are arranged in a sequence of types O, B, A, F, G, K, M This turns out to be the order of decreasing surface temperature. The "effective" surface temperatures of stars are calculated by Planck's law of radiation (for theory, see Radiation, Rays) from the relative intensity of the continuous spectrum for different wave-lengths, the higher the temperature the more the region of maximum intensity is displaced to the violet. For the sun this method of finding the equivalent black-body temperature is checked by calculating also the temperature corresponding to the absolute intensity of its radiation, so presumably it will apply to other stars, although we have not usually any direct check. Good indirect confirmation of these temperatures has been afforded by studying the spectral indications of ionization of the elements. (See below.) The following temperature scale is a combination from various sources, the results are in degrees absolute

i		Type		Type Temperature		Type				Temperature
ı					-					
1	Во			20,000	Go				5,500	
1	B5 Ao			15,000	G <sub>5</sub>				4,700

PLATE STAR

KODACHROME PHOTOGRAPHS OF THE HEAVENS

- 1 Shows the great nebula in Orion, a sloud of dust and gas at least 10 light years in dismeter and at a distance of 600 light years. The older violet relation should be supported by the state of the s

These photographs were obtained with the 24 in. Schmidt-type taisappe at the Warner and Seway observatory of the Gass School of Seway (1994). One of 1994 were made by pisched to the control of the Carlo of the telescope. The light of such star is dispersed into its confined processing as proceedings aspection. The hottat size is star have a preast persentage of their light in the violet part of the spectrum whereast the cooler stars have not of their light in the red region whereast the cooler stars have not of their light in the red region

This refers to grant stars, dwarf stars of the same type are about 500° hotter. The radiating power of the surface in heat units is proportional to the fourth power of the temperature.

In all the later types the stars fall into two groups, the giant or diffuse stars, and the dwarf or dense stars. They are most widely distinct in type M, and converge to coalescence in types A and B If, instead of arranging the stars in order of surface temperature, we put them in order of increasing density, we must start with the giants of type M, follow the giant branch through K, G, F until it coalesces with the dwarf branch in types A and B, and then continue along the dwarf branch in the reverse order A, F, G, K, M. It seemed natural to suppose that the order of increasing density is that of evolution.

Following this supposed order of evolution, the temperature of the surface starts very low, increases to a maximum, and then decreases again, the giant stage being one of ascending temperature, and the dwarf stage of descending temperature. This fact has probably no great significance, since the surface temperature does not correspond at all closely to the internal temperature. It is more important to note that the mass (corresponding closely with the luminosity) is nearly steady in the giant sequence, perhaps decreasing slightly, and then diminishes rapidly as we pass down the dwarf sequence. It seems impossible to retain this idea of stellar evolution without admitting that the mass of a star must decrease substantially during its lifetime Radiation is the principal cause of loss of mass by a star, and hence it would follow that a large part of the mass of a star is convertible into radiation-in short, matter must disappear, its energy of constitution being released as aether waves. Admitting this source of energy, the age of the stars is of the order of a billion (1012) years or more But there is strong evidence against so long a life and in support of a much shorter age of several thousand million years. A large part of the mass of the star could be converted into radiation only if the actual annihilation of matter, by the combination of protons with electrons to produce radiation, were to occur within the star. This would require, however, a temperature very much higher than is found within any star. According to views current in 1945, the main source of stellar energy is provided by the building up of atoms of helium from atoms of hydrogen. In this process, not more than 1% of the mass of the star would be lost. Up to 1945 no plausible theory of the course of stellar evolution had been expounded.

After the first use of spectroscopy to identify chemical elements in the atmosphere of a star, the most important advance was the discrimination of "enhanced lines," i.e., lines strengthened in the spark spectrum as compared with the arc. Much of the early progress in this direction was due to J N. Lockyer and A. Fowler. In general, enhanced lines are those due to the atom with one electron missing (singly ionized atoms), the arc lines being due to neutral atoms. The spectra of all the important elements have now been unravelled, and we can say at once which lines belong to neutral atoms, which to singly ionized, which to doubly ionized atoms, etc Thus it is found that in some stars the atoms of calcium in a position to form an absorption spectrum are neutral, in others they are singly ionized, in others doubly ionized Clearly this is a clue to the physical conditions in the outer layers of a star. The modern thermodynamical theory of ionization was brought to bear on the astronomical observations by M. N. Saha in 1920, and has dominated all later progress. The degree of ionization depends on both the temperature and pressure, the former representing the factor which causes the breaking away of electrons and the latter the factor which determines their opportunity of recombining. By connecting together the data for different elements and controlling the results by reference to other methods of determining stellar temperatures, much information has been obtained as to the temperature and pressure in the reversing layer. In particular it is found that the pressure is generally between 10-3 and 10-4 atmospheres-much lower than used to be supposed.

Spectroscopic Parallaxes.—Since the nature of the spectrum

shown by a star is conditioned both by the temperature and pres-

should be two-dimensional Ordinarily we recognize only a linear series-the Draper sequence of types considered above; but by attention to detail we can recognize also a classification transverse to this. Taking the Draper sequence to correspond roughly to temperature, the transverse classification will correspond to pressure Since low pressure favours ionization, it will be marked in the spectrum by great strength of the enhanced lines relatively to the arc lines The giant and dwarf stars of the same spectral type can easily be distinguished from one another by this method; the reversing-layer pressure is low in the giant stars owing to the small value of gravity at the surface.

It was early recognized by E Hertzsprung that those spectra marked by Miss Maury as having the "c-characteristic" belong exclusively to the giant stars. This characteristic is an unusual fineness of the lines-a feature which also results from low pressure. More precise criteria were found by Adams and Kohlschutter in 1914; and the method has been developed by Adams into a means, not only of distinguishing giant and dwarf stars, but of determining quantitatively the absolute luminosities of stars. At present the procedure is empirical, the curve connecting absolute magnitude with differential intensity of certain selected pairs of spectral lines is deduced from and tested by stars of known trigonometrical parallax, it is then applied to find the absolute magnitudes and hence the distances of other stars. Parallaxes of some thousands of stars determined in this way have been announced, and are known as spectroscopic parallaxes. The underlying principle of the method may be summarized as follows: Stars may differ in mass, and stars of the same mass may differ in density; but, when the mass and density are given, no other important difference can occur, and the luminosity, surface temperature and pressure in the reversing layer should be uniquely determined; hence the spectrum should be determinate. Conversely, a sufficiently close examination of the spectrum (its position both in the Draper sequence and in the classification transverse to it) should fix the mass and density of the star, and hence its other physical properties, including luminosity. Ideally the deduction of luminosity might be made theoretically, but in any case the connection between luminosity and spectrum can be observed experimentally and formulated as an empirical law.

The Interstellar Gas .- In certain spectroscopic double stars the phenomenon of "stationary calcium lines" is observed. Whereas the other spectral lines shift to and fro as the star approaches and recedes in its orbit, the H and K lines of ionized calcium remain stationary. It is clear that somewhere between us and the star's photosphere there must be an absorbing cloud of calcium vapour which does not follow the star in its orbit. The phenomenon was first pointed out by Hartmann in 1904 for the star & Orionis. Later Miss Heger discovered that the D lines containing sodium also remain fixed in & Orionis. The same behaviour has now been observed in a large number of stars. In recent years, T. H. Dunham and W. S. Adams have found stationary lines of potassium, titanium, iron and neutral calcium, as well as of the molecules of CH and CN, in the spectra of a number of stars. The important question to decide is whether the cloud belongs to the double star or whether it is a continuous cloud filling interstellar space. J. S. Plaskett has shown that the latter alternative is correct; the motion of the calcium cloud is often different from that of the centre of mass of the star. After removing the solar motion the velocity of the cloud relative to the mean of the stars is found to be small. Just as there are lines in the solar spectrum which do not share in the sun's rotation and are accordingly to be attributed to absorption during the passage of the light through the earth's atmosphere, so we have stationary lines of elements which do not share in the orbital or individual motion of the star and are to be attributed to absorption in an interstellar "atmosphere." In the spectra of some stars the stationary lines are double or consist of three or four components, giving evidence of the absorption of the starlight by two or more interstellar clouds, which are in motion relatively to one another. The stationary lines are extremely sharp, which often enables them to be distinguished from the ordinary lines in the spectrum; this sure of the reversing layer, a complete classification of spectra sharpness is the consequence of the extremely low density of the

interstellar gas, which is so tenuous that the starlight must pass through a very great length of it to produce an absorption line of sufficient strength to be detected. The fixed lines appear most conspicuously in the spectra of the hottest stars because these stars are highly luminous and are consequently observed at a great distance; the cooler stars, moreover, have strong calcium and other metallic lines of their own, which mask the lines of the cloud. The absorption occurs along the whole track of the light, and though the absorption is not necessarily uniform along the track (as evidenced by double or multiple components) there is a strong correlation between the strength of the lines and the distance of the star

It is probable that many common elements, in addition to those It is produce that many common elements, in adultous or other which have been detected, are present in the interstellar gas; but the gas is so extremely rarefied that only the most abundant elements and compounds can be detected. Many elements must also evade discovery, even though they may be very abundant, because their atoms, when in their state of lowest energy as they must be in the atoms, when in their state of lowest energy as they must be in the interstellar gas, are indifferent to visible light. Thus, for instance, bydiogen has never been detected in interstellar space by its spectral lines, the detection of molecules of CH prove it to be present, and for other reasons it is known to outstrip by far all other elements in abundance.

In order to avoid a huge mass of the stellar system inconsistent with the observed velocities of the stars, it must be postulated that this interstellar cloud is of very low density. About one atom per cubic centimetre is the maximum that can be allowed. It is calculated that centimetre is the maximum that can be allowed. It is calculated that matter so diffuse as the woold take up a high temperature not much lower than the photospheric temperatures of the stars, although a shockite. The density is to small to give any appreciable scattering or absorption of light in pance other than the special line-absorption of calcular and sodium light. The drimming and reddeming of distant objects is caused by interstellar dust; a small quantity of dust can cause appreciable obscuration and the interstellar dust forms but a can cause appreciable obscuration and the interstellar dust forms but a small fraction of the total mass of the interstellar matter.

STAR APPLE (Chrysophyllum cainito), an evergreen tree of the family Sapotaceae (q.v.), called also cainito, native to tropical America and cultivated for its edible fruit. The pleasantly flavoured fruit, 2 to 4 in. across, is apple-shaped. In a crosssection of the unripe fruit the seed-bearing cells form a star.

STARAYA RUSSA, a town of the Russian S F.S R. in the Leningrad region, in 58° N., 31° 22′ E., on the river Polista, by means of which and Lake Ilmen it is brought into steamer communication with Leningrad. Pop. 21,511. Brine springs on the east of the town were used as a source for the supply of salt as late as 1865; afterward they were used only as mineral waters (temperature 51°-54° F.), having a great resemblance to those of Kreuznach in Germany. Some thousands of visitors were accustomed to resort to them every summer, and owing to this circumstance Staraya Russa was better built and better kept than any other town in the government of Novgorod. The inhabitants are supported chiefly by the summer visitors. There is a trade in rye, oats and flax. Staraya Russa belonged to the republic of Novgorod, and suffered in the wars between Russia, Lithuania and Livonia. It was afterwards annexed to Moscow.

STARA ZAGORA, the capital of a department of southern Bulgaria lying on the southern slope of the Karaja Dagh, 70 mi. N.W. of Adrianople, with which it is connected by railway. Population (1934), 29,857. The city is surrounded by vineyards. and has flour mills, breweries, brandy distilleries, copper foun-

dries and tanneries The production of silk and attar of roses is carried on in the district, which contains numerous mineral springs, and there is a trade in corn and wine It is the junction of the trans-Balkan and Burgas-Philippopolis railway lines It was destroyed during the Russo-Turkish War (1877-78) and rebuilt on modern lines During the rebuilding, important Thracian, Roman, Byzantine and Turkish antiquities were discovered

Stara Zagora, founded probably by the Thracians, was known to the Romans as Augusta Traiana, but afterward, to distinguish it from a Macedonian town of this name, it was named Beroe or Berrhoea By the Turks the name was changed in the 17th century to Eski-Zagia or Eski-Zaara, whence its Bulgarian name.

STARCH. This is perhaps the most widely distributed substance in the vegetable kingdom and occurs, often in great abundance, in almost every plant. Pure starch has the appearance of a white, glistening, friable powder, and possesses a harsh feel when rubbed between the fingers, it is tasteless, has no smell, is not soluble in cold water and undergoes no change when exposed to the air. When examined under the microscope it is found to consist of granules of definite shape, size and appearance. These show very wide variations, some being minute while others attain a comparatively large size, they are, nevertheless, quite characteristic of the plant from whence they are obtained, and the identification of any particular starch by comparison with those of known origin is a more or less simple matter. Granules or cells which are usually oval in shape are found to be composed of a series of concentric layers arranged around a nucleus or hilum which appears as a dark spot, the outer layers being the oldest in point of growth

Starch belongs to the group of carbohydrates in which are included the sugars, gums and cellulose, and is composed of the elements carbon, hydrogen and oxygen. Its constitution is very complex, but it is built up in the plant from two simple compounds, water and the carbon dioxide gas present in the atmosphere, through the agency of the green colouring matter, chlorophyll, under the activating influence of sunlight. The rôle of starch in plant economy is that of a reserve material, and as such it must be transferred from the leaves and other green parts of the plant, where it is formed, to more permanent quarters. To facilitate this migration it is broken down into sugars which dissolve in the cell juice, in this way passing through the cell walls of the plant finally to become reconverted into starch, either in the fruit or seeds, or in the bulbs and tubers as the case may be. It is thus rendered available as a source of sustenance for the young plant until it is sufficiently advanced to carry on the process of starch formation itself. Starch as it occurs in the granular packages visible under the microscope, is not present as simple molecules of the empirical formula (CaH10Os), but probably as sheaves or groups of molecules of varying density of packing, the individual molecules being associated together by secondary valence forces Starch is a highly organized or "associated" substance. When heated with water it forms a paste, the physical characteristics of the resulting paste being different for each type of starch Aside from the differences in these pastes due to the variety of staich grains, the properties are further modified by mechanical and chemical action. When starch is heated in plain water, it takes on water and hydrates. The granular packages first swell and then rupture to form a paste. The body and consistency of the pastes will vary greatly, depending on the severity and intensity of the cooking and agitating treatments. These modifications are due mainly to mechanical means-that is, merely tearing the granules without materially altering the chemical structure. In the presence of chemicals, however, particularly acids and enzymes, the molecule itself is degenerated, the products formed representing a breakdown of the original molecule. The type of starch degeneration product formed in the presence of these chemicals and the extent to which the original molecules are degenerated will depend on the nature of the chemical substance, concentration, temperature, etc. In this manner are made the thin boiling (low viscosity) starches, dextrins, syrups and sugars. This process is employed in the manufacture of corn or glucose syrups, used extensively in confectionery, and of glucose sugar used in brewing Hydrobytic degeneration is also effected by certain natural ferments or "enzymes" such as those in salva, pancreatic junc, malted grain (diastase)—all germinated seeds, and it is the latter agent which is employed in the fermentation industries brewing, distilling, etc—lonverting starch in the materials used into material capable of fermentation by vesa;

Development of starch in the growing plant already refered to, and the rebuilding of the soluble products fine the cellulous which constitutes the tissues, is caused out by ferments or enaymes elaborated by the plant itself, while a similar process goes on in the human system when starchy foods are eaten and converted into soluble sugars canable of assimilations.

Dry starch heated to upwards of 320° F is transformed into dextrin, a pale, yellowish powder soluble in water, known as British gum Dextrins of lighter colour are also made by spraying with acueous acids and heating to lower temperatures.

A very sensitive reaction of starch is the production of an intense blue coloration with a solution of aqueous iodine, a characteristic much used in its identification. The average starch content of the principal starch yielding plants, together with the temperatures at which the purified starch gelatinizes when heated with water, are, according to Lippmann, as in the following table.

	content %	temp F		content %	temp 0
Potato	18-20	145	Millet .	53-55	
Wheat	54-58	152	Peas	39-49	
Barley	40~46	145	Lentils	39-40	
Oats	35-38		Arrowroot	20-30	158
Rye Marze	44-46	131	Тарюса	25-40	156
Marze	55-65	145	Yams	25-35	
Rice	70-70	142	Sago		158

The storehouse, or starch-containing part of the plant, consists of a network of cells, within the walls of which the starch granules are closely packed together. The process of manufacture involves the rupturing of the enveloping cell walls and separation of the starch from the associated material by levization

Manufacture—The manufacture of starch from roots and tubers is usually carried on in the locality in which they are grown; that from potatoes on the continuent of Europe, principally in Germany, France and the Nethelands; arrownove, cassava and tapioca are prepared from the roots and tubers of the maranta and manioc plants in the Verle Indies and South America; sago is manufactured from the puth of the sago pain and also from the varies or sweet potatoes in the East Indies and Borneo. Cereals can be more readily transported and stored, so locality is a matter of convenence; thus rice is used as a raw material in England, France, Germany and Italy and other parts of Europe, while maize is used very extensively in North America, and in England, France and Germany. Wheat is not largely employed.

The purposes for which starch is manufactured can be classified under three heads: (a) Industrial. These netude sizing yarn and cloth in the textile industries; dressing cloth; thickening mordants and colous in calico pintules; the pieparation of British gums and destrim, confectioners' glucose or corn syrups, and sugars for use in the form of comflour, arrowroot, taploca, sago, etc., or in conjunction with other substances in the preparation of custard and blanc mange powders, sauces, cocoa, confectionery, etc. (c) Loundry, In pipe or crystal form and powders, both "thick" and "thick"

boiling" preparations.

The suitability of starches from various sources for these purposes depends on their cost, putily, the stiffness or viscosity of the paste they make with hot water and the size of the granules. Potato, maize, rice and wheat starches are those chiefly used for industrial purposes; rice, maize, are arroworo, cassava and sage for foodstuffs; and the small granuled starches, rice and maize, are used extensively in the laundry owing to the fact that the granules are required to enter the texture of the linen or cloth before becoming gelatinged by the hot iron.

The general principles for dealing with all types of roots and tubers are substantially the same, but of course vary in their elaboration and efficiency in different parts of the world, and they also only differ to some extent in detail when cereals are being treated. They are briefly as follows:—The tubers first go through

washing machines where earth, stones, sand and grit are removed; they then pass to a rasping machine where all the cells are completely ruptured. The resulting pulp is washed in a fine stream of water on fine-mesh brass seves, which separate the starch from expectable fibre, etc., the resulting milky starch luquor is run lato vats to separate fine sand and grit by settlement, through fine sik seves for further purification, and is finally allowed to run very slowly over long, shallow, wood troughs, runs or tables, where the pure starch settles out and the impuritues pass off at the ends with the water. The pure white starch is washed from the runs by a tof water and is pumped to either filter presses or hydro extractors, which remove all except about 40-45% of the water, leaving the starch in the form of a damo cake.

The cereals contain varying proportions of protein or gluten material associated with the starch, and special methods have to be employed in their prehimmary treatment. The protein contained in nce is found to be rendered soluble by very weak caustic sods solution, and advantage is taken of this in the production of starch from the raw material. Maize in addition to protein contains an oil-containing germ which it is necessary to remove. In this case the grain is first steeped for 2 to 4 days in warm water containing 1% of sulphur doxide, ground in burr stone mills, and the resulting diffuent mass diluted with water is passed through a long V-shaped tank where the sem floats and is skummed off.

Wheat contains gluten which forms an elastic paste with water and cannot be removed by levigation. The procedure carried out in this case is to reduce the grain to flour which is then made into a dough with water, divided into small pieces and placed in a semicircular silk or fine brass sieve where a travelling roller presses out the starch which is removed by a fine spray of water. The starch houor goes through a very similar purification process to that employed for maize, often being treated with dilute caustic soda solution to swell the gluten and assist its removal between the sieving processes. It is necessary to carry out the final drying process at very low temperatures to prevent the gelatinization of the starch granules. Several methods, similar in principle for starches from all sources, are in use in the large factories, and consist of either bringing the starch lumps or blocks in contact with a continuous current of warm air, or evaporating off the excess of mosture in a vacuum chamber. For producing the starch in the form of powder or flour the moist lumps are either placed on an endless band running backwards and forwards in an enclosed chamber through which warm air is drawn, or they are placed on trays mounted on a trolley and passed through a tunnel in contact with warm air. In the tropics drying is usually carried out in the open air.

out in the open air.

Prism or crystal starch is prepared from maize or rice starch for laundry purposes, and is produced by forming the damp starch into blocks by draming off the water from the starch liquor in boxes with perforated bottoms covered with filtering cloths; the blocks are cut into two or more sections which are partly dried in a warm chamber, the yellowish brown crust which forms on the outside is scraped off, and the blocks wraped in paper, returned to the drying chamber and dried very slowly. Under this treatment the blocks break up into irregularly shaped prisms technically termed "crystals." Pearl taploca is made by heating the slightly moist starch from manioc in a steam-heated copper pan with constant stirring, some of the cells becoming gelatinized and adhering together in small, irregular masses. Further drying fol-

lows and the crude lumps are passed through rollers and graded.

Granulated or pearl sago is prepared by drying the starch in
such a way that it forms a plastic dough in which a portion of the
granules have become gelatinized, forcing this through sieves, and
drying the resulting granules in the air.

STAR CHAMBER, the name of an apartment in the royal palace of Westminister, a meeting place of the king's councillors, delived for mostars fashioned on the roof, perhaps, of the hall By derivation, later on, the name of councillors and judges sitting there as a court

In 1998 repairs of the "Sterred Chambre" are mentioned. In 1453 a meeting "in concilio nostro" (in our council) was held "in the Sterred Chambre." In 1542 a law provided pumshment for those convicted "in the Starr Chambre at Westmynster before the Kinges most honorable Counsell."

the Aniges miss isonomic Collises.

In the modic ages judicial functions were exercised by the king of England and his council. The corown never parted with superne jurisdiction. The council shared it, and also did the superne jurisdiction is the council shared it, and also did the property of the council shared it. And also which had evolved from the even egis. The king's council in star chamber and elsewhere, was reinfracted by judges of the royal courts and by various others. From time to time partament defined and approved this judicial work. In 145° a statute (3 Henry VIII, e. 1)—for a long time mistakenly supposed to have established the court of star chamber—samed a commission of seven principal councillors and two of the judges, to try offenders too great to be dealt with by ordinary courts.

In the 16th century councillors, judges, persons specially summoned, additional "counsel," and great lords sometimes attending, acted either as a council or a court in star chamber, records being kept by clerks

Councillors and judges sitting in star chamber were more and more thought of as the court of star chamber. They dispensed much justice and heard many cases often by desire of the parties concerned. Hearings were public; there was no jury, torture was sometimes used to get confession. Generally speaking, it was a court of crumal jurisdiction, particularly in respect of volation of royal proclamations; but "all offences may be here examined and punished if the king will." Sentence of death was never pronounced. The court punished with imprisonment and with fine, even with mutilation.

Under Eknabeth attendance at star chamber approximated to that at prity council, with reinforcement of pudges, so that the two bodies were differentiated in function rather than in personnel Under James I and Chanles I star chamber continued as an active, important court, largely respected and liked. As Purtan and parliamentary opposition developed, however, it incurred odum from severe penalties, and the reputation then affixed by enemies has since persisted In fagit it was sobbled by an act of the long parliament (46 Charles I, c. 10) and the judicial power of the councillors in privy council was abridged. (E. R. T.)

STAR CLUSTER. There are regions here and there in the sky where the stars are much more richly strewn than usual. Some of these are clusters, where hundreds or thousands of stars are seen connectinated together in a small field of view, providing show-objects—beauty spots of the celestial landscape. Not only are they impressive to observe, but they have led to remarkable advances in our knowledge. The measurement of the extent of the visible universe and an indication of its organization, information on the existence and distribution of dark diffuse matter in intestellar space are among the contributions to subromory that have been made chiefly through the study of star clusters. The researches have been descriptive, astrometric, photometric, spectroscopic, statistical, mathematical and speculative—often complicated, and more often very tedious.

Discovery and Catalogues of Star Clusters.—Among the few clusters observable with the naked eye the Pleades group is undoubtedly the best known. It attracted the attention of primitive men and became the subject of numerous myths and legends. The Hyndes group surrounding the bright star Aldebaran and the dim star group in the constellation of Coma Berenices were also noticed in ancient times. About a score of the brighter clusters such as the doubtle cluster in Persesua are visible to a keen eye as

diffuse unresolved nebulous spots of light.

The true nature of star clusters as a class of celestial objects was, however, not recognized until after the invention of the telescope and many of the most striking clusters were discovered by the early telescope observes during the 17th and 18th centures A catalogue of nebulae and clusters published in 1754 by the repend astronmer Charles Messer listed 57 sar clusters A systematic search of the whole heavens undertaken by William Herschel at that period and continued by his son John Herschel led to many new discoveries of clusters to which relatively few have been added

Star clusters are in general designated by their number in the catalogue of Messier or in the New General Catalogue (NGC) of John L E Dreyer.

Galactic Star Clusters and Globular Star Clusters.—The amazing varrety in appearance of star clusterings led Herschel to divide them into classes. The principal division into loose or open clusters and densely crowded globular clusters was later recognized to be fundamental, manly through the researches of Harlow Shapley. The two kinds of clusters differ not only in constitution but also in their cosmic relation to our stellar system

The open clusters are easily resolvable, wared in shape and richness and the star population ranges from a few dozen to a few thousand. They are scattered all along the Milky Way, often appearing like nuclei of condensation in the rich star clouds. On account of their close relation to the Milky Way they are now more commonly designated as galactic star clusters. About 350 objects of this class are known.

The globular clusters, about 100 in number, are characterized by their uncommon nchmess in stats (several thousand to several hundred thousand), by the remarkable regularity of structure and nearly globular symmetry. Their stars are faint and generally show a high degree of concentration toward the centre where they often appear so closely crowded that the photographic plate is unable to resolve them.

#### GALACTIC STAR CLUSTERS

Definition .- In the scientific sense of the term, a cluster is a local group of astronomical bodies held together by their mutual gravitational attraction. Its members must have had a common origin and are thus physically related to each other. Wide binary stars, multiple stars, typical star clusters and star clouds are examples of such gravitational organization. Galactic clusters are generally distinguished from star clouds by their subordinate size and greater unity of structure. Between multiple stars and the poorer star clusters, however, there seems to be no real division. The line drawn by the astronomer is merely one of convenience dictated by methods of observation and description. Among star clusters those systems are to be included which contain a sufficient number of stars (not less than about 20) to be described statistically. A star cluster can then be characterized by such data as angular diameter, degree of concentration toward its centre, symmetry, distribution of stars according to brightness, richness in stars, etc. Some of the poorer clusters like N.G.C. 957 consist of a mere sprinkling of faint stars and it is often difficult to decide which of these should be included in a cluster catalogue

Constitution.—To obtain a true idea of a cluster as a system of stars in space three difficulties have to be overcome:

I. When a cluster is examined in a telescope or on a photograph, it appears superposed on the general star field of the sky, and it must be expected that some of the stars seem within the outline of the cluster are in reality located far behind it or in front of it. To study the constitution of the system, it is necessary to identify its individual members by their motion, spectral class or colour or to allow for the probable number of background and foreground stars statistically.

2 The observation of a cluster furnishes a two-dimensional picture, the arrangement of stars in depth escapes our scrutiny. For systems with spherical symmetry the statistical star distribution in space can be calculated from the apparent distribution in the projection.

3. The most difficult problem is to measure the distance of a

cluster from the observer. This knowledge is needed to find the linear dimensions from the observed angular hameler, to gain an idea of the distances separating the individual stars from each other, of the gravitational forces acting between them and to calculate from the apparent brightness of its stars their true lumnosity as compared with the sun

A rich galactic star cluster like the Pleades consists of 300 to 500 stars spread through a sphere about 50 light-years in diameter. The stars, particularly the brighter ones tend to congregate near the centre and thin out very gradually toward the periphety, so gradually that the extreme limit of the system is difficult to ascertain. On mere examination of a photograph only the central core of the cluster (about one-third of the limiting diameter) attracts the attention of the observer, the thinly scattered members of the outer parts are lost among the backeryound stars.

Even in the concentrated central part of a cluster each star is on the average separated from its merset neighbour by the enormous distance of 1½ light years. If we attempted to make a model of a galactic cluster with punheads as stars, the punheads would have to be placed 4 to 5 mi apart; a few hundred pinheads scattered through a sphere 150 m in diameter. Nevertheless, the space density of stars, at the centre of a rich cluster, is more than 100 times greater than in the vicinity of the solar system.

The limiting diameters of galactic clusters vary between 15 and 5 light years. The richer systems are larger than the poorer ones; their average star density therefore shows little variation, but in some the stars are more concentrated toward the centre than in others.

Spectral Classes and Luminosities of Cluster Stars.—Most clusters of the galactic class are so well resolved that spectroscopic and photometric observations of its individual stars can be made The distribution of stars according to spectral class and magnitude or luminosity reveals significant differences between clusters In some, like the Pleiades, all members belong to the Main Sequence, the brightest stars are of spectral classes O. B. or A (high temperature); with decreasing brightness the spectral class advances gradually through F and G to the K dwarfs. In other clusters, like the Hyades, we find in addition to Main Sequence stars also some giant stars of great luminosity and low temperature, and in a few the low temperature giant stars are very numerous The latter clusters seem to form a transition toward globular clusters A system for classifying galactic star clusters according to the magnitude-spectral class distribution of its members has been developed by Robert J. Trumpler.

Compared with the star population in the vicinity of the sun, galactic clusters are relatively rich in stars of high luminosity or candle power. Often the brightest stars in a cluster are several thousand times more luminous than our sun, in fact some of the most luminous stars known are involved in star clusters. Since high luminosity is associated with great mass the presence of such stars is important for the stability of the group. The gravitational attraction of these massive stars which are usually near the centre contributes much toward keeping the cluster together and preventing its stars from escaping into space. According to Bart J. Bok, a cluster must have an average mass density of more than 2,7 solar masses per 1,000 cubic light-years to resist disruption by the rotational motion of the stellar system.

It is not unusual to find that a member of a star cluster is itself.

It is not unusual to find that a member of a star cluster is itself.

It is not unusual to find that a member of a star cluster in itself as a star cluster unusual around double star Vid appetraction with periodic change of brightness, on the other hand, are very rare. It should also be mentioned that many clusters of the galactic class are involved in faintly luminous nebulosity.

alonly unmois decionestly.

Common Medicine of Cluster Stars.—That the individual state in the same motion through space has best and the same motion through space has best and the same motion from the calest in space of a set of the radial velocities (motions in the line of sight measured spectroscopically). For large and near clusters, like the Hyades, the paths of the stars appear to converge to a common point (or diverge from one). This convergence is obviously a matter of perspective. When the convergence is obviously a matter of perspective. When

vergent point is accurately determined and the radial velocities of some stars are measured, the distance of the cluster and the velocity of its motion through space can be deduced

For the smaller and more distant clusters the motions of the stars appear practically parallel and equal. If the proper motions are sufficiently accurate, however, their study makes it possible to distinguish the physical members from the background airs.

This phenomenon of common motion should be interpreted in the sense that the velocity with which the whole cluster travels through the stellar system is much larger than the internal motions of its stars with respect to each other Under the gravitational attraction of all the other cluster stars each member will describe some kind of orbit around the common centre of gravity, but the velocities of these orbital motions are quite small and for their successful study swerral centuries will be required.

Common space motion is sometimes found among stars widely spread over the celestal sphere without any noticeable clustering. The Unsa Major group is an example of such a case. Five of the seven conspicuous stars of the Big Dipper as well as Sirius and other bright stars are ablke in spectral class and move in parallel paths through space. Such groups are called moving clusters They are probably remnants of star clusters in the stage of dissolution

Distances.—Most of the galactic star clusters are so far away that their distances cannot be found by measurement of parallax or by the convergence of the proper motions; more or less induced methods must be resorted to.

The spectroscopic-photometric method takes advantage of the fact that for stars of the Main Sequence (or the Giant Branch) the luminosity is closely related to the spectral class, a relation which has been well established by studies of the nearer stars For any cluster stars whose spectra have been classified this relation will furnish a fair estimate of their luminosity. A comparison of the luminosity with the observed apparent brightness leads to the distance on the assumption that the apparent brightness of a star decreases with the square of the distance. This assumption, however, holds true only if the space through which the light travels is perfectly transparent. In the Milky Way, where most galactic clusters are situated, there is evidence of the presence of dark matter, cosmic dust scattered through interstellar space and the absorption of light caused by this matter must be taken into account for the more distant clusters.

Another method of distance determination is based on the assumption that star clusters of similar constitution have the same linear dimensions. For each homogeneous group of clusters the distances are then inversely proportional to the measured angular diameters. The diameter method must be calibrated by means of distances determined by the other method; it is then applicable to those objects which are too faint for spectroscopic observations. This method has also been valuable for testing the distance scale of the photometric method and for determining the effect of absorption of light in space.

The distances of the known galactic clusters as determined by Trumpler range from 120 to 20,000 light-years and 80% of these are between 2,000 and 12,000 light-years.

Space Distribution and Motion .- When the arrangement in space is considered (see fig. 1), the galactic clusters are found to nestle close to the plane of the Galaxy and to scatter through a disk about 35,000 light-years in diameter. This disk has the sun near its centre but has a very eccentric position compared with the outline of the stellar system. The whole situation suggests that the observed extent of these clusters is conditioned by the observer's location and his range of vision. Our list of galactic clusters is evidently incomplete. The light absorbing interstellar material forming a layer along the galactic plane spreads like a haze throughout the region occupied by galactic star clusters and is responsible for dimming or obscuring the more distant ones. Even a rich brilliant star group like the Pleiades when seen at a distance of 20,000 light-years would be so dim that it would hardly be noticed among the innumerable faint Milky Way stars and would have escaped discovery by the survey methods of the past. Photographs utilizing red light which has a greater penetrating power, however, may reveal many additional star clusters of this class at greater distances

Radial velocity measures are available for many galactic clusters, distant as well as near ones. Their analysis shows these star groups to follow closely the rotational motion of our galaxy as represented by the Ooit-Lindblad theory Each cluster revolves

50 000 LIGHT YEARS

FIG. 1.—SPACE DISTRIBUTION OF GALACTIC AND GLOBULAR STAR CLUSTERS

The figure literates how our stellar system would appear to an outside observer. The official fine indicates it he procedule outline of the flattened because of the flattened because where the flattened because where the procedule of our our in shown by a core. The 550 known pasterio their observations are seathered among the stars through the region marked by inhaling. The small critical represent the hondred globular cluster which surround the star prevents.

around the centre of the galaxy in an orbit which is nearly circular and parallel to the galactic plane.

By the kind of stars they contain, by their space distribution and motion galactic star clusters are intimately related to the Milky Way star clouds. Like these they probably had their origin and evolution in the highly flattened outer part of our stellar system which by analogy with other galaxies is assumed to have a spiral structure.

#### GLOBULAR STAR CLUSTERS

Distribution and Classification—In their distribution over the sky the jobular clusters are most pecular, they are nearly all found in one hemisphere which is centred in the such Milky Way region of Sagittarius. On both sides of the Milky Way they extend to high galactic altitudes. As we approach the low galactic latitudes, however, they become more numerous, up to the very edges of the stream of Milky Way star clouds. But their number suddenly falls of near the central line of the Milky Way, so that only two or three are found along a central belt seven or eight degrees in width. It is just within this region devoid of globular clusters, that the galactur clusters and rich star clouds are most numerous.

There is a general similarity among globular clusters except for considerable variations in star content and marked differences in compactness. The latter has been made the basis of a classification by Shapley and Miss H. B. Sawyer. The roo globular clusters are divided into 12 approximately equal classes, Class I representing the highest concentration of stars toward the centre, and Class XII the least.

Messier 13 is a rich cluster with considerable central concen-

tration (Class V), while Messier 55 is an example of a loose globular cluster (Class XI).

Many of the objects with little concentration are also relatively poor in stars. They are called giant-poor and are by some considered as a special subdivision of globular clusters.

Size and Structure.—The angular diameters of globular clusters are difficult to measure because of the ill-defined intist Moreover, these clusters appear to grow in size when the exposure time of the photograph is increased. If the distances are known, the linear diameters can be calculated; they vary from about 50 to 50 plgh-vears, not counting the most outlying members. Clusters of the globular class are thus on the average 3 to 4 times larger in diameter than those of the galactic class. Systems very rich in stars are generally larger in size and it has been suggested that the average space density of stars tends to be the same in all globular clusters, but is considerably higher than in galactic clusters.

A typical globular cluster is slightly flattened as though by rotation. This flattening reveals itself through the elliptical form of the projected image and the latter has been established in many cases by detailed counting of stars. It is not possible, however, to evaluate separately both the true flattening of a cluster and the inclination of its equatorial plane to the line of sight The most we can say is that some globular clusters have equatorial diameters at least 40% greater than their polar diameters in no cases do they appear to attain the high degree of flattening observed in spiral nebulae (see NEBULA) or in the Milky Way system itself.

Much work has been devoted to studies of the statistical laws governing the star distribution in globular systems. Assuming radial symmetry the number of stars per unit volume, N, at distance p, from the cluster centre can be calculated from star counts in the projected image, which gives the number of stars per unit area, n, at the projected disance, r, from the centre. The formula (Edward C Pickering, H. von Zepel) is

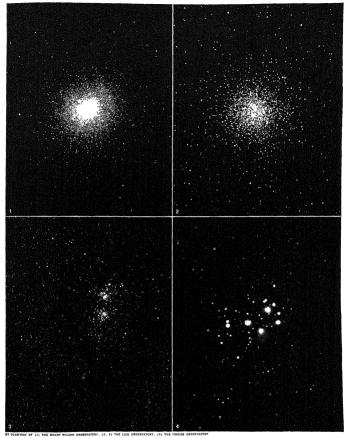

$$N(\rho) = \frac{1}{\pi} \int_{\rho}^{R} \sqrt{(r^2 - \rho^2)} \frac{d}{dr} \left( \frac{1}{r} \frac{dn}{dr} \right) dr$$

Analogies with the kinetic theory of gases have encouraged some of these researches; but no completely satisfactory representation of the observations has been found. It must, however, be realized that the available star counts deal only with the few hundreds or few thousands of the most luminous stars and that they are affected by errors caused by photographic and instrumental effects.

In general, the frequency of giant stars, except near the centre, is (roughly) inversely proportional to the fourth power of the distance from the centre for most of the typical globular clusters Colours and Variable Stars.-Spectroscopic observations of individual stars in globular clusters are very difficult; but colour indices have been determined in several systems. The star distribution according to colour and brightness in globular clusters is undoubtedly different from that predominating in galactic clusters, but its interpretation is still somewhat uncertain. The most luminous stars seem to be red supergiant stars, the fainter ones appear to belong to the normal giants. Remarkable is the absence of Main Sequence stars of high luminosity which are an outstanding feature of most galactic clusters. Dwarf stars of the sun's light and diameter are unattainable with our present telescopic power when at the distance of even the nearer globular clusters.

The presence of great numbers of variable stars in globular clusters was first brought to attention by the work of Solomon I. Bailey at the Harvard observatory. In some systems one star out of six among the giant stars proves to have a periodic variation in brightness, whereas in other clusters of practically the same appearance no variable stars are found.

The overwhelming majority of the several hundred variable stars discovered in globular clusters have periods of less than a day and belong to the class now designated as cluster type variables. They form a subdivision of the Cepheid variables and their light variation is thought to be due to pulsation—that is, periodic

EXAMPLES OF GLOBULAR AND GALACTIC STAR CLUSTERS

- 1. Messier 33 in Hercules, a rich globular cluster with considerable
  2. Messier 55 in Sagitatrius, a loose globular cluster

  2. The Flat of the sagitatrius and the sa

expansion and contraction of the stars.

A few Cepheid variables of periods longer than one day, and a few irregular variables have also been found among the stars of these clusters.

Distances.—The relation between apparent brightness and period for Cephetes in the Small Magellance (Ione), found by Miss Hennetta Leavutt, was generaised by Shapley with the said of galactic Cephetes and the variables of the globular clusters. The period-luminosity curve, which selates the absolute magnitude (untrunsic luminosity) of the Cepheid variable to the logarithm of its period, was thus derived. The zero point of the curve was fixed with the aid of the neares galactic Cepheid variables, for which the distances and absolute magnitudes were determined from studies of their motions

The period-luminosity curve permits the determination of the intrinsic luminosity and therefore of the distance of any Cepheld variable when the period of its variation and its apparent brightness are measured. With its use the distances of all the globular clusters, or other stellar systems, which contain Cepheid variables are simply derived. When the distances of clusters containing Cepheids have been obtained, the distances can be inferred also for the clusters devoid of variables, because of the apparently inherent similarity of all globular systems in linear size, total luminosity and in the real brightness of their most luminosity and in the real brightness of their most luminosity and in the real brightness of their most luminosity and indicators of divitance.

The effect of interstellar light absorption which must be allowed for in the distance determination is relatively small for missing globular clusters because they are situated far from the galactic plane, outside of the absorbing layer. Our list of roog joint clusters should thus be nearly complete except for those in the central belt of the Milky Way which are heavily obscured.

Though subject to considerable uncertainties, the distances of the globular clusters range from 12,000 to more than 100,000 night-years. The evaluation of these tremendous distances with a reasonable degree of reliability constitutes one of the triumphs of modern astronomical investigation.

Cosmic Role of Giobular Clusters.—As shown in fig. 1, the globular star clusters are arranged in a fairly symmetrical group surrounding our stellar system. The centre of this group is at a distance of 35,000 light-years from the sun and in 1795 Shapley suggested that it represents also the centre of the stellar system. This hypothesis has now been generally accepted. The study of globular clusters has thus given the first important clue to the eccentric location of the sun and the extent of our galaxy of which larne parts are hidden from our view by absorption of light.

The proper motions of globular clusters are as yet practically unattainable because of their great distances. The radial velocities of many of these systems, however, have been measured by feeding the total light of the numerous crowded stars near the centre of each object into the spectrograph. The results obtained by Vesto M Shipher at the Lowell observatory and more recently by Nicholas U. Mayall at the Lick observatory show that globular clusters move through space with velocities of 100 to 400 km p.sec., velocities much larger than those of most classes of stars, the centre of gravity of the globular clusters is taken to be at rest with respect to our stellar system, the sun appears to be moving at the rate of 300 km, sec. and this probably represents the speed of the sum's orbital motion around the centre of our galaxy.

The observed radial velocities as well as the spherical grouping of the globular clusters seems to indicate that they do not take part in the rapid rotational motion of the stellar system. Their orbits with respect to the centre of the galaxy are probably much elongated and in planes of varying orientations.

The globular clusters must have separated from the main body of our galaxy at an early period of its evolution and now surround it as satellite systems.

STARFISH. This name covers three classes of the echinoderms, sea stars or Asteroidea, britile stars or Ophiurodea, and feather stars or unstalked Chinoidea. (See ECHINOBERMA, figs 1, 2 and 4) The Asteroidea and Ophiuroidea are free-moving and live mouth downward, the feather stars, though they can swin or crawl, live most of the time attached to some object by their challenges much work that stars of CSE ECHINOPERMY.

dorsal cirri, mouth upward or outward. (See ECHINODERMA.)
The Sea Stars, to which the name "starfish" is usually restricted, include many different forms of which the most familiar are Asterias of the North Atlantic coasts and its relatives in the North Pacific. These animals consist of a central body radiating out into five tapering arms. The flattened upper surface is covered with a leathery skin in which are small lobed plates of carbonate of hme, many bearing prickles, together forming a jointed reticulate skeleton. Multitudes of small pincerlike pedicellanae are present (Cf. SEA-URCHIN.) For further details of structure see ECHINODERMA. A sea star of this type can crawl over any surface and can squeeze its supple body through incredibly narrow crevices. The rate of progress is about 6 in. a minute. The common sea star of the Atlantic coast of North America south of Cape Cod (Asterias forbesz) is very destructive to mussels and oysters, which form its favourite food. No less than 42,000 bu. have been removed from the oyster beds of Connecticut in a single year. They had damaged the beds to the extent of \$631.-500. In attacking oysters and similar bivalves the sea star fixes the suckers of one or two arms to one valve, and those of the opposite arms to the other. It then begins to straighten out its rays. The oyster can withstand a strong sudden pull, but not a continued pull, and eventually it opens its shell. The sea star then extrudes its stomach through its mouth, digests the ovster, and after the meal is fimshed withdraws its stomach Sea stars begin to eat voraciously when very young. One less than \( \frac{3}{4} \) in. across ate over 50 young clams of half that length in six days. A sea star may become sexually mature in less than a year, then producing many thousands of young.

These familias sea stars, however, are scarcely representative of the group as a whole. Sea stars vary in shape from sharply stellate with long tapering rays, or pentagonal with the angles of the pentagon produced into slender spikelike arms, to pentagonal or almost circular; but most of them are stellate. The great majority have normally five rays, but some have six and a number have more, in one type (Heliaster) from 20 to 44. In size they vary from ½ in. to more than 3 ft. across. There are about 1,500 known kinds distributed in 300 genera. Most of them are predacious, feeding on molluscs, barnacles, worms, crustaceans and other smaller creatures which they take into their stomachs, but many are scavengers feeding on detritus or swallowing mud and digesting out of it the organic matter. Most commonly seen of the exotic sea stars is a large one more than a foot across, common in tropical American waters, in shape a low pyramid with a stellate base (Oreaster), which is widely sold as a curio. Related species, smaller, more solid and with large bony tubercles, are also popular with curio dealers; these are from the Pacific and Indian oceans. The cushion stars, also from the Indo-Pacific region, are pentagonal to circular, 6 to 8 in. across, greatly swollen with broadly rounded edges, and look like small cushions. When young they are pentagonal and flat with a border of large plates. Along the sandy or muddy coasts of all warmer seas live two types of sea stars which, though common, are usually unfamiliar. One of these (Astropecten) is regularly star-shaped with stiff arms bordered with large plates. It usually lives just beneath the surface of the sand. The other (Luidia) has five or more broad, flat and brittle sharp-edged arms. It is said sometimes to swim by means of the podia. In these, as in many other kinds, the podia have no crustaceans

The brittle stars or Ophiuroidea ("snake-tails") differ from sea stars in having long and slender arms which are quite distinct from the usually pentagonal or circular body. The digestive and genital organs are wholly within the body, except in a few cases where the latter extend into the arm bases. There is no vent and pedicellariae are never present (See ECHINODERMA, fig 2) There are about 1,500 known kinds arranged in 200 genera In most of them the arms are moved chiefly sideways, though they may coil vertically at the tip. The body varies between 3 and 57 mm in diameter. The arms are usually long, flexible and brittle, but may be rigid and tough. The common shore-living forms all belong to this section They are the most active of all echinoderms They live among seaweeds or eelgrass, in chinks and crevices of rocks or corals, buried in mud, or lying on the sea bottom in deep water. Some are symbiotic or semiparasitic in sponges or on various coelenterates, feather stars or sea urchins. In the tronics many are brilliantly coloured. In another type the arms, which may be more than two feet long, coil vertically These are all semiparasitic on coelenterates and live in deep water To these are related the basket stars or "sea spiders" with their manybranched arms, most of which live clinging to coelenterates. Several brittle stars are hermaphroditic, some live in pairs, male and female, and some brood their young Many brittle stars are important as tood for fishes, in the North Atlantic particularly cod and haddock

The feather stars (unstalked Crinoidea) are distinguished as Comatulida ("hair stars") from various other crinoids that at earlier periods of the world's history lost the stem. (See Echino-DERMA, fig 4) The stem is not really absent, but is reduced to a knob from which arise numerous jointed appendages (cirri) by which the animal clings to some support. From the small body extend five arms (in two genera ten) which may remain undivided, but most commonly fork near the base or branch several or many times. The arms are fringed with slender branches (pinnules) giving a feathery appearance. Though usually sedentary, feather stars can crawl about and some can swim. There are about 600 kinds arranged in 140 genera. They occur from the shore line down to about 18.045 ft, and are most diversified in the Indo-Padific region, most abundant in the north

STARGARD (Polish Starogród) a town of the former Prussian province of Pomerania, Ger., and after 1945 in Szczecin province in northwestern Poland, on the left bank of the navigable Ihna, 20 mi, E, of Szczecin on the railway to Danzig and at the junction of lines to Posen, Schneidemuhl and Cüstrin. Pop. (1939) 40,334; (1946) 9,733 Stargard, mentioned as having been destroyed by the Poles in 1120, received civic rights in 1229 and became the capital of eastern Pomerania. As a Hanseatic town it enjoyed considerable commercial prosperity, but it had also to undergo siege and capture in the middle ages and during the Thirty Years' War. It suffered heavy damage in World War II,

STARK, JAMES (1794-1859), British painter, was born in Norwich on Nov. 19, 1794, and at the age of 17 was articled to John Crome for three years. He died in London on March 24. 1850. Between 1831 and 1859 most of his pictures were shown at the Royal academy. He undertook in 1827 the publication of a work on The Scenery of the Rivers of Norfolk, which was completed seven years later; the illustrations he prepared for it have topographical and artistic interest. His painting "The Valley of the Yare" was acquired by the National Gallery of British Art.

STARK, JOHANNÉS (1874-STARK, JOHANNES (1874- ), German physicist, was born April 15, 1874, at Schickenhof in Bavaria and studied at the University of Munich. In 1900 he became an assistant at the University of Göttingen. He went as professor in 1907 to the Technische Hochschule at Aix-la-Chapelle, in 1917 to Greifswald and in 1920 to Würzburg; he retired in 1922. Stark devoted him-

suckers, ending in a conical point. Sea stars are eaten by gulls, self principally to the study of the modern theory of radiation crows, ravens, foxes and various fishes. Their chiefs parasites are and the atomic theory. He discovered the Doppler effect in parallel rays, for which the Vienna academy awarded him the Baumgartner prize. Later he discovered the Stark effect, named after him, and in 1919 was awarded the Nobel prize for physics He wrote numerous essays on physical problems, including the Prinzipien der Atomdynamik, in three parts (1910-15), Die elektrischen Quanten, Die elektrische Strahlung, Die Elektrizität in Gasen (1002) and Atomstruktur and Atombindang (1028) Stark was the founder of the Jahrbuch der Radsoaktsvitat und Elektronik (1904), which he edited until 1919, and president of the Reich Physical-Technical institute and German Research association,

1933-39. STARK, JOHN (1728-1822), U.S. soldier, was born at Nutfield, now Londonderry, NH, on Aug 28, 1728 During the Seven Years' War he served under Robert Rogers, first as a heutenant and later as a captain At the beginning of the Revolutionary War he raised a regiment and as colonel did good service in the battle of Bunker hill, the Canadian expedition and Washington's New Jersey campaign in the winter of 1776-77 In March 1777 he resigned his commission. Later in the year he was placed in command, with the rank of brigadier general of militia, of a force of militiamen, with whom on Aug 16 near Bennington. Vt , he defeated two detachments of Burgoyne's army. For this victory, which did much to bring about the capitulation of General Burgoyne, Stark received a commission as brigadier general in the continental army (Oct. 4, 1777) He took part in the operations about Saratoga, and for a short time was commander of the northern department. In Sept 1783 he was breveted major general He died at Manchester, N.H., on May 8, 1822

See Memoir and Official Correspondence of General John Stark (1860) by his grandson Caleb Stark

STARK EFFECT is the splitting of spectral lines observed when the radiating atoms, ions or molecules are subjected to a strong electric field. Soon after P. Zeeman discovered the magnetic splitting of spectral lines the electric analogue of the Zeeman effect (q.v) was sought by many physicists but success came first to Johannes Stark (q,v) in 1913. The earlier experiments failed because a strong electric field could not be maintained in conventional spectroscopic light sources (see Spectroscopy) because of the high electrical conductivity of luminous gases or vapours Stark observed the hydrogen spectrum emitted just behind the perforated cathode in a canal ray tube By placing a second charged electrode parallel and close to this cathode he was able to produce a strong electric field in a space of a few millimetres. At low gas pressure the mean free path of the atoms was much greater than the distance between the plates so that few conducting ions could be produced by collisions In an electric field of the order of 100,000 v per centimetre Stark observed, with a spectroscope pointing across the field, that the Balmer lines of hydrogen were split into a number of symmetrically spaced components, some of which were linearly polarized parallel to the lines of force, the remainder being polarized perpendicular to the direction of the field This transverse Stark effect resembles in some respects the transverse Zeeman effect, except that the separations (in wave numbers per volt in the first case, per oersted in the second) are larger, the number of Stark levels increases with election-shell number (s.e, principal quantum number) and the intensity distribution among the components is different. A satisfactory explanation of the Stark effect in hydrogen, given in 1916 independently by K Schwarzschild and by P Epstein, was a great triumph for quantum mechanics (q.v) since classical electromagnetic theory could not account for it

The Stark effect was also observed in the spectra of metals by employing special (LoSurdo) tubes containing a cathode of the metal under investigation, and viewing the light emitted near the cathode where a large potential gradient exists. In general, the electric splitting in spectra of metals is small compared with that in hydrogen, and unlike the Zeeman effect, which is symmetrical in spacing and intensity distribution of components, the Stark effect is usually only a displacement of unresolved components toward greater or smaller wave lengths. This effect does not depend in a simple way on the nature of the combining atomicenergy levels and for this reason the Stark effect in comparison with the Zeeman effect has little practical value in the analysis of complex spectra or of atomic structure.

STARLING, ERNEST HENRY, PRS (1866–1927), English physiologist, eldest son of H H Starling, was born in London,
April 77, 1866 Educated at King's College school, he entered
Guy's hospital in 1882 and graduated M D in 1890 In the same
year he was appointed lectured in physiology at Guy's In 1900
he became Jodrell professor of physiology at Guy's In 1900
he became Jodrell professor of physiology at University college,
London, where he continued to work throughout his life, although
in 1922 he retired from the Jodrell chair and was appointed Foulerton research rotofessor of the Royal society

Starling was one of the foremost physiologists of his age The subjects for investigation which particularly attracted him were those physiological processes which seemed capable of interpretation in terms of chemistry and physics. The conditions determining transudation from the vessels and lymph flow occupied his attention for several years, and he showed that the hydrostatic and osmotic pressures within the vessels supplied the balance of force necessary to explain the hitherto perplexing experimental facts. His researches on the movements of the intestines, in conjunction with Sir William Bayliss (q v ), demonstrated the neuromuscular mechanisms involved and reduced the previous chaos to order, Their discovery of "secretin" not only laid bare the way in which the secretion of the pancreas was called forth and adjusted but also stimulated further research on the chemical integration of the body functions By ingenious methods of experimentation he was successful in maintaining the mammalian kidney, isolated from all connection with the body, in a state of functional activity, thereby bringing to light new and fundamental facts concerning renal secretion Starling's most important researches, however, were those dealing with the heart and circulation Together with many other important discoveries on the physiology of the circulation, he demonstrated the mechanism by which the heart is able to increase automatically the energy of each contraction in proportion to the mechanical demand made upon it and, apart from the nervous system, to adapt its work in accordance with the needs of the body. Probably no physiologist had so greatly advanced knowledge of the heart's action since the discovery of the circulation by William Harvey.

During World War I Starling was dilector of research at the John Mary Medical Corps college and engaged in devising defensive methods against poison gas Subsequently, 1917-19, Starling was chairman of the Royal society Food committee, scientific adviser to the ministry of food and British scientific dele-

gate on the Inter-Allied Food commission.

STARLING, the name for birds of the passetine family Sturndac, which contains about 103 species. The normal range of the family is Africa, Europe and Asia, to Australan, with most species in the tropics. Certain species have been introduced into vanous other parts of the world such as Madagasca, Hawaii and North America, in which last area the common starling of Europe, Sturnus sudgess, has become common over a wide area.

Dark plumage, iddescent to the point of brilliance, characterizes many startings, but duller birds exist and one species is mostly white. Bare, coloured areas of skin, or wattles, decorate the heads of some. Certain species of the tropical forest are mostly arboral and eat frunt; others of open country walk about on the ground and eat finests. Several species are familiar birds, coming about houses and gardens where they may cause annoyance by usurping the nesting sites of other birds.

Gregariousness is a common trait. The birds may feed or roost in large flocks, and some nest in colonies. The nest may be in a hole in a tree, bank or building or may be an oval, pensile struc-

ture. The eggs are plain or spotted.

A number of starlings are kept as cage birds, notably the mynah or grackle (q.v.) of the Indian region that can learn to talk. The expeckers of Africa, genus Buphagus, that eat ticks off the skin of

hoofed animals are aberrant starlings (A L RD)

STARNBERG, a village and health resort of Germany, situed in upper Bavaria, on the Starnberger See, 16 m. S from Munich by rail Pop (1933) 4.879 The Starnberger See (or Wurnsee) is a fake 12 mi long, 3 mi wide and covering 23 go mi. Its greatest depth is about 400 ft. On the Rosennsel, an island in the lake, remains of lake dwellings were found

See Ulc, Der Wurmsel in Oberbayern (Leipzig, 1901)

STAR-NOSED MOLE (Condylura cristata), a North American species In habits it resembles the other moles, but is distinguished by the presence of a ring of tentacles, probably tactile, round the nostrils (See Insections)

STARODUB, a town of the Bryansk oblast, Russian S F S R, about 7; ml. SW of Bryansk. It is the terminus of a branch railway Fop 10,919 Russian princes contended with one another for it in the 11th and 12th centries. It was destroyed by the Mongois in the 15th entire, In the 15th and 16th centures the Russians and Luthunians struggled for it, it became a Polish stronghold in the 17th century, but was handed over to Russian in the 15th centure 
STARVATION is a state of extreme malnutrition caused by the long-continued deprivation of essential nutrients. It usually tresults from insufficient food intake, either because food is not available or because those person is unable to eat, due to illness or other factors Starvation may also result from disturbances in digestion, absorption or utilization of food. When the food intake in sufficient to supply the energy requirements of the body, the necessary energy must be supplied by a breakdown of the body tissues. The fat depots are first utilized, and when these are exhausted the tissue proteins are broken down. The severity of the starvation is related to the degree of the ensuing protent deficiency. Conversely, starvation is best combated by diets rich in proteins.

STAS, JEAN SERVAIS (1813—1807). Belgian chemist, was born at Lowau no Aug, at, 1813. He studied for a medical career and took his doctor's degree, but soon turned to chamsity, in 1835 the grand admission to, J. B. A. Duman's (n.P.) laboratory in Paris in order to continue a research on phloridsin which he had begun in an atte in his father's house, and he was associated with that chemist in several researches, including his redetermination of the atomic weight of carbon. In 1840 he left Paris on his appointment to the chair of chemistry at the £cole Royale Millitare in Brussels. There he remained for more than a quarter of a century, but he was then obliged to resign because of a malady which affected his speech. He was appointed to a post in connection with the mint, but gave it up in 1872 and spent the rest of his life in retirement in Brussels, where he died on Dec. 13, 1891. Star's lower than the start of the s

STASINUS, of Cyprus, according to some ancient authorities the author of the Cypris (in 11 books), one of the poems belonging to the spit of the measurement of the Hegestas of Salamine the company of the Hegestas of Salamine of the Cyprus of the Hegestas of Salamine events leading up to the Trojan war, such as the judgment of Paris and the rape of Helen. It is probable that the list of the Trojans and their allies (Islad, il, 316-876), which formed an appendix to the catalogue of the Greek shaps, is abridged from that in the Cyprus. Proclus in his Chrestomathia gave an outline of the poem (preserved in Pholius, cod, 240).

See D. B. Monro, appendix to his edition of Odyssey, xili-xxiv (1901); T. W. Allen, "The Epic Cycle," in Classical Quarterly (Jan. 1908, et seq.); and Homesur Posses.

STASSFURT, a town in the former Prussian province of Saxony, Ger., and after 1045 in Saxony-Anhalt, one of the chief seats of German salt producane, it is on the river Bode, 20 mi. S.W. of Magdeburg by rail to Ascheraleben. Pop. (1939) 15,783. The systematic exploitation of the salt beds to which the town owes its prosperity dates from 1856 only Beatles the rock sait, the saline deposits yield deliquescent salts and other saline products, which encouraged the foundation of numerous chemical factories. For about 50 years prior to World War I the bulk of the potasts used throughout the world originated in the Stassfurt mines The deposit underlies an area of about 100 sq mi Production continued to be heavy, although Germany's monopoly after 1918 was no longer complete.

STATE: see Sovereigniy

STATE, ACT OF, the plea of "act of state" in English law means primarily a defense raised by the crown on behalf of a servant of the crown, who is sued in the English courts for some wrongful act ratified by the crown In this sense the plea is not recognized by the English courts who, in rejecting it, have uniformly held that, as the king cannot do a wrong so also "it follows that the king cannot authorize a wrong" The only exception to this rule is in the case of a wrongful act done to an alien who, in such a case cannot sue (Buron v Denman [1848] 2 Ev. 167) if the act was done outside British territory and was ratified by the crown, but it has recently been held in Johnstone v Pedlar 90 LJP.C. 181 that if the act complained of was done to him in British territory he has the same right to sue as a British subject and the defense of "act of state" is, in that case, equally mapplicable But the term is also used in another and less questionable sense. It will be entertained by English courts where the acts in respect of which an action is brought are "transactions of independent states between each other," such as those arising out of the execution, or nonexecution, of a treaty, the succession of the crown to a foreign territory by cession or conquest, and the like For example, a concession granted by the chief of native territory is not enforceable whether by Petition of Right or otherwise in British courts by the grantees against the crown, on succeeding to the territory by annexation (Cook v Sprigg [1897] A C. 572) So too the contractual obligations incurred, whether toward a British subject or an alien, by a foreign state are not binding on the crown, after its conquest and annexation by the crown, unless the crown expressly elects to adopt them (West Rand Gold Mining Co. v. the King [1905] 74 LJK B. 753); for annexation is an "act of state" of an international character. In such cases the title of the subject has originated with a foreign government, not with the crown. If the contract or concession in question had originally been made by the crown itself, it would be another matter. Even in the case of a British protectorate the crown may plead "act of state" as a defense to claims in respect of expropriation of native territory because the crown in such a case is acting in territory which is not British (see the recent case of Sobhuza II, v. Miller [1926] A.C. 518). So too claims arising under a treaty are not enforceable against the crown unless and until the treaty, which is an international act, becomes part of English municipal law by being incorporated in a statute. The negotiation of the treaty is an "act of state" into which, and its meaning, the courts cannot enquire. In this sense the declaration of war and the making of peace by the sovereign is also an act of state As Lord Somer put it in Johnstone v Pedlar (Op. cit. at p. 704) "Municipal Courts do not take it upon themselves to review the dealings of State with State and Sovereign with Sovereign." On the other hand the mere fact that some act, wrongful per se in English law, was done in execution, or alleged execution, of a treaty made by the crown against the person or property of a British subject is a defense that would never be entertained by the courts in action against a servant of the crown, for, while a treaty cannot confer new rights, enforceable at law, upon a British subject, neither can it deprive him of any of his existing rights under English law. This was specifically laid down in Walker v. Baird [1892] A.C. 491 where in an action for trespass an officer of the crown put in the plea of "act of state" in that he was acting in the execution of a convention with the French government

ADTHORETES:—Sir W. Harrison Moore, Act of State in English Law; Bellot's edition of Pitt Cobbett's Cases and Opinions in International Law,

STATE, DEPARTMENT OF: SEE GOVERNMENT DE-

STATE GOVERNMENT (U.S.). At the close of the Revolutionary War in 1783 the 13 British colonies in America be-

once have begun to function in international relations on an equal legal basis with all other sovereign states But they had already created a confederation under a document known as the Articles of Confederation However, this document, and membership in the confederation, did not impair their status as free and independent sovereign states Each had joined voluntarily, and each one was free to withdraw Their sovereign powers as separate states were not affected

This confederation existed until the constitution of the United States was adopted by the 13 states in 1789 By that action they ceased to be free, independent, sovereign states. They were not free to withdraw from the newly created union, they had irrevocably surrendered certain very important powers to the new national government, and they had no status whatever as sovereign states in international relations. Some confusion grows out of the fact that they continued to be called states, for in the terminology of political science the very word state had generally been supposed to imply sovereignty and independence. Certainly by the close of the 19th century this was no longer true, if indeed it ever was, for states like France and Sweden are independent and sovereign while states in the American Union are not.

The constitution brought into being a federal system of government It created a national government usually called the federal government, and it also preserved the integrity of each of the states and their separate governments. An effort was made clearly to divide powers between the federal government and the states. The powers of the federal government are enumerated and delegated, se, the federal government can do only those things which the constitution says it can do. The powers of the states are inherent and residual, se, each of them can exercise within its borders all governmental powers which are not delegated to the federal government, or not specifically forbidden to the states, or reserved to the people. Thus it is impossible to enumerate the powers of the states One can enumerate the powers of the federal government and the things the states are forbidden to do. The states possess all remaining powers

It is to be observed that under this federal system the national government has no power to coerce states, to use force upon them, or to compel a state to do or not to do any particular thing. The national, or federal government has abundant power to compel people, as individuals, anywhere within its jurisdiction, to obey its laws, passed in accordance with the constitution That is all the power the federal government needs-power to enforce its laws upon people who try to resist, however numerous they may be, or in whatever state they dwell. Such power is wholly adequate; and the need for coercing a state cannot arise. If unhappily the people of a given state were to endeavour to resist the enforcement of a federal law, the federal government would proceed to enforce it upon those people, as people, and not upon the state as a state.

This fact is immensely important. It is perhaps the most significant feature of the United States federal system. It is in this way that the authors of the constitution sought to avoid war as between the United States, and one or more of the states composing the union. Armed force applied to a state is war. The federal government has no power to make war upon a state and does not need such power. This feature of the federal system is often misunderstood by people who advocate federalism on the international level and propose to give the international federal government power to police international society and compel states to obey. That is precisely what the authors of the US. constitution sought to avoid. They came close to performing a miracle in the realm of political science. Only once has the system failed to work and that was at the time of the Civil War.

The constitution guarantees the boundaries of each state and provides for the admission of new states to the union There were 48 in 1946. Whether or not the outlying dependencies can be admitted as states is a question which had not been settled. Each of the states has exactly the same power. Once admitted to the union the powers of a state are determined by the provisions of the constitution, and they apply to all in exactly the came 13 independent sovereign states. Presumably they could at same way. There is some confusion about this point because the legislatures of various states do not have the same powers, and governors of some states have much more power than governors of other states. These variations grow out of the fact that each state provides for its own agencies of government in its own constitution. The states as states have equal and identical powers

The federal government cannot deprive a state of powers reserved to it by the constitution. Thus it is improper to say that the federal government has power superior to that of the states. The federal government can do only what the constitution says it can do, but within these limits the federal law prevails, and provisions of state constitutions and state laws which interfere with the enforcement of federal laws are null and void. Beyond these limits the state prevails, and the federal government cannot intefere. This basic theory of the constitution is easily stated. The practical application of it has produced a multitude of harsplitting interpretations which would fill many volumes. Suffice it to say, the supreme court of the United States is the ultimate authority in the matter of determining the dividing line between state and federal power.

Each state may provide for its own government subject only to the few limitations in the federal constitution. Each state has a written constitution, in essential features similar to the federal constitution They all contain bills of rights limiting their own governments. They all provide for the tripartite division of powers into separate branches: legislative, executive and judicial. They all apply the doctrine of judicial review under which the courts interpret and apply the provisions of the state constitution They all provide for popularly elected governors. In every state except Nebraska there is a bicameral legislature-a senate and a so-called lower chamber, usually at least twice as large as the senate. Members of both houses are popularly elected from districts, in many states the counties. No state has provided for a cabinet truly comparable to the cabinet in the federal government, although some states have experimented with the idea. In a great majority of the states the high administrative officers, such as the secretary of state, treasurer, auditor, attorney general and secretary of agriculture, are elected and not subject to the administrative control of the governor.

It is not possible to go much further in describing state government in the United States without qualifying each statement with such words as "usually," "generally," "in most states," or "in a majority of cases" The reason is that although the institutions of state government are very similar, they do differ somewhat. To the casual observer and to the ordinary clitten who travels from one state to another the systems of government are so nearly alike that he is scarcely conscious of the fact that he has moved from one jurisdiction to another. He takes it for granted that the political and legal system which prevails in his own state also prevails in another; and m general he is right.

Thus each state has its own complete system of civil and criminal law. There are variations but they are not particularly significant to the ordinary citizen.

Each state has power to determine who may vote, subject only to the provisions of the federal constitution which say that the right to vote shall not be denied on account of race, colour or sex. The federal constitution does not guarantee the right to vote to anyone—to citizens over 21 years of age, to women, to soldiers or to Negroes. It does not forbid poll tax requirements or property qualifications. One gains a right to vote under state law, But the all-important fact is that the right of all citizens over 21 years of age to vote has been established in all states, with some qualifications is some states, usually involving term of residence and literacy.

The structure of courts is much the same in all the states, and however the closely the model of the federal judiciary. The most notable difference between the federal judiciary and that of the states is that in most of the latter the judges are elected instead of being appointed and hold office for fixed terms.

Administrative departments, offices and agencies to be found in all the states are quite similar but not identical either in organization or as respects relationship to each other and to the governor. A marked tendency in the 20th century has been to reduce greatly the number of independent administrative agencies, to merge them into large departments of administration and to stiengthen the power of the governor over them. Further generalization would serve little purpose. The facts with respect to each of the states can be found in their constitutions and laws and in the texthooks.

The same observations can be made with respect to the structures of local government and the public school systems. They are very similar but not identical.

Throughout the entire history of the United States there has been an apparent tendency for the national government to uncrease its powers and to extend its scope of operations, often, it is said, "at the expense of the states." From 1932 this tendency has been greatly accelerated and some observers have been prompted to predict the ultimate subordination, if not the virtual extinction of the states. Political theorists have often commented upon the instability of a federal system, saying that one of two things is likely to happen: either the national government will acquire such power as to lead to the extinction of the component units—the states; or, the states will be so jealous of their own powers as to lead to the paralysis of the national government and the ultimate collaises of the union

After a century and a half of experience there seems to be no remote possibility that either prediction will be fulfilled in the United States The powers of the national government have indeed been expanded This has come about largely because of the application of the idea of loose or broad construction to the grants of power to congress, chiefly the power to regulate commerce among the states, and the power to tax for the general welfare; while the states have been held in check by the strict application of that provision of the fourteenth amendment to the constitution which says, "No state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States, nor shall any state deprive any person of life, liberty or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws But on the other hand the powers of the states have expanded also and seem destined to continue to expand. The states have

also and seem destined to continue to expand. The states have vast power in the realm of civil and criminal law, domestic relations, property rights, taxation, the regulation of busness, agriculture, the professions and commerciar leationships. The states have almost unlimited power in such matters as public education, social betterment, public health and welfars, the building of highways and public works and the control of public withintees and intrastate commerce. Thus the opportunities for the expansion of the profession of the profession of the control of the looked by those who are more impressed by what seem to them to be the encroachments of the federal government upon the states. Many other countries, chiefly in the western hemisphere, have

Many other countries, chiefly in the western hemisphere, have established federal systems of government similar to that of the United States. Serious difficulties frequently have arisen, leading sometimes to a complete breakdown of the system Although many factors have contributed to these failures the wesk spot in the systems means to be the supreme court. It is that agency which passes finally upon questions involving the powers of the states and of the national government. If the court becomes corrupt or incompetent, or if the people are unwilling to accept its decisions, the entire system is in danger of collapse Both the national government and the states must rely on the court to protect them against encroachments.

STATEN BLAND, or the borough of Richmond, one of the

STATEN ISLAND, or the borough of Richmond, one of the five countes of New York city, is in New York harbour, south of Manhattan, between New Jersey and Brooklyn. Thangular in shape, the island is 13,9 mil. long, 7,3 mil. across at its widest part, has 35 mil. of water front and a land area of 57 sq.mil. The-population was 191.075 by the 1950 federal census and 174.441 in 1940. The larger communities are Port Richmond, West New Brighton, New Brighton, St. George, Temphinsville, Stauleton,

New Dorp, Great Kills and Tottenville,

The county seat, formerly at Richmondtown, was moved in 1920 to St. George, the northeastern tip of the island and central point of communication with the rest of the city Transportation to Manhattan is provided from St. George by municipal ferries and to Brooklyn by privately operated ferries

Three vehicular bridges connect Staten Island with the state of New Jersey the Outerbridge crossing, extending from Tottenville to Perth Amboy, N J.; Goethals bridge, from Holland Hook to Elizabeth, N J .; and the Bayonne bridge, from Port Richmond to Bayonne, N I.

Transportation facilities on Staten Island itself consist of surface electric trains, steam freight service and an extensive bus

The census of manufactures in 1947 listed 173 industries, the largest being shipbuilding, oil refining, metal working, smelting and refining, and the manufacturing of soap, dental supplies, fireworks, colours and dyes and building supplies The major shipyards are on the north shore; the east shore is the site of shipping terminals including the New York foreign trade zone no 1, or free port, a municipal area used for shipping, storing and packing commodities, now privately operated

About 70% of Staten Island's families own their homes. There are 627 mi. of streets, 126 churches, 83 private and public schools, 5 hospitals, 7 public libraries and 47 city parks and golf courses,

with a total area of 2.86r ac.

There are two liberal arts colleges, the largest being Wagner Memorial Lutheran college, a coeducational institution with a 53-ac campus on Grymes hill, and Notre Dame College of Staten Island, a four-year institution for women, also on Grymes hill Wagner houses the Edwin Markham Memorial library, left to the college in his will by the poet, who lived in Westerleigh, Staten Island, until his death in 1940.

Points of interest are the Barrett park zoo, the museum of the Staten Island Institute of Arts and Sciences, the Richmond Historical museum, U.S. marine hospital. Seaview hospital. Silver Lake park and reservoir, Sailors' Snug Harbor, U.S. coast guard base and lighthouse service and the US quarantine station.

Among the 45 historic houses standing is the Voorlezer's house (1696), Richmondtown, the earliest known elementary schoolhouse in the country. A plan was undertaken to restore that area to its original pre-Revolutionary War state and maintain it as a historic site.

History.-When discovered by Europeans, Staten Island was inhabited by a few Aquehonga Indians, a branch of the Raritans. The first land grant was made by the Dutch West India company

After several settlements by white men, unsuccessful because of Indian attacks, the first permanent settlement was established in

1661 at Oude Dorp (Old Town) at South beach.

The island was named "Staaten Eylandt" during the period of Dutch control, in honour of the states general, the governing body of the Netherlands. The name "Richmond" was derived from the town and dukedom of Richmond in Yorkshire, Eng.

In 1668, according to legend, in order to prove that Staten Island was part of New York rather than New Jersey, the duke of York commissioned Capt. Christopher Billopp to sail around the island in 24 hr. Billopp, according to the story, made the trip within the time limit and was rewarded for this and other services with a grant of 1,163 ac, at the southern end of the island, now Tottenville

In the Billopp, or "Conference," house in Tottenville on the southern shore of the island, Lord Howe on Sept. 11, 1776, met with Benjamin Franklin, John Adams and Edward Rutledge, three representatives of the Continental Congress, to discuss reconciliation with England. The house has been preserved as a historic landmark.

Staten Island did not become part of New York state by law until 1892. In 1896 it became one of New York city's five

STATE RIGHTS, a term used generally in political science to denote those governmental rights which belong to the individual states of a federal union, there being a certain sphere of authority in which these individual states may act without interference from the central government Thus, in the United States there were certain rights reserved to themselves by the states when forming the union under the constitution of 1787. These rights the central government is by fundamental law bound to respect, and they can be reduced only by amendment to the con-

For 1,000 years the various German states were so jealous of any curtailment of their individual rights as to prevent the formation of an efficient federal government

In federal unions, such as Mexico and Brazil, where a central authority existed first and created the states, the belief in state rights is much weaker than it is in unions composed of originally independent states

The rights of a state are said to be delegated when, as in Mexico, Biazil and Colombia, the constitution is created by a central national authority which also makes the states, state rights are residuary when independent states unite to delegate by a constitution certain powers to a central government, as in the case of the United States, Switzerland and, until 1905, Sweden-Norway History shows that states forming unions of the second class are certain in aftertime to deny or assert that the sovereignty of the state is one of the rights reserved, according as the state belongs to a stronger or weaker section or faction, state sovereignty being the defense of the weaker state or faction, and being denied by the stronger group of states which controls the government and which asserts that a new sovereign state was created by a union of the former independent ones. This dispute is usually ended by civil war and the destruction of state sovereignty.

The evolution of state rights as shown in the history of the United States is typical. Thirteen independent states formed a union in 1787 under a constitution reserving certain rights to the states The sphere of the state authority embraced most of the powers of government, except, for instance, those relating to foreign affairs, army and navy, interstate commerce, comage and the tariff; the powers of the central government were specified in the fundamental law. Most of the states claimed at one time or another that sovereignty was one of the reserved rights of the states and on this theory the southern states acted in the secession in 1861. The war that resulted destroyed all claims of state sov-

ereignty

The other rights of the states consisted of those not delegated to the central government or forbidden to the states by the constitution. In case of doubt the presumption was in favour of the state. Since the beginning, however, the central government has gained strength at the expense of the states, seldom by direct usurpation (except during the Civil War and Reconstruction. 1861-76), but indirectly through use and custom, as the country and people developed and new conditions of government arose The field of state rights has not increased, while centralization has slowly but surely taken place.

The central authority in the United States, formerly affecting the average citizen but little, now touches him in many of the activities of life and sometimes intrudes even into the domain of local self-government. The history of the decay of state rights makes it seem doubtful if the federal form of government is a permanent one, or 1s only a transient form between independent state governments or loose confederacies and a centralized national government.

STATE'S EVIDENCE, the term used in the United States for evidence given by an accomplice upon promise of pardon, STATES-GENERAL, the English translation of (1) the states-general of the Duich Netherlands. The name in both cases signifies the assembly of the estates of the realm, as distinct from provincial assemblies of states, it is thus the equivalent of the English parliament, of the Cottes in Spain, or the diet of the Holly Roman empire, which the states-general resembled in their original constitution

In France the states-general were first summoned in 1302 by Philip IV for the purpose of giving him moral support in his quarrel with Pope Boniface VIII They consisted of representatives of the three orders of clergy, nobles and commons (taers état, third estate), an arrangement which survived to the end, though their composition, as well as their effective powers varied greatly at different times. For various reasons (notably the disorganization occasioned by the Hundred Vears' War and the religious wars of the 16th century) they never secured the power over taxation and legislation early obtained by the English parliament, and after 1615 they were never summoned util 1789, when they transformed themselves into the National Constituent assembly This seasombly consisted of the representatives of the three orders sitting together, but the states-general had ceased to east (see Fankor Hustory).

In the Netherlands the convocation of the states-general, consisting of delegates from the provancial extates, dates from about the middle of the 1sth century, under the rule stee dates of Burgundy. The name was transferred, after the extension of the northern Netherlands from the Spanish dominions, to the representatives elected by the seven sovereisp provincial extrate for the general government of the United Provinces. The states-general, in which the voting was by provupors (each province having one vote) was established from 1593 at The Hague. The states-general came to an end after the revolution in 1795, with the convocation of the National assembly (March 1, 1796), but modern Holland continues to use their name for its national legislature, which consists of the first chamber and the second chamber. (See HOLLAND, HARDY)

STATES OF THE CHURCH or PAPAL STATES, that portion of central Italy which, previous to the unification of the kingdom, was under the direct government of the see of Rome. Area in 1859 was 16,000 8 sq mi; pop. in 1853, 3,124,758.

With the exception of Benevento, surrounded by the Neapolitan province of Principato Ulteriore, and the small State of Pontecorvo, enclosed within the Terra di Lavoro, the States of the Church formed a compact territory, bounded on the N.W. by the Lombardo-Venetian kingdom, N.E. by the Adriatic, S.E by the kingdom of Naples, S.W. by the Mediterranean, and W by the grand-duchy of Tuscany and the duchy of Modena. On the Adriatic the coast extended 140 mi, from the mouth of the Tronto (Truentus) to the southern mouth of the Po, and on the Tyrrhenian Sea 130 mi from 41° 20' to 42° 22' N latitude The former papal territories are now comprised within the Italian provinces of Bologna, Ferrara, Forli, Ravenna, Pesaro and Urbino, Ancona, Macerata, Ascoli-Piceno, Perugia, Rome and Benevento. For the origin of the territorial jurisdiction of the pope see PAPACY With the moral and ecclesiastical decay of the papacy in the 9th and 10th centuries much of its territorial authority slipped from its grasp; and by the middle of the 11th century its rule was not recognized beyond Rome and the immediate vicinity. By the Treaty of Sutri (Feb. 1111) Paschal II was compelled by Emperor Henry V to surrender all the possessions and royalties of the church; but this treaty was soon repudiated, and by the will of Matilda, Countess of Tuscany, the papal see was enabled to lay claim to new territories of great value. By the capitulation of Neuss (1201) Emperor Otto IV recognized the papal authority over the whole tract from Radicofani in Tuscany to the pass of Ceperano on the Neapolitan frontier-the exarchate of Ravenna, the Pentapolis, the March of Ancona, the bishopric of Spoleto, Matilda's personal estates, and the countship of Brittenoro; but much of the territory described remained for centuries an object of ambition only by the popes. The actual annexation of Ravenna, Ancona, Bologna, Ferrara, etc., dates from the 16th century.

ground-swell of the French Revolution, but they reappeared in 1844. In 1849, they received a constitution of the kingdom of Italy in 1860 they were reduced to the Comraca of Rome, the legation of Velletin, and the three delegations of Viterbo, Cività Vecchia and Frosinone, in 1870 they disappeared from the political map of Europe From that time, the popes retired within the Vitican as self-constituted prisoners. This stitution was changed by the Latenan tresty between the Holy See and the kingdom of Italy (signed Feb 11, 1939), which recognized Pope Pins XI as sovereign of a clearly defined territory, entitled "Original Control of the Vatican". Therein the Holy See has full and care control of the Vatican".

STATE SUCCESSION. The extent to which a succession

State is bound by the obligations of its predecessor constitutes one

of the most difficult problems in international law. The clearest statement is probably that contained in the report of the Transvaal Concessions Commission, see Parl Pap South Africa, 1901 [Cd 623]. The principles which the commissioners regarded as applicable to the determination of questions relating to various concessions granted by the Transvaal Government in view of the conquest and annexation of the Transvaal by Great Britain are as follows :- (1) "It is clear that a State which has annexed another State is not legally bound by any contract made by a State which has ceased to exist, and that no court of law has jurisdiction to enforce such contracts if the annexing State refuses to recognize them, see Cook v. Sprigg (1899) A C. 572 But the modern usage of nations has tended in the direction of the acknowledgment of such contracts After annexation, it has been said the people change their allegiance, but their relations to each other and their rights of property remain undisturbed, U.S. v. Pencheman, 7 Pet. 51, and property includes rights which lie in contract, Soulard v U S, 4 Pet 54" Concessions of a mixed public and private character probably continue to exist after annexation until abrogated by the succession State There would not appear to be any distinction between cession and annexation. Private rights should be respected, but this is based rather on ethics than law (2) "Though we doubt whether the duties of an annexing

State towards those claiming under concessions or contracts . . . have been defined with such precision in authoritative statement or acted upon with such uniformity in civilized practice, we are convinced that the best modern opinion favours the view that as a general rule the obligations of the annexed State towards private persons should be respected. Manifestly the general rule must be subject to qualification, as that an insolvent State could not by aggression which practically left to a solvent no other course than to annex it, convert its worthless into valuable obligations; again an annexing State would be justified in refusing to recognize obligations incurred by the annexed State for the immediate purposes of the war against itself, and that probably no State would acknowledge private rights the existence of which caused or contributed to cause the war which resulted in annexation." (3) The principle to be adopted was that proclaimed by the Prussians upon the annexation of Hanover "we will protect every one in the possession and enjoyment of his duly acquired rights." (4) "The acceptance of this principle clearly renders it necessary that the annexing Government should in each case examine whether the rights which it is asked to recognize have, in fact, been duly acquired. (5) Thus a concession may properly be cancelled when "(a) the grant of the concession was not within the legal powers of the late Government, or (b) was in breach of a treaty with the annexing State, or (c) when the person seeking to maintain the concession acquired it unlawfully or by fraud, or (d) has failed to fulfil its essential conditions without lawful excuse," (6) A concession may be cancelled when its maintenance would be injurious to the public interest.

to the public interest.

STATESVILLE, a city of North Carolina, U.S.A., county

much of the territory described remained for centuries an object STATESVILLE, a city of North Carolina, U.S.A., county of ambition only by the popes. The actual annexation of Ravers, east of Ireedell county; 130 ml. W. of Raleigh, on federal high-na, Ancona, Bologan, Ferrara, etc., dates from the 16th century, ways 21, 64 and 70; served by the Southern rallway. The popular of the Church were submerged for a time by the lation was 16,765 in 1950; 11,440 in 1940 by federal census,

The city is in the upper Piedmont section of the State, at an inglitude of 960 feet Statesville was laid out in 1790 as the capital of Ireeld county organized 1783, hear old Ft. Dobes, which was twice defended against the Indians by Damel Boone, which was twice defended against the Indians by Damel Boone, the most famous of American backwoodsmen During the Cvil War Govennor Zebulon Vance took refuge in Statesville when Sherman entered Raleigh (April 13, 1865).

STATIC, a term in radio denoting conduction or charging current in an antenna (q v) resulting from physical contact between the antenna and charged bodies or masses of gas In America this term is synonymous with atmospherics

STATICS, the branch of mechanics which discusses the conditions of rest or equilibrium of forces (from Gr. root στα, stand) (see Mechanics)

STATIONARY MACHINERY: see Processing Ma-

STATIONARY MACHINERY: See PROCESSING MA-

STATIONERY. The word now covers all writing materials and implements, together with the numerous appliances of the desk and of mercantile and commercual offices. The principal articles and operations of the stationery trade are dealt with under such headings as BOOKENDRING; OPPICE APPLIANCES; INK, LITTROGRAPHY, PREFE PER and PENOT.

LITHOGRAPHY; PAPER, PEN and PENCIL.
STATIONS OF THE CROSS, a series of 14 pictures or images representing the closing scenes in the Passion of Christ, viz., (1) the condemnation by Pılate, (2) the reception of the cross, (3) Christ's first fall, (4) the meeting with His mother, (5) Simon of Cyrene carrying the cross, (6) Veronica wiping the face of Jesus, (7) the second fall, (8) the exhortation to the women of Jerusalem, (9) the third fall, (10) the stripping of the clothes, (11) the crucifixion, (12) the death, (13) the descent from the cross, (14) the burial. Sometimes a 15th-the finding of the cross by Helena-is added; on the other hand in the diocese of Vienna, the stations were at the end of the 18th century reduced to eleven The representations are usually ranged round the church; sometimes they are found in the open air, especially on the ascent to some elevated church or shrine. The normal form of the devotion, which began among the Franciscans, is to visit the stations of the cross wherever represented, and exercise a devout meditation on passing from station to station

See article "Stations of the Cross" in the Catholic Encyclopaedia

STATISTICS. The name statistics was first applied to collections of data relating to matters important to the State, such as the numbers of the population, the yield of taxation, the value of trade carried on within the territory of the State or between that territory and other parts of the world, the mortality from particular diseases and from all causes together, etc., and to the study and interpretation of such data. The data were not at first numerical and later not exclusively numerical, but the precision and convenience of data expressed in numbers, as compared with other forms of statement, have led to the more general cultivation of arithmetical data and to the common use of the term "statistics" as if it related exclusively to data expressed in numerical form. At the same time, the numerical data to which the name "statistics" is generally applied are not limited to such as have some connection with the organization or administration of the State, the methods appropriate to the study of statistics being, broadly speaking, the same whether the data under consideration relate to human communities or are concerned with any other branch of knowledge or investigation

Statistical Tables.—The simplest way of arranging numerical records is to set them out in tabular form. We may, for example, ascertain the amount of sugar consumed in a given country in each year of a given period. A table may be drawn up in which each line contains the figures for the year the date of which is shown at the beginning of the line If each line relates to the year next following that dealt with in the preceding line, the sequence of figures of consumption will enable us to determine whether, and at what rate, the yearly consumption of sugar increased in successive intervals of years. The increase of population from year to year observed in most countries is an obvious influence tending to increased use of any popular article of consumption, and it will be advantageous to add, to the figures show

ing the total consumption of sugar in the country, another series of figures showing the number of persons luving in that country in each of the years covered by the table. To the columns containing (1) the dates of the years to which the information relates, and (2) the total amounts of sugar consumed in the respective years, there will thus be added (3) a column showing the numbers of persons concerned in the consumption of these quantities of sugar. The significance of this last column in relation to the preceding may be made clearer by the addition of a fourth column (4) deduced from the two preceding by dividing the quantity of sugar shown in any line of the table by the number of the population shown in the same line, thus obtaining the average amount of sugar consumed per head of the specified population. The form of the table is sufficiently indicated by means of the lines relating to the United Kingdom in ten years, 1903 and 1913, given below:

Consumption of Sugar in the United Kingdom											
(1) Year	(2) Total con- sumption thou- sand cwt.	(3) Population thousands	(4) Consumption per head, lb								
1903 .	28 847	42 247	76 5								

If to this table further columns are added or a new table is drawn up, in which data relating to the consumption of tea in the same country and in the same years is set out, we obtain two sets of facts the comparison of which may prove of intest and importance. We can ascertam whether the variations in the consumption of sugar and of tea were related.

Graphs.—It is frequently of advantage to set out in diagrammatic form such tabulated results as those referred to, as at least the broader features of the comparison of two or more series of

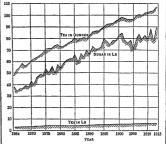

FIG 1—GRAPH SHOWING CONSUMPTION PER HEAD OF TEA AND SUGAR IN THE UNITED KINGDOM IN EACH YEAR, 1864—1913 Quantities in stock at the end of each year are not taken into account

figures can often be seen more clearly in this form. Such simple graphical comparisons are familiar through their use in meteorological reports where readings are shown by the upward and downward movements of a line crossing from left to right a series of vertical lines marking the house of the day or the days of the week. The particulars of the consumption, per head of the population of the United Kingdom, of sugar and of tea in each of the years from 1864 to 1913, are thus shown in Fig. (1). A necessary precaution in planning such graphical comparisons is also ullustrated in the same diagram. The figures which are plotted relating to sugar show the average consumption year by year in lb. per head. The consumption of tea in lb. per head yields the

line at the foot of the diagram, the variations of which are so manner in which the individual observations are distributed is in slight as to suggest no similarity with those of the line showing sugar consumed If, however, the consumption of tea per head is expressed in ounces, it becomes clear that, though in individual vears the variations shown are by no means similar for sugar and for tea, over the whole period the increase was in approximately the same proportion for these two commodities1. The fluctuations were more considerable in the case of sugar, and the diagram suggests that, up to 1901, the quantities of sugar increased somewhat more rapidly than, and thereafter failed to maintain as great an increase as, those of tea

Even though graphs fall short, in the matter of precision of statement, of the numerical tables, they have the great advantage of enabling a large mass of figures to be grasped as a whole much more readily than is possible when those figures are presented in one or more tables

Averages and Dispersion.—A second illustration of statistical series is seen in the following summary of the heights of a number of men .-

Height in inches Number recorded	61 2	62	63	64	65	66	67
Height in inches Number recorded	68 126	69	70 87	71 75	72 23	73	74

The table may be interpreted as meaning that 126 were found between 5 ft. 72 in and 5 ft 82 in and similarly for other heights In tables such as this some method of dealing with cases falling exactly on the dividing line between two adjacent groups must be laid down, and a common method is to assign half the number found on the dividing line to each of the classes of which it forms the limit. This procedure may, of course, result in numbers in some of the groups which are not integers. The true average height of the 730 men covered by the table can be ascertained only by reference to a more detailed statement showing the height of each man exactly, instead of in a number of groups. It will be observed that 297 were not taller than 5 ft. 74 in., while 307 were 5 ft. 81 in. or more, the distribution being not quite symmetrical on both sides of the numerically largest group. The approximate average height was about  $\frac{1}{20}$ in less than 5 ft 8 in.

A table of this kind tells us, however, something more than the average height of the individuals represented. We note that 191 were not more than 5 ft. 61 in. in height and 198 were not less than 5 ft 94 in. in height. By calculation from the figures shown, assuming that the individual heights were distributed with approximate regularity along the intervals from inch to inch, the points representing 5 ft 6.3 in, and 5 ft, 9.7 in, would divide the series of heights so that one-quarter of the whole number fell below the former, and one-quarter of the whole number above the latter A similar calculation gives, as the point dividing the series into two equally numerous groups, 5 ft. 8-04 in. This last point is called the median of the series, and the two others are the lower and upper quartiles, the three points serving to divide the whole number examined into four groups of equal numbers of cases The distance between the upper and lower quartiles, in the case in question 3.4 in., gives the range within which the middle half of the instances recorded lay. This distance expresses much more definitely the degree of concentration of the individuals in the neighbourhood of the median height than, for example, the whole range (14 in.) within which all the measurements lie If a more exact description of the nature of the distribution than is afforded by the specification of the median and quartiles, but of the same general character, is desired, the group may be divided into a number of parts, e.g., into ten equally numerous

parts, the points of division being then known as deciles.

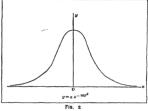

In many varieties of statistical problems it is found that the observations are distributed in a manner similar to that shown in the above illustration, and the question arises whether the form of the distribution is of a recognizably definite character, the determination of which can be of use in the interpretation of the results obtained. It is found that, in numerous cases, the

<sup>1</sup>Ci. Jubilee Vol. of the Royal Statistical Society, p. 257, where the late Professor Marshall used this illustration. The figures are based on imports less exports of sugar, excluding sugared goods.

close accordance with that of events dependent on pure chance. Such a case is presented by the following A number of balls, indistinguishable in size, weight or form, are placed in a bag, half of the balls being white and half black. If one ball be drawn from the bag, its colour, whether white or black, may be noted. The ball being replaced and the bag shaken, another drawing will give a result wholly independent of the first. The repetition of such drawings will furnish a record of runs of white and of black balls, some short, some long. The numbers of cases (a) of a change of colour in consecutive drawings (b) of sequences of the same colour of two, three, four, etc , in number, being noted, the material for a table is furnished, and this table would have a general similarity with that of the men's heights used above for illustration. It is possible to determine theoretically the relative frequency with which the various sequences would recur in a series of trials indefinitely extended

If, in a large number of drawings, sequences of  $x_r$  white (or of  $x_r$  black) balls are recorded on  $Y_r$  occasions, the total number n of drawings will be expressed by  $n=x_1Y_1+x_2Y_2+x_3Y_4+...$ +xrVr+... The relative frequencies of the different series are  $y_1$ ,  $y_2$ , etc., where  $ny_1 = Y_1$ ,  $ny_2 = Y_2$ , etc., and, when n is indefinitely increased, the relation between the x's and the v's is expressed by the formula  $y = a e^{-m\pi^2}$ , which represents a curve of the shape shown below in fig (2), known as the probability curve.

It is not proposed to enter into discussion of the character of the probability curve, or the interpretation of the variations. It will be sufficient here to point out that the equation given relates to a curve symmetrical in form to right and left of the position represented by x=0 The part to the right may be supposed to show the record of white sequences, and that to the left the

exactly similar record of black sequences, ie, of sequences in which white balls failed to appear

In any actual series of observations (e.g., of the colours of

balls drawn from, and returned to, a bag) the observed numbers expressing the frequency of different events will be found to differ more or less from those expressed by the curve, of the form given by the above equation, which is appropriate to the circumstances of the experiment. Prolonged trials would give results approximating to those derived from theoretical calculations and expressed in the shape of the probability curve. Thus, in the case of the heights of 730 men, it is probable that records covering larger numbers of men, of the same race and social condition and within the same limits of age as those from which the 730 were selected, would give a distribution of heights more closely corresponding to that shown by a typical probability curve than the numbers cited. If, for example, for every one actually covered by our table, 10 or 20 or 50 or 100 had been measured, closer correspondence with a suitably selected theoretical series would have been probable.

In considering the meaning of changes in the observed frequency of events, it is generally of considerable importance to ascertain what is the extent of variation that is as likely to happen as not, since the significance of actual variations can only be judged in relation to those which may have no significance at all in reference to the problem under consideration

Skew Distributions .- The normal probability curve, referred to above, is not the only form resulting from the theoretic consideration of chance events, and presenting close correspondence with statistical records of various kinds. The study of these forms, and of their theoretical bases, has been particularly active since the last decade of the 19th century. It will suffice here to mention that particular statistical problems are found to yield distributions of observations, not only symmetrical on either side of their mean, as with the normal probability curve, but also grouped more closely on one side of the mean than on the other The illustration from men's heights showed some small tendency to a skew shape, though it appears possible that the apparent deformation would, on extending the field of observation, be found to disappear and be shown to result from the fact that, in so small a number of cases as 730, the even representation of men of all heights in the population from which these cases were drawn had not been exactly secured. The following records of weights of men of 25 and less than 30 years of age and within half an inch of 5 ft. 6 m in height, shows a more marked skewness

i	Weight in lb. Number of cases	105	120	135	150	165	180	195 33	210
ı	Number of cases	17	722	2,175	1,346	485	155	33	3

In this case the average (or arithmetic mean) of the weights of the 4,956 mn is, on the assumption of continuous distribution, approximately 14,15 lb The median is at about 1 lb less, viz., 14c jb ln In the previous illustration of heights, the median was greater than the mean, so that the skewness shown is of opposite direction in the two cases.

This illustration serves also to show a third characteristic of statistical distributions of this kind Nearly four of every nine cases are included in that one of the eight groups of which 135 lb is the central point, this group being notably more numerous than any other. The weight 135 lb may be called, so far as the figures furnish a ready indication, the most generally occurring weight or the "modal" weight. The point in the distribution thus determined is called the "mode." A table like the above does not, however, give a very close measure of the central point of the group (covering a range of 15 lb) which would prove largest if we compared various groups such as 1271 to 1421 lb (the group shown) 127 to 142 lb, 128 to 143 lb., and so on. If the curve be found which represents the distribution in question, its highest point is the point the weight corresponding to which is the "mode" of the distribution, the most prevalent weight in the distribution under examination. Various problems in probability lead to curves of the distribution of chances which show the skewness that marks groups of statistical observations

Groups That Are Not Homogeneous.—A case that may, however, be mentioned is that in which the measurements obtained relate, not to a homogeneous group, but to a mixture of two or more groups. The manuer in which such a mixture might affect the characteristics of a distribution may be illustrated from the figures given below for the heights of a particular group of men. Suppose two such groups were found differing in the heights of multiple and the property of 
the individuals of which were half an inch taller than those of the original group If the distribution of the original group were such as could be precisely represented by an appropriate theoretical formula, the compound group would not be, in general, represented by the same formula. In some instances, it has been found possible to show that an observed group was so distributed as to be consistent with the assumption that it was made up of two groups of different characteristics, the members of which were mediaded within one and the same series of observations Such an analysis can clearly be of considerable importance with reference to the deductions to be drawn from the examination of the observed data.

Three Variable Elements .-- In what precedes, the statistical material considered has consisted of series of pairs of quantities, the values of the two quantities in each pair being related; for example, where one of the quantities is the height of a man, the other the relative frequency with which men of that height were observed We pass now to the consideration of series of three quantities, for example, where two of the quantities express the measures of different phenomena (which may be connected in some way, or may be independent) and the third expresses the relative frequency with which any combination of the other two occurs Such a series is represented in the table given below, which shows the proportions in which, over a period of years, in a particular country, marriages in which both bride and bridegroom had been married previously were distributed according to the ages of the brides and of the bridegrooms. The particulars might advantageously be set out in fuller detail, but the condensed table will serve quite well to illustrate the nature of the problems connected with the analysis of data of this kind

Ages of wives	Age	Ages of husbands at date of marriage									
at date of marriage	Under 25	25-34	35-44	45-54	55-64	65 and over	Total wives				
Under 25 25-34 35-44 45-54 55-64 65 and over	10 20 5	75 175 54 5	46 167 104 18 1	13 65 79 36 5	3 17 29 33 13	3 7 9 5	147 447 278 101 24 3				
Total husbands	35	300	336	198	96	26	1,000				

The table is to be read as follows: Of each thousand women married for the second (or later) time to men who had been married before, 447 were between 25 and 35 years old, and of these so married men under 25 years of age, 175 married men between 25 and 35, 169 married men between 35 and 45 and 17 men between 45 and 55. The other rows of figures will be read similarly, and the columns are to be read in corresponding manner, with the words "Subsand" and "wife" interchanced.

The columns, and also the rows, representing the age distributions of particular sections of the wives and of the husbands, are examples of skew distribution of numbers. It is clear, from the clustering of numbers in the neighbourhood of a band crossing the table from its upper left side towards its lower right side, that there is some association between the ages of the wives and the husbands, which are more often relatively inght logether, or relatively low together, than in other relations. The average age of the husbands is near 4x years and that of the wives somewhat

						-											
	Height in inches. Numbers in	60-61	6x-62	62-63	6364	64-65	65-66	66-67	67-68	68-69	69-70	70-71	71-72	72-73	73-74	74-75

The numbers in the last row represent a compound of two groups as numerous as the original group, the individuals of each of which were half an inch shorter than those of the original group, and another group, equal in number to the original group,

in excess of 34 years

Correlation.—If the average ages of the husbands shown in each row of the table be computed, and also those of the wives shown in each column, the two series of figures thus obtained show

hands and wives They furnish the measures of what are known as the regression of the ages of husbands on those of wives. and the regression of the ages of wives on those of husbands The two regressions would be complementary if the distribution represented complete linear correlation of husbands' ages and wives' ages When this complete correlation is not shown, a measure of the degree in which the distribution diverges from that corresponding to complete correlation is afforded by the socalled coefficient of correlation Between two series of quantities

$$x_1, x_2, x_3$$
 and  $y_1, y_2, y_3$ 

if the sums of the squares of each series,  $S(x^2)$  and  $S(y^2)$  be calculated, and the sum of the pairs of products x1y1, x2y2, x3y3 ie. S(xy) be also calculated, the fraction S(xy)/ $\sqrt{[S(x^2) S(y^2)]}$  gives the coefficient of correlation.

In the case represented by the final row and the final column of the last table, the calculation gives a fraction exceeding o The highest possible value for the coefficient is I The coefficient is a measure of the divergence between the two lines of regression in cases like that illustrated, those two lines coalescing when the correlation is complete. If the series compared are such that decreases in the one correspond to increases in the other, the calculated coefficient is negative. The range of values for the coefficient lies between o and 1 for positive correlations and between o and -1 for negative correlations Small values of the coefficient mean that the connection between the series is slight, and, in view of the extent to which, in actual observations, the records obtained are affected by disturbances having no relation to the matter under examination, no great significance can generally be attached to the occurrence of correlation coefficients of small magnitude

The class of problem of which the figures given in the last table furnish an illustration is one of great importance in statistical work. Thus the variation of the height and weight of men with their age, the questions relating to the transmission of characteristics from parents to children, the association of different diseases or defects and the results of combinations of treatment of diseases or defects, the interpretation of the results of variation in different features of the weather, for example rainfall and temperature, on crop yields and many other problems give rise to such dis-tributions, while the limitation of the illustration to the case of three kinds of variation should not be taken to imply that larger numbers of elements may not be considered

The practical application of the procedure of calculating coefficients of correlation is not confined to cases such as that in connection with which the nature of correlation was illustrated It may also be applied to determine, in cases such as that of the consumption of sugar and of tea, illustrated earlier, the closeness with which the variations in the two series of figures coincide In some cases it is of importance to compare, not two series the trends of which are, on the whole, similar, but two series of which the trends are different, though the variations from the general trend may prove to be similar in the two cases. Whether for diagrammatic representation, or for preliminary arrangement of material for testing by the calculation of coefficients of correlation, it is desirable to isolate the important features as far as possible. The relation between economic prosperity and the marriage rate is a problem that has attracted much attention, and in using as a measure of economic prosperity the value of the exports year by year, or of imports and exports together, the connection which appears in some periods may be obscured in later periods by other conditions which cause one or other, or both, of the curves compared to diverge from the trend previously shown. To a considerable extent the effect of these disturbing elements in obscuring the significant relation may be evaded by using for comparison, not the absolute measures, e.g., of the value of trade and of the marriage rate, but the proportion in which the figures for a given year are in excess or defect in comparison with those of the average of a series of several years of which the year under consideration is the middle year, or the final year.

the variation of the average ages of corresponding groups of hus- variations in time of phenomena under examination, are tested for closeness of fit by the calculation of correlation coefficients, it is possible to test whether one of the two series differs from the other mainly in respect of the time at which variations are greatest or smallest. In comparing two series such as

the sum of products used in calculating the correlation coefficient was conceived of as

$$x_1 y_1 + x_2 y_2 + x_3 y_3 +$$

It may be found that such product-sums as  $x_1 y_2 + x_2 y_3 + x_3 y_4 +$ 

$$x_2y_1 + x_3y_2 + x_4y_3 +$$

show significantly larger resulting coefficients than the productsum first named. If so, it may be taken as meaning that of the two phenomena the variations of which are compared, those variations are not contemporaneous, but the members of one series follow, or precede, those of the other by a roughly constant in-terval. The repetition of the calculations for several different intervals may furnish a measure of the lag of one of the two phenomena on the other

It has been stated that the lowest value of the correlation coefficient is zero. It may be added that when, in practice, a calculation of such a coefficient gives a result practically equal to zero, it is not to be concluded that there is no correlation between the quantities. The form given for the correlation coefficient was based on the assumption that the lines of regression were sufficiently nearly straight lines to render it unnecessary to call attention to their divergence from that form. In some cases in which a high correlation with non-linear regression exists, the coefficient calculated by the formula given will be small On the other hand, there are cases in which large correlation coefficients result from the formula of calculation, though the phenomena compared are, in fact, not related to each other. The principal cause of such apparently strange results is found in the fact that actual series of observations may be but small samples of the universe of phenomena of which they are taken as representative, and in small samples the securing of really representative results is not easily achieved We turn, therefore, to the consideration of some questions relative to sampling.

Sampling.-Two principal reasons lead to the use of statistics of samples in place of complete statistics of an exhaustive character covering the whole of the so-called universe of instances. One is that only portions of that universe may be accessible as sources of data, the other that the labour and expense involved in handling very large masses of statistics render it expedient to seek representative selections of moderate extent as the basis of the data to be submitted to detailed examination. In the latter case, it is to be supposed that the selection of instances is at the discretion of the investigator, and the practical question involved is the devising of a means that will ensure that the instances selected should give, as far as is possible, a picture in petto of the whole field of enquiry.

The most common method is to choose the instances in a manner that shall ensure that there is no concentration on those possessing any particular characteristic in preference to those lacking that characteristic. All cases are to be given an equal chance of selection; the sample is to be a random selection. It is only necessary to illustrate the kind of procedure that will secure that result. Suppose we have to select 200 cases from a total of (say) 20,000. We may, if the 20,000 are arranged in any kind of sequence, take the first, pass over 99 and take the case then next following, again pass over 99 and take the case then next following, and so on. Another method would be to place in a bag cards bearing the series of numbers from 1 to 20,000 and to draw from the bag 200 cards in succession, shaking the bag between each pair of drawings The numbers of the cards drawn would show what choice of cases from the complete series should be made, and any effect produced by the arrangement of the cases in a particular order, which might influence the result of the method of selection first named, would It may be noted that when two series of quantities, showing the tend to be avoided by the second procedure.

Random sampling has, as its object, as already stated, the securing of a comparatively small group possessing the same general characteristics 10, showing the same proportions in which each special feature is present or absent, as the complete series of cases. This may, in some conditions, be secured more effectively by deliberate selection of instances in which a number of characteristics are distributed in a manner similar to that in which the same characteristics are distributed in the mass from which the sample is taken This involves, of course, that, in respect of the characteristics used as guides, available records exist covering the mass.

Another mode of testing a sample in respect of its representative character is to divide it into two or more parts at random, and compare the characteristics of the separate parts Agreement between the parts is commonly taken as an indication that the sample is representative in character, though such agreement, or its absence, is not a final test. To illustrate, suppose the special case of random samples of men of specified age from a defined race and locality. Suppose a sample of 1,000 such men taken, and their characteristics examined for example, their average height, median height, the dispersion of these heights and other features of the distribution of heights may be determined. The process may be repeated for a second, third, etc., sample of 1,000 until we have (say) 1,000 sets of results derived from 1,000 samples each consisting of 1,000 units Taking one of the characteristics, say the average height, we may examine 1,000 results from the separate samples. It will almost certainly happen that these differ from one another but slightly as compared with the differences between the heights of the individuals in any one sample. But these averages would themselves generally possess a degree of variation, and their grouping according to their order of magnitude would furnish a frequency distribution having its own mean, median, dispersion, etc. This latter distribution would, in fact, indicate the degree of variability of the results obtained by sampling,

The study of the mathematical theory relating to the problems thus illustrated furnishes estimates of the answers to such questions as: what is the probability that the divergence of the mean value of a specified feature of the sample from the (unknown) mean value of the same feature of the universe from which the sample is drawn shall not be greater than a specified amount? The answers may be a guide to a decision on the questions of whether procedure by sample 1s satisfactory, and what size of sample may

be desirable to justify the use of the sampling method.

When procedure by sample is adopted because only data derived from samples are procurable, the investigation of the entire mass of cases being excluded, the use of methods aimed at securing that the samples are random or are representative is, generally if not universally, not a matter for consideration. It is, therefore, of the greatest importance to examine the conditions affecting the selection of the sample. It may be found that some bias in the selection is unavoidable, while the extent to which that bias affects the results may not be capable of estimation. To apply to the results of biassed sampling the tests and limitations determinable by theory for the case of random sampling may lead to error.

The relative stability of the relations between different groups of statistics relating to human communities and their organization was a feature that attracted attention at a very early stage of statistical enquiry. Changes in habits of masses of men are generally of slow development. The consequence is that any well ascertained sequence of phenomena in economics may be expected to be repeated, that is, the repetition of certain conditions may be expected to be followed by consequences of a definite character. The underlying assumption is the permanence of the essential determining features of the organism with whose manifestations we are concerned. The introduction of new conditions, not all of which may be obvious or ascertainable, may destroy that stability of relations on the faith of which future changes might be expected when observed conditions show particular mutual relations Not only new conditions, but also the deviations from uniformity recognizable in the comparison of different samples of one and the same universe of phenomena, must be kept in mind in forming any judgment of the probable future based on observations of the course of events in the recent past.

Sources of Statistical Data .- In the work of administration. the governments of most civilized countries are able to make exhaustive enumerations of various classes of events occurring within their territory A few examples are -the number of buths in successive weeks, months of years, the deaths in the same periods, the causes of deaths and the sexes and ages of the persons dving the amount of property or income serving as the basis of assessment to taxation of individual citizens, the value and quantity of each of various kinds of merchandise imported from or exported to other countries during any determined interval of time, the numbers of various kinds of animals existing in the country at selected dates, the length of the roads maintained at the public expense and of the railway tracks existing from time to time, the numbers of various kinds of vehicles for the use of which licences are required, the quantities of certain dutiable articles of food and drink on which duties are paid in successive months or years.

From time to time, generally at intervals of ten years, the total number of persons of each sex, the age of each being also recorded. is ascertained for each administrative subdivision of the country. and either simultaneously or on other, and possibly less frequent. occasions the number of persons engaged in each principal class of

occupation is also generally ascertained

Organizations of a private character, including corporate bodies, obtain, like the public administrative bodies, much information for their own guidance, some of which is made public. In some cases there results an exhaustive enumeration of events of certain kinds occurring within the country, in other cases a series of more or less representative illustrations of what has happened is furnished Thus the total weight of goods carried by railway may be available, while the quantities of gas, water or electricity supplied may only be made public by some of the undertakings supplying them. and the extent to which the ascertained aggregates fall short of the actual aggregates supplied may be variable in a degree that cannot be determined and may be of importance.

In addition to the data arising out of the general administration of a country, and those published by business organizations. statistical data may be obtained as the outcome of special enquiries by either of these classes of bodies or by private bodies or persons The latter class of data generally presents the characteristic just referred to as affecting some of the data obtained by business organizations, namely, that an exhaustive enumeration covering the whole country is not secured What is obtained is a record relating to a part, more or less typical of the whole so far as the matter under examination is concerned The principles to which attention was directed in the paragraphs relating to sampling apply to the statistics thus secured. (A. W F.)

apply to the statistics thus secured.

STATIUS. PUBLIUS PAPINIUS (c. A.D. 45-96), Latin poet, was born at Naples. His father was also a poet, and Statius seems to have been trained as one from the start. Of events in the life of Statius we know little. From his boyhood he was victorious in poetic contests-many times at his native city Naples, thrice at Alba, where he received the golden crown from the hand of the emperor Domitian. But at the great Capitoline competition (probably on its third celebration in A D. 94) Statius failed to win the coveted chaplet of oak leaves. Perhaps the emperor's favour had failed him; in any case, he withdrew to Naples (Silv. iii. 5).

The rôle of court poet seems to have suited Statius. His flattery is as far removed from the gentle propitiatory tone of Opintilian as it is from the coarse and crawling humiliation of Martial. It is in the large extravagant style of a nature in itself healthy and generous, which has accepted the theme and left scruples behind In one of his prefatory epistles Statius declares that he never allowed any work of his to go forth without invoking the godhead of the divine emperor Statius had taken the full measure of Domitian's gross taste, and, presenting him with the rodomontade which he loved, puts conscience and sincerity out of view, lest some uneasy twinge should mar his master's enjoyment

As a poet, Statius unquestionably shines in many respects when compared with most other post-Augustans He was born with exceptional talent, and his poetic expression is, with all its faults. richer on the whole and less forced, more buoyant and more feheitous, than is to be found generally in the Silver Age of Latin poetry Statius is at his best in his occasional verses, the Silvae, which have a character of their own, and in their best parts a charm of their own The subjects of the Silvae are very various. Five poems are devoted to flattery of the emperor and his favourites, but of these enough has already been said. Six are lamentations for deaths or consolations to survivors Another group of the Silvae give picturesque descriptions of the villas and gardens of the poet's friends In the "Kalendae decembres" we have a striking description of the gifts and amusements provided by the emperor for the Roman population on the occasion of the Saturnalia In his attempt at an epithalamium (Silv , i, 2) Statius is forced and unhappy But his birthday ode in Lucan's honour (Silv, ii, 7) has, along with the accustomed exaggeration, many powerful lines, and shows high appreciation of preceding Latin poets Some phrases, such as "the untaught muse of high-souled Ennius" and "the lofty passion of sage Lucretus," are familiar words with all scholars

The epic poems of Statius are less interesting because cast in a commoner mould, but they deserve study in many respects. They are the product of long elaboration The Thebass, which the poet says took 12 years to compose, is in 12 books, and has for its theme the old "tale of Thebes"-the deadly strife of the Theban brothers There is also preserved a fragment of an Achilleis, consisting of one book and part of another. In the weary length of these epics there are many flowers of pathos and many little finished gem pictures, but the trammels of tradition, the fashionable taste and the narrow bars of education check continually

the poet's flight.

The edito princeps of the epics is dated 1470, of the Silvae 1472. Notable editions since have been those of Bernartius (Antwerp, 1593, Conowins (1633) and Barth (1664). Later texts are the Telephot (the Achileis and Thebas by Kohlmann, the Silvae by Bashrean) and that contained in the new cellular, the Silvae by Bashrean's and that contained in the new cellular (1648). Silvae by Bashrean's and the contained in the new cellular (1648) and Veillner (1588), the latter with an explanatory commentary. Among editions of positions of Statis' works, that of the Silvae by Malkland (1778) deserves special attention. A translation of the Silvae with introduction and notes was published by D. A. Stater in 1968 (Oxford Lafolties was been by O. Miller (Telephot). The Telephot of Translations). A translation of the Telephon and Achillers was been by O. Miller (Telephot). The Telephot of Translations of the Telephon and the Silvae (Telephot). The Telephot of Telephot (1648) and the Telephot of Telephot (1648) and the Telephot (1648) and

STATUE OF LIBERTY. See LIBERTY, STATUE OF.

STATUTE. A statute was defined by Sir Edward Coke as "an Act of Parliament made by the King, the Lords and the Commons," This definition is still apt in English law, save that in certain cases, provided for by the Parliament act, 1911, a bill may become an act even though the house of lords has not consented to it. The procedure for the enactment of statutes is regulated mainly by usage and the standing orders of parliament. Church assembly measures passed under the Church of England Assembly (Powers) act of 1010 and presented for the royal assent after a favourable resolution of both houses of parliament have the power and effect of acts of parliament. The earliest English statute is the Statute of Merton, 1235. Acts were engrossed upon the statute roll from the time of the Statute of Gloucester (6 Edw. I) but this practice has long been discontinued. Official copies of acts are now made on vellum and lodged at the public record office and in the house of lords. In the case of Church assembly measures, a third vellum copy is printed and sent to the Church assembly.

Classification of Statutes.—Acts of parliament are classified

as (1) public general acts; (2) local (or "local and personal") acts, including public acts of a local character; (3) private personal acts; (4) Church assembly measures (see above).

With the exception of certain classes of private personal acts (such as naturalization and divorce acts), which are virtually obsolete, all acts of parliament are printed by the queen's printer There are two separate series of volumes, one containing the public general acts and Church assembly measures, the other containing local and personal acts together with certain statutory orders (see below)

For the purposes of the law of evidence, however, a different classification applies, and by section 9 of the Interpretation act, 1889, every act passed after 1850 is a public act unless the act expressly provides to the contrary. Such acts are judicially noticed and no proof of them is required. Acts which are stated not to be public acts are usually provable by the production of a queen's printer's copy.

Acts may also be classified according to their object by such terms as penal, beneficial, imperative, directory, enabling, disabling, taxing, codifying, consolidating, perpetual, temporary and so forth This last classification is important for the purposes of

interpretation (see below).

Penal acts are those which impose a new disability; beneficial, those which confer a new favour An imperative statute (often negative or prohibitory in its terms) makes a certain act or omission absolutely necessary, and subjects a contravention of its provisions to a penalty A directory statute (generally affirmative in its terms) recommends a certain act or omission, but imposes no penalty on nonobservance of its provisions. To determine whether an act is imperative or directory the act itself must be looked at, and many nice questions have arisen on the application of this rule of law to a particular case Enabling statutes are those which enlarge the common law, while disabling statutes restrict it Declaratory statutes, or those simply affirming the common law, once not uncommon, are now practically unknown, the Treason act is an example Statutes are sometimes passed in order to overrule specific decisions of the courts Examples are the Territorial Waters Jurisdiction act, 1878, the Married Women's Property act, 1893, and the Trade Disputes act, 1906

Every act has a short title by which it may be cited; e.g., the

Transport act, 1953.

Interpretation of Statutes.—The Interpretation act, 1889, provides an authentic interpretation for numerous words and phrases of frequent occurrence in statutes Moreover, most modern acts contain an interpretation section which explains particular expressions in that act. The main body of the law on this subject is, however, to be found in judicial decisions, i e, the common law The main rules are as follows: (1) The meaning of an act is primarily to be sought in the act itself. (2) The words of an act are to be construed in their ordinary and natural sense, unless in the case of particular expressions there is something to the contrary in the context or in the scheme of the act. (3) The act is to be construed as a whole and acts in pari materia are to be construed together as forming one system. (4) Contemporaneous circumstances may be taken into account where the intention of the legislature cannot otherwise be ascertained. What is known as the rule in Heydon's case (1584) (3 Coke Rep., 7a) provides that the factors to be ascertained in this connection are (a) what was the common law before the act; (b) what was the mischief or defect for which the common law did not provide; (c) what remedy parliament has resolved and appointed to cure the disease, and (d) the true reason for the remedy. (5) Where words can be interpreted in two different ways the inconvenient, unjust or absurd consequences of adopting the one way may guide the court to adopt the other. (6) The full title and the preamble but not the short title, heading or marginal note may be used for the purpose of interpreting the act as a whole, or in order to resolve any ambiguity. (7) Acts which purport to interfere with existing rights must be clearly expressed. (8) Statutes are to be so interpreted as far as their language admits as not to be inconsistent with the comity of nations or with the established rules of international law. (9) Some acts are, to be liberally or benevolently construed, others strictly. Instances of those which fall into the former category are acts which are remedial, amending; explanatory; for the maintenance of religion,

the advancement of learning and the relief of the poor, directory as distinguished from mandatory or imperative enactments; and those in favour of the liberty of the subject. The acts to be strictly construed include those restricting the liberty of the subject; penal acts, fiscal and revenue acts; acts creating statutory powers and duties; private acts; acts affecting the prerogative of the crown, existing private rights or the jurisdiction of the courts In the case of penal statutes, for instance, strict construction means that the thing charged as an offense must be within the plain meaning of the words used, and must not strain the words on any notion that there has been a slip, that there has been a casus omissus, or that the thing is so clearly within the mischief in the mind of the legislature that it must have been intended to be included and would have been included if thought of. Great care must be taken not to extend penal laws beyond what the legislature has clearly meant and adequately expressed Similarly in the case of taxation statutes the court is not to be guided so much by the objects which it thinks such acts are to achieve, as by considering whether the words of the act have reached the alleged subject of taxation. There is no presumption as to a tax; nothing is to be read in; nothing is to be implied One can only look fairly at the language used. (10) Codifying and consolidating acts give rise to an inference that it is intended to reproduce the existing position and not to alter the law. A codifying act is, however, in the first instance, to be looked at without reference to the previous law if it is unambiguous, whereas reference is to be made to the previous law to ascertain the intention of the legislature in the case of an amending or consolidating act. (11) In construing acts, such as taxing acts, which apply to both England and Scotland, it is well settled that a construction should, if possible, be adopted which will make the incidence of taxation the same in both countries, (12) A special act which imposes mutual obligations on several parties so that it has a contractual operation should as between parties be construed in the same way as a contract to the same

Operation of Statutes.—The date of the "passing" of an act is the date when it becomes law. This is the date when it receives the royal assent This date is also, in the absence of a provision to the contrary, the date of the "commencement" of the act; i.e., the date when its provisions come into effect

An act of the United Kingdom parliament is to be construed prima facle as applying to the whole of the United Kingdom and not to any place outside. The United Kingdom does not include the Channel Islands or the Isle of Man.

An "extent" or "application" clause will, however, vary the effect of this rule. Acts are extended to apply to waters adjacent to the United Kingdom and other parts of her majesty's dominions for certain purposes For the application of statutes outside the United Kingdom, see below.

An act generally applies only to those within the allegiance of the crown and does not extend to foreign subjects out of the queen's dominions. An act applicable to the queen's dominions is, if the context permits, to be construed as applying to all British subjects wherever they may be.

It is a clear rule of law that the crown is not bound by an act of parlament, unless it is expressly named or clear words of implication are used. The crown for this purpose includes the great departments of state, but bodies such as the British Transport commission have been held not to be the servant or agent of the crown for this purpose. The crown may, however, be held to be bound by implication if it be hencenet purpose of the act would be otherwise wholly frustrated. The crown is, however, entitled to the benefit of an act although not named.

Generally speaking the courts will hold that statutes are not retrospective, if it is possible so to construe them. This fundmental rule of English law involves another to the effect that a statute is not to be construed so as to have a greater retrospective operation than its language renders necessary. Where an act is repeated the repeat does not in general affect its previous operation.

The provisions of a public act can be overridden or varied only by express enactment or clear implication. Where the common law is to be changed, and especially the common law which a statu-

tory provision has secognized and enforced, the intention of any new enactment to abrogate it must be plain to exclude a construction by which both may stand together. Similarly, existing rights are not destroyed by a statute unless there are express words or the plannest implication to that effect. The principle applies whether the rights be common law rights, rights of action, rights of wordership or rights snanng under a contract. Again, the jurisdiction of the superior courts over matters originally cognitable by them cannot be taken away except by express words or necessary implication. On the other hand, it has been settled for a long time that the creation of a right of appeal is an act requiring legislative au-

Temporary acts may be made perpetual or may be continued from time to time The latter is now achieved largely by periodic Expiring Laws Continuance acts The Army and Air Force acts are instances of temporary acts specifically re-enacted annually

Enforcement of Statutes—Crimes created by statute are tried either summarily or by indictment and there are some which are tried by courts, such as courts-martial, having jurisdiction over a hinted class of persons. Again, a breach of a statutory command in a matter of public concern is indictable at common law, and in the absence of a special statutory remedy the performance of a public duty may be enforced by indictment or by information filed the threach may be entired by indictment or by information filed the breach may be granted in appropriate as continuates of mandanus lies for the enforcement of a public duty provided there is no more appropriate.

In some cases a person dammified by a breach of statutory duty may bring proceedings to recover his loss. This holds only where no remedy for the breach by way of penalty or otherwise is prescribed, or where it appears that the duty is imposed for the benefit of particular persons.

The operation of an act may be suspended by a subsequent statute. Many instances of this occurred during World War II by means of emergency legislation. Similarly, an act may be repealed or amended by a later act. Repeal by implication may occur where the provisions of a later enactment are repugnant to the earlier, but such repeal is never to be favoured. An act in its application to England cannot be repealed by non-user (see below as to Scotland). There is a presumption that, where special statutory provision has been made for a specific class of cases, a subsequent general enactment is not intended to interfere with such provision. The Interpretation act, 1889, contains many provisions relating to

legislate Legislation.—Modern statutes tend increasingly to provide that a particular authority shall have power to make ortunder that a particular authority shall have power to make ortunder that act. Power may read to operate the matter at rain under the act. Power may not provide the control of the con

Scotland.—Much of what has already been said applies to Scotland has big it must be emphasized that Scotland has its own courts whose decisions are often quite different from those of the English courts. A public general statute applies generally to Great Britain and Northern Ireland, which includes Scotland, unless otherwise stated. By the Private Legislanto Procedure (Scotland) act, 1936, which applies to Scotland only, where any public authority or persons desire a private act they may apply to the secretary of state for Scotland for a provisional order. In the absence of any opposition the secretary of state for Scotland is directed to introduce into parliament a confirmation bill, and any resulting act is a public act for parliament.

In the 17th and 18th centuries the court of session promulgated acts of sederunt amounting to general legislation. In modern times

these acts relate exclusively to procedure and are usually passed in virtue of a specific authority in some particular statute. In 1943 an act of sederant approved new consolidated rules and repealed the provisions of any previous act inconsistent with them. An act of adjournal is an act passed by the high court of justiciary for regulating procedure in that court and in inferior criminal courts.

A statute may be impliedly repealed by falling into desuctude. This rule is not applicable except to Scots acts, i.e., those passed before 1707. There is no analogous principal in England, and even in Scotland no statute passed after the union in 1707 has been held by the Scottish courts to have fallen into desuctude.

Scots acts, which are usually expressed briefly and without detailed provisions, have been interpreted in a very liberal spirit. In their construction it is a recognized rule that, whatever the literal meaning of the statutory words, they are to be read as interpreted by decisions pronounced shortly after the act was passed Apart from this important difference, the rules of interpretation in Scotland are similar to those decisions of the properties of the properties of the state of the s

Northern Ireland.—The parlament of Northern Ireland consists of the queen, the senate of Northern Ireland and the house of commons in Northern Ireland. The Government of Ireland act, 1920, edals with Egislation in Northern Ireland and gives power to make laws for the peace, order and good government of Northern Ireland with certain matters reserved to the United Kingdom parliament. Parlament at Westminster does not as a matter of practice legislate for Northern Ireland un matters within the jurisdiction of the Northern Ireland parlament although it has power to do so

British Dominions, Colonies and Dependencies.—Acts of the imperial parlament do not extend to dominons, colonies or dependencies unless these are specially named therein. Moreover, the United Kingdom parliament cannot legislate for the self-governing dominions without their onsent. Colonies are either self-governing dominions. By the Colonial Line velf-governing of crown colonies. By the Colonial Line velf-governing of crown colonies. By the Colonial Line velf-governing or crown colonies. By the Colonial Line velf-governing the properties of any act of parliament extending the repugnant to the provisions of any act of parliament extending law is to be voud by repugnancy to the law of England unless it is repugnant to such an act of parliament For colonies without representative legislatures the crown usually legislates. The relationship between the United Kingdom parliament and the dominion legislatures is dealt with by the Statute of Westminster, roas:

Other Countries.—In most other countries, with the exception of the United States (see below), there is a code of law. The assent of two chambers and of the head of the state is generally necessary to legislation.

The term "statute" is used by international jurists to denote the whole body of the municipal law of the state. In this sense, statutes are either real, personal or mixed. A real statute is that part of the law which deals directly with property, whether movable or immovable. A personal statute has for its object a person and deals with questions of status such as marriage, legitimacy and infancy. A mixed statute affects both property and persons and it is said to deal with acts and obligations. Personal statutes are of universal validity; real statutes have no extractritorial authority. (See also Acr or Parliament, Parliament, (F. E. L.)

## UNITED STATES

"Statute" in U.S. law is generally confined to an act of the legislature, though the term is occasionally used to apply to municipal ordinances and the rules and regulations of administrative agencies passed in the exercise of delegated legislative functions. The concurrence of the executive is demanded for the efficacy of the legislative act. The executive is accorded a veto over legislature action which can, however, be overridden by concurrence of a sufficient majority in the houses of the legislative action which can, however, be overridden by concurrence of

Any consideration of statute making in the United States must bear in mind the federal character of the nation. Not only does each of the states possess statute-making powers for that state, but the national government within the ambit of its delegated powers may pass statutes effective throughout the nation. The

device of judicial review over legislation is the scheme by which conflict between the various statutes is resolved. As the supreme law of the land stand the constitution, treaties and laws of the United States, and state statutes passed in contravention of them are unenforceable. Not only are state and the lower tederal courts obliged to refuse to enforce a state statute contravening federal constitutional or statutory law, but, by providing for an appeal to the US supreme court, the validity of state statutes can be brought for judgment to that ultimate tribunal. The supreme court thus occupies the position of arbiter in the eternal conflict between states and nation State statutes must also comply with the provisions of the state constitution but the final arbiter of their compliance is the state supreme court and not the U S supreme court (See Constitution and Constitutional Law.) State statutes in violation of the state or federal constitution are void, but state statutes contravening federal statutes are suspended during the operation of the latter

The fact that there are many different statute-making bodies in the United States makes for an immense mass of legislation Despite the fact that most state legislatures have only breintal sessons, their legislative activity produces a vast number of statutes. The first thorough attempt to keep in buch with their activity by mechanism of an index to state legislation was originated in 1938 by the Library of Congress. Periodic revisions of their statutes are made by each state but upon plans that lack any unformity. No revision of the statutes of the federal government was made until 1847. Thereafter, several there were published.

Statutes commonly take effect from the date that they receive the executive assent. In some states constitutional provisions prescribe that they shall not be effective until after the expiration of a certain time after their passage, unless the legislature shall designate that the matter is one of such public urgency as to require their immediate operation. The result of these restrictions has been simply to induce the legislature to append an urgency clause to each statute irrespective of its subject matter. Two other common constitutional provisions deserve notice. To avert the process of Togerolling for the inclusion of particular legislation that the process of Togerolling for the inclusion of particular legislation deal with more than one subject, to be plainly and specifically expressed in the life to the act.

The complexity of federal and state legislation focused attention on the development of means to improve the quality of statutory law. Since legislative drafting requires special qualifications, the federal and many state governments provide specially trained legislative counsel to prepare measures. In addition to technical problems of drafting, the substantive aspects of legislation are matters of concern. For example, under the Legislative Reorganization act of 1946, important committees of the congress were provided with professional staffs to do research In other instances, commissions aided by experts prepare particular statutes such as codes of procedure, workmen's compensation laws and tax measures. Continuity of legislative policy is sometimes attained through the device of the legislative council. In recognition of the need for the constant scrutiny of legislation to keep the law abreast of current problems, the state of New York created a law revision commission in 1934, charged with the duty of continuously revising the statutes.

A movement toward uniformity in state statutory laws was initiated by the organization of the Commissioners on Uniform State Laws in 1892. Commissioners appointed by each state meet analyt to frame legislation on subjects upon which uniformity is believed essential and recommend its enactment by state legislatures. Their most successful achievements were in the field of commercial law, though their endeavours embraced subjects of wide variety. The Council of State Government prepares legislation in areas of general interest, not necessarily for enactment in uniform style but for the purpose of suggesting models to guide particular state legislatures. Other efforts to promote uniformity have been midde by praviate interest groups and public welfare organizations. Interpretation statutes upon the British model were also enacted in some states, atthough they have been of doubtful

Another peculiar American problem relates to the extent to which courts take cognizance of statute law. All courts are bound to take judicial notice of the federal laws and the statutes of the state in which sail is brought. But different doctrines are in force as to the extent to which they will take notice of the statute law of other states. In many states statutes require the courts to take notice of such laws. In others they must be specially pleaded or proved or the courts will assume that the law of the other state is identical either with their decisional or statutory law. After 1936 most states adopted the Uniform Judicial Notice of Foreiga Law act requiring judicial notice of the common and statute law of other states but not other countries.

Statutes have different forms, being either acts of the legislature or joint or concurrent resolutions of both houses of the legislature or joint or concurrent resolutions of both houses of the legislature Treaties of the national government have the force of statutes and stand on a parity with them. Like statutes they are the "supreme law of the land" and supersede conflicting state legislation. Just as a subsequent statute may repeal an earlier on, a later statute repeals an earlier treaty. States are forbidden to conclude treaties but may make compacts with one another with the assent of congress. Such compacts also have the effect of statutes. They have been used to deal with problems that demand a regional treatment greater than a single state can give and yet less than is desirable for nation-wide control.

Codification of the law in the European sense has been periodically urged in the various states since 1848, when the Field code was adopted in New York. This code attempted to recognize and simplify procedural law. A proposed codification of substantive law was not enacted Procedural and substantive codes were, however, adopted in numerous states That the hope-for results of simplifying and clarifying the law have not been realized was attributable, perhaps, to the unwillingness of judges to treat codes as ultimate sources of the law, as is done by those trained in the civilian legal system. Limited attempts to codify certain segments of the law met with more success. The restatements of the law by the American Law institute were somewhat analogous to codes and were undertaken for similar purposes but were not adopted as statutes.

STAUNTON, HOWARD (1810-1874), English Shakespearian scholar and writer on chess, supposed to have been a natural son of Frederic Howard, 5th earl of Carlisle, was born in 1810.

Settling in London, he soon spent the small fortune left him under his father will and began to make his living by journalism. He gave much of his attention to the study of the English dramatists of the Elizabethan age. As a Shakespearian commentator he showed the qualities of acuteness and caution which made him excell in chess. He possessed, moreover, a thorough mastery of the literature of the period, shown in his papers in the Athenaeum on "Unsuspected Corruptions of Shakespeare's Text," begun in Oct. 1872. These formed part of the materials which he intended to utilize in a proposed edition of Shakespeare which never became an accomplished fact.

In 1864 he published a facsimile of the Shakespeare folio of 1623 and a facsimile edition of *Much Ado About Nothing*, photolithographed from the quarto of 1600.

Staunton died in London on June 22, 1874. Staunton's services to chess literature were very great, and the game in England owes much of its later popularity to him. For his important works on the subject 596 CHESS.

STAUNTON, a city of Virginia, U.S., 1,385 ft. above sea level, in the heart of the beautiful and fertile Shenandoah valley, 210 ml. N.W. of Richmond, the county seat of Augusta county, but administratively independent of it. It is at the intersection of ideral highways 11 and 250 and is served by the Chesapeake-Western and the Chesapeake and Ohio railways Pop (1930) 19,997 (1985, Negroes) by federal census It is a city of beautiful residences and numerous schools and institutions, including two state mental hospitals

The former ministers' home or manse of the First Presbyterian church, birthplace of Woodrow Wilson, was dedicated as a national shrine in 1941. About 20 mi. S. of the city is the homestead of

Cyrus McCormick, where he invented the reaper

Within 50 mi are five great caverns, Natural bridge, Natural chinneys, the George Washington National forest and the Shenandoah National park, which is traversed for its entire length by the Skyline drive. In the city are antional cemetry and a large Confederate cemetery. Staunton was the first city in the United States to adopt the city manager form of government, in 1908. There are large textile, hosiery, furniture, lumber and flour mills located in and near the city.

The first settlement in the vicinity was made in 1731, 2 mi E of the present city A county courthouse was bull in 1745, and the name Staunton (the family name of the wife of Sir William Gooch) was adopted about 1748. In 1751, when Colonel Tarleton drove the general assembly of Virginia across the Blue ridge, it took refuge there, holding its sessions for a time in the old Trinity Episcopal church. During the Civil War Staunton was an important supply base for the army of northern Virginia and for Jackson's Valley campaign, and it was twice occupied by Federal troops. It was chartered as a city in 1870.

STAUROLITE, a mineral consisting of basic aluminum and ferrous iron slineate with the formula HFebAjshofa. The material is, however, usually very impure, the crystals enclosing sometimes as much as 30% or 40% of quants and other minerals as well as carbonaceous matter. Crystals are orthorhombic and have the form of six-saded prisms. Interpenentaing cruciform twinned crystals are very common and characteristic, they were early known as pierress de crois or laphs crussifer, and the name "staurolite" has the same meaning (Greek, σταμός, a cross, and Milora, stone). In fig. it the twin plane is (302) and the two prisms intersions.

FIGS. 1 AND 2.-TWIN CRYSTALS OF STAUROLITE

cross at an angle of 9x° 2x'; in fig. 2 the twin-plane is (232) and the prisms intercross at nearly 6o°. The mineral is translucent to opaque and dark reddish brown in colour. Waterworn pebbles of material sufficiently transparent for cutting as gem stones are occasionally found in the diamantiferous sands of Brazil. The hardness is 75, specific gravity 375. Staurolite is a characteristic mineral of crystalline schists, and it is also a product of contact-metamorphism. It is found at various points in Virgina, North Carolina and Georgia embedded in schist or weathered loose in the soil, often as fine twinned crystals that are prized as good luck charms (fairly stones).

STAVANGER, a seaport of Norway, capital of Rogaland yike (county), on the west coast on the Bukken four? Pop. (1946) 49,173. The town is one of the oldest in Norway, founded in the 8th or ofth century, but the greater part of the present own is modern and built of stone. It became the seat of a bishoppir in the 13th century, and though the see was removed to Christian-

sand in 1685, it was restored in 1925 The cathedral church of St Swithun, founded by the English bishop Reinald at the end of the 11th century, and rebuilt after being burned in 1272, 18, next to the cathedral of Trondheim, the most interesting stone church in Norway The old episcopal palace of Kongsgaard is now a Latin school The fisheries are important-for herring, mackerel, sprats, cod, salmon, lobsters and anchovies. The extraoidinary growth of Stavanger was mainly due to its fish-canning industry Other industries are the making of jodine from seaweed.

and shipbuilding It was occupied by Germany in April 1940 STAVELEY, town and urban district of Derbyshire, England, 12 mi SE. of Sheffield, on the LMS and LNE railways Pop (1951) 17,941 Area, 10 2 sq mi The ancient church of St John the Baptist contains a 12th century font Staveley hall. formerly the home of the Frechevilles, was built in 1604 and is

now the rectory. Coal mining is the dominant industry, though there is also an

old established brush manufactory

STAVELOT, town on the Amblève, province of Liége, Belgium. Pop (1939) 4,792. Here Charles Martel gained a signal victory over Neustria in 719 The prince-abbot of the monastery of Stavelot (established 7th century) exercised secular authority over many towns in the Amblève and Warche valleys, including Malmédy, and had a seat in the old German Diet

STAVROPOL, a former province of Russia, now in the Caucasian Area, North (q v)

STAVROPOL, a town of Russia see Voroshilovsk.

STAWELL, a municipality of Borung county, Victoria, Australia, 179 mi by rail W N W of Melbourne. Pop. (1947) 4,840 The quartz reefs of the Pleasant Creek goldfields near by are worked at very deep levels and there are cyanide plants, It lies near the Wimmera river just north of the Grampian and Pyrenees plateaus, in an important sheep and fruit district

STEAD, WILLIAM THOMAS (1849-1912), English journalist, was born at Embleton, Northumberland, on July 5, 1849, the son of a Congregational minister He was early apprenticed in a merchant's office at Newcastle-on-Tyne; he soon graviassistant editor of the Pall Mall Gazette under John Morley, and when the latter retired he became editor (1883-1889). 1885 he had distinguished himself for his handling of public affairs, and his brilliant modernity in the presentation of news. He introduced the "interview," made a feature of the Pall Mall Gazette "extras," and his enterprise and originality exercised a potent influence on contemporary journalism and politics

In 1885 he entered upon a crusade against vice by publishing a series of articles on the "Maiden Tribute of Modern Babylon" Though his action undoubtedly furthered the passing of the Criminal Law Amendment act, it made his position on the paper impossible; and he was imprisoned in Holloway jail for three months on a charge arising out of his crusade On leaving the Pall Mall Gazette he founded the monthly Review of Reviews (1890)

He started cheap reprints (Penny Poets and Prose Classics, etc), conducted a spiritualistic organ, called Borderland (1893-1897), in which he gave full play to his interest in psychical research; and became an enthusiastic supporter of the peace movement, and of many other movements, popular and unpopular. He wrote with facility and sensational fervour on all sorts of subjects, from The Truth about Russia (1888) to If Christ Came to Chicago (1893), and from Mrs. Booth (1900) to The Americanization of the World (1902). In private life his keen sense of merit and kindly interest influenced many aspirants to journalism and literature

Stead went down in the "Titanic" on April 15, 1912. See Life of W. T. Stead (1913), by his daughter; and F. Whyte, Life of W. T. Stead (1925).

STEAM, the vapour of water. In the pure state it is a dry invisible gas Often, however, as in a jet escaping from the spout of a kettle or the funnel of a locomotive, it is mixed with minute particles of water which are produced by condensation of portions of the gas. In such a mixture the suspended particles of water

constitute a visible cloud Any mixture of steam with water, whether in such a cloud or in the working chamber of an engine or turbine, is often spoken of as wet steam.

Its properties are most conveniently described by imagining an experiment in which steam is formed by applying heat to a small quantity of water contained at the bottom of a large upright cylindrical vessel Suppose that the vessel is fitted with a piston which rests on the water to begin with and can rise when the fluid below it is made to change from water into steam by applying heat. Imagine further that the piston is frictionless and carries a definite weight so that, as the piston rises, the fluid continues to be subjected to a constant pressure, say, p lb per square inch

Saturated Steam .- When heat is applied, no steam is formed until the temperature of the water is raised to a value T which depends on p Steam then forms, raising the piston, and this goes on without further rise of temperature until all the water is converted into steam, when it occupies a certain volume V During this stage the steam is said to be saturated T is the temperature of saturation corresponding to the pressure p, and is the lowest temperature at which steam can exist in stable equilibrium at that pressure

Superheated Steam.-Suppose now, after all the water has turned into steam, that we go on applying heat. The temperature will rise and the volume will increase beyond V if we keep p constant, or the pressure will increase beyond p if we then fix the piston so as to keep V constant. In either case the steam is said to be superheated.

Steam is superheated when its temperature is raised in any manner to a value which exceeds the temperature of saturation corresponding to the actual pressure. Thus for example steam may change from the saturated to the superheated condition by being compressed (without loss of heat), or by passing (without loss of heat) through a throttle valve into a region of lower pressure When steam is so "throttled" its temperature falls to some extent, but remains higher than the temperature of satura-

tion corresponding to the reduced pressure Properties of Steam: Callendar's Tables.-The physical tated, however, into journalism, and in 1871 became editor of Properties of Steam: Callendar's Tables.—The physical the Darlungton Northern Echo. In 1880 he went to London to be properties of steam have been the subject of systematic experimental enquiry by Regnault and many later observers. Our modern knowledge of them is largely due to H. L. Callendar who, with the help of formulas the basis of which is partly theoretical and partly empirical, has rationalized the experimental data and has compiled comprehensive tables for the use of engineers Callendar's tables, published in 1915 and in an enlarged form in 1924, set forth all the important properties throughout a suitable range of pressures and temperatures From the principles of thermodynamics (q v.) it is known that certain relations hold between various properties, in steam or any other vapour, the values stated by Callendar, besides being founded on the best available data, are consistent with these relations. They apply to the superheated as well as to the saturated state; saturation is to be regarded as only a limiting case.

So long as steam is saturated the relation of temperature to pressure is definite But steam may be superheated to any temperature above the saturation temperature at which it is formed in the boiling of water, and the temperature then becomes an independent variable. This affects certain other properties with which the steam engineer is concerned, namely .-

The volume V, The internal energy E, The total heat I. The entropy φ,

all of which are to be reckoned per lb of the substance Each of these quantities has a definite value for steam or for water in any assigned state of pressure and temperature. Steam tables usually follow a convention, according to which quantities such as the energy or the entropy are treated as zero for water at o° C: the tabulated numerical value accordingly expresses the amount by which the quantity in question has changed when the substance passes from that zero condition to the actual state.

Internal Energy.-When steam is formed (starting, say, from

work is done by the expansion of the substance The difference, which depends simply on the final state and not on the manner of formation, is called the internal energy E

Total Heat.-The total heat I is conveniently defined by the equation

$$I=E+APV$$

where P and V are respectively the pressure and volume of the substance, and A is a factor which converts units of work into units of heat Hence when the substance is heated under constant pressure the change of I is measured by the quantity of heat that is taken in, for it is then equal to the gain of internal energy plus the work done. In a process of throttling it is easy to show that I does not change, provided there is no loss of heat to other bodies

Entropy.-To define entropy, it may be said that when the substance takes in heat in a reversible manner (namely a manner which excludes the existence of any turbulent movement) its entropy changes by the amount  $\frac{Q}{T}$  where Q is the heat taken in and T is the temperature (on the absolute scale) at which it is taken in If T is itself changing while the heat is being taken in, we must write this change of entropy as  $\int \frac{dQ}{T}$ · Thus when steam is formed in a quietly steaming boiler, at a constant temperature T, from water at the same temperature, the entropy  $\phi$  changes by the quantity  $\frac{L}{T}$  , where L is the "latent heat." Like the other quan-

tities, the entropy of water at oo C is reckoned as zero for convenience in tabulation Both the entropy of steam and the total heat are quantities of great importance in the theory of the steamengine (q.v.)

Critical Temperature .- Imagine a quantity of superheated steam at any usual temperature to be compressed while the temperature is kept constant. When the pressure reaches a certain value condensation begins, and we are then dealing with a substance which is partly water and partly saturated steam. The pressure in question is that which corresponds to saturation at the assumed constant temperature This pressure will not rise further until all is condensed after that the pressure on the water may of course be increased to any extent. The process is discontinuous, with three distinct stages. Suppose this experiment to be repeated at various temperatures: it will be found that when the temperature is sufficiently high there is no stage during which both water and steam are present together When this temperature is reached or exceeded, the substance passes, as its pressure is increased, from the condition of steam to that of water-from vapour to liquid-in a continuous manner without ever being a mixture of the two The lowest temperature at which this can happen is called the critical Temperature, and the limit of pressure above which the substance cannot exist as a non-homogeneous mixture of liquid and vapour is called the critical Pressure. These conditions of pressure and temperature constitute the "critical point" The critical temperature of steam is about 374° C and the critical pressure about 3,158 lb. per square inch.

The properties of steam in the neighbourhood of the critical point are less exactly known than at lower and more usual pressures. The "characteristic equation" on which Callendar founds many of his tabulated values applies with sufficient exactness within the lower range of pressures commonly met with in engineering practice. It takes the form

$$V = \frac{RT}{P} - c + b$$

where V is the volume (per lb ), T is the absolute temperature, P is the pressure, R is a constant relating to the ideal volume of a gas, b is a constant which expresses the additional volume of the molecules, and c is a term, depending on the temperature, which expresses the loss of volume through "coaggregation" or temporary association of molecules. The equation is applicable to the superheated as well as the saturated state,

Super-saturation.-When steam is cooled to a temperature at

the state of water at o° C) heat is taken in, and some external which condensation should occur, it is found, when no nuclei are present about which water droplets may form, that the temperature may fall some way below the temperature of saturation before condensation begins A temporary and unstable state may accordingly be produced, called super-saturation The vapour in this condition may be described as supercooled its state is analogous to that of a liquid cooled below its melting point without crystallization

Water-vapour in Air .- Water vapour is one of the constituents of the atmosphere, the proportion depending not only on the temperature but on other causes which affect local dryness At any given temperature air is said to be saturated with water vapour when the proportion present is such as to exert a partial pressure equal to the pressure of saturation corresponding to the given temperature Any excess tends to be thrown out as mist or rain any less quantity than that required for saturation is held as an invisible constituent, namely, in the state of super heated steam The quantity of water-vapour present in air may be expressed as a fraction of the quantity which would cause saturation this fraction is called the "relative humidity" of the air The "dew-point" is the temperature to which air must be cooled to allow a deposit of water to take place

Air is often dried for industrial uses by cooling it to a very low temperature This causes it to deposit nearly all its contained moisture, which is then drained away, leaving only the triffing quantity that suffices to produce saturation at the low temperature When the air returns to normal temperature without taking up more water its relative humidity is very small

See Regnault, in Mém. Inst. France (1847, Vol. XXI); H. L. Callendar, Properties of Sleam (1920), and The Callendar Steam Tables (1915); J. A. Ewing, Thermodynamics for Engineers (1920) (IAE)

STEAM ACCUMULATORS are devices for equalizing steam flow and steam demand They are inserted between the source of steam supply and the point where it is used for the purpose of absorbing steam at times of low demand and releasing it when needed; several types have been developed. One of the earliest was the Rateau accumulator or regenerator Its primary purpose was to utilize the intermittent exhaust from prime moverssuch as steel rolling-mill engines-for driving low-pressure turbines carrying a fairly constant load; installed in the steam line between these two units, it served to equalize supply and demand, the turbine governor being designed to admit live steam when necessary Another type is the Smoot accumulator, designed primarily for use in gas manufacturing plants. It collects, or accumulates, in a steel tank the exhaust from pumps and auxiliaries and from the

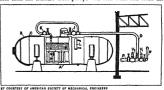

Fig. 1.-MECHANICAL DRAWING OF A COMPLETE ACCUMULATOR IN-STALL ATION

hot-water drips; by decreasing the pressure in this tank steam is made available for the intermittent operation of the water-gas apparatus, and deficiency in supply is taken care of by a live steam "make-up" valve The latest development is known as the Ruths steam accumulator, and while it operates on the same general principle as the others, it has been applied over a wider field of usefulness. Specially designed governor valves make its operation entirely automatic up to 200 lb, per sq in, and through greater pressure ranges (fig 1). The tank A is filled with water to 90% of its capacity, and the regulating valves V-r and V-2 automatically control the charging and discharging of the accumu-

lator The accumulator must be placed between the high and the low pressure steam line, and its pressure varies between these limits, accumulated steam is made available by the regulating valves in such a way as to maintain uniform steam pressures in the low pressure steam lines Any steam generated by the boilers and not used by the high pressure consumers overflows through valve V-r into the accumulator V-2 maintains a uniform pressure in the line P carrying the low pressure steam, so that if the valve V-1 is passing more steam than is required in the low pressure line, the excess is stored in the accumulator. Charging nozzles G are equipped with circulating pipes H which permit a uniform and noiseless heating of the water Should a sudden demand for high pressure steam arise the boiler pressure would drop slightly, V-1 would close and a certain amount of steam would become available at or near this higher pressure. This diversion to the high pressure line of steam intended for the lower pressures would cause a deficit in the low pressure line. V-2 would then open and the heat energy previously stored in the accumulator would instantly flash into steam to meet this deficit. Should the sudden increase in demand be caused by low pressure consumption and the flow through V-1 not sufficient, the accumulator would sup-(R A L) ply it.

STEAM-CHEST is a box cast on or attached to the sade of a steam cylinder, and contraining the side-valve which slides over the steam and exhaust ports, and uncovers these in turn A stuffingbox maintains the valve-rod steam-tight Some engines have two valves, one sliding upon the top of the other, for the purpose of gying expansive working of the steam Cylinderical or piston valves are used extensively in marine and locomotive cylinders, as they give a balanced effect all around in locomotive practice these valves have to be placed above the cylinders in many cases for reasons of design

STEAM COAL: see COAL AND COAL MINING.

STEAM ENGINE. A steam engine is a heat engine in which the working substance is steam By a heat engine is meant a machine for doing mechanical work through the agency of heat: it does this by taking in heat at comparatively high temperature, converting part of the heat into another form of energy, and rejecting the remainder of the heat at a lower temperature. The working substance is the vehicle by which heat is taken in and rejected In a steam engine, the substance takes in heat mainly in a separate vessel-the boiler-in the process of being vaporized: it does work by expanding under pressure and thereby converts part of the heat that is taken in; finally the remainder of the heat is rejected, either by allowing the steam to escape into the atmosphere, as in locomotives, or by condensing it at a comparatively low temperature and pressure, as in marine and many other engines. This gives a broad distinction between non-condensing and condensing steam engines. The latter have the great advantage that they allow the effective expansion of the steam to be carried much farther; the substance rejects heat at a lower limit of temperature, and this enables the engine to convert into work a larger fraction of the heat which it has received. That fraction expresses what is called the efficiency of the engine as a contrivance for converting heat into work. The addition of a condenser, while it increases the efficiency, of course complicates the mechanism: it requires a supply of cooling water or some equivalent means of keeping down the temperature by absorbing the heat which the steam gives up in the act of being condensed, and also a pump or other means of removing the condensed substance together with any air that may be present. But the advantage which it brings about in respect of efficiency is so great that all engines of large power, where economy of fuel is an important factor, and where the use of a condenser is practicable, are of the condensing kind.

Given the upper limit of temperature, at which heat is taken in, the efficiency which the engine may attain is determined by the lowness of the temperature at which heat is rejected. Similarly, when the lower limit of temperature, at which heat is rejected, is assigned, the efficiency which the engine may attain is increased by raising the temperature at which the working substance takes in heat. To secure high efficiency there must be a

wade range through which the temperature of the working substance talks, as a consequence of expansion within the engine, from the level of temperature at which heat is received to the level at which heat is rejected. Thus in the steam engine the most efficient performance, that is to say the greatest output of work in relation to the heat supplied, is secured by keeping the condenser as cold as the available cooling water will allow, and at the same time using a high bolier pressure, so that the working substance is very hot while it receives heat in the act of charging substance is very hot while it receives heat in the act of charging outwarders are to seem for the pressure, as the mechanical difficulties of boiler construction and high pressure working are overcome.

After conversion into steam the working substance may take in a supplementary supply of heat on its way from the boiler to the engine, by passing through a superheater, in which its temperature is raised above that of the boiler A common form of superheater is a group of parallel piose with their surfaces

exposed to hot gases of the boiler furnace

Steam engines are classified into two general types according to the manner in which the steam does work during its expansion. In the first, or piston-and-cylinder type, the steam, in a confined space, namely the part of the cylinder behind the piston, enlarges the volume of that space by pushing the piston forward. It does work by exerting a static pressure on the moving piston, the movement of the steam itself is of no significance. In the second class, to which belong all kinds of steam turbines, the action is less direct. The pressure of the steam is first employed to set the steam itself into motion, forming a let or group of iets, the momentum of which causes work to be done on a moving part of the machine, either by the impulsive action of the jet or jets on revolving vanes, or by the reaction on revolving guideblades during the formation of the jets, or, as in Parsons bine, by a combination of impulse and reaction. In any turbine the action of the steam is kinetic, in contrast with its static action m an engine of the piston type In both types there is progressive expansion of the steam from the high pressure and relatively small volume at which it is admitted, to the low pressure and relatively very great volume at which it is discharged. The principle already stated, that a large range of temperature and pressure, between admission and exhaust, is essential to efficiency applies equally to both types. In practice, the turbine has a notable advantage over the piston-and-cylinder engine in this respect, that it allows the last stages of the expansion, when the volume of the steam has become very great, to be effectively utilised, to a degree which is impracticable in the other type, because of the enormous size which the cylinder would have to assume and the waste of work that would be caused by piston friction, if the steam were expanded down to a very low pressure by the piston method. The turbine method escapes these difficulties; mainly for that reason it has become the most efficient way of converting heat into work, on a large scale, through the agency of steam. It has further advantages in compactness, in simplicity of working, and in the facility with which it can be adapted to take steam of exceptionally high mitial pressure and high superheat.

### HISTORICAL.

In any historical sketch of the steam-engine, stress must be laid on the work of James Watt. But a process of evolution had been going on before his time which prepared a crude and primitive device for the immense improvements it received at his hands. The labours of Watt stand in natural sequence to those of Newcomen, and Newcomen's to those of Papin and Savery, Savery's engine, in its turn, was the reduction to practical form of an ancient scientific toy. Along another line of development, the modern steam turbune, which we owe to the gentus of Charles Parsons, can be traced back to an early prototype.

In the Prounation of Hero of Alexandria (a. 130 nc.) there is described the acolipile, which may be called a primitive steam reaction turbine. It consists of a hollow globe pivoted so that it can turn on a pair of central truminos, and supplied with steam through one of them, which is hollow. The steam escapes from the globe to the outside air through two bent pipes facing tan-

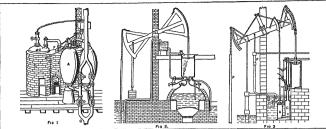

FIG 1 SAVERY'S STEAM ENGINE (1698). FIG. 2. NEWCOMEN AND CAWLEY STEAM ENGINE (1705). FIG 3 THE WATT PUMPING ENGINE

gentially in opposite directions at the ends of a diameter perpendicular to the axis. The globe revolves by reaction from the escaping steam. Here's volume also mentions (Greenwood's translation of Hero's Pnessmatics) another device which may be described as the prototype of the pressure engine. A hollow altar containing air is heated by kinding a fire on it, the air explanation and by its pressure directs some of the water in a vessel below into a hanging bucket, which then descends, opening the doors of a shrine. When the fire is extinguished the air contracts, the bucket emtiles, and the doors close

In a treatise on pneumatics (160r) by Giovanni Battista della Porta there is shown a somewhat similar apparatus, but with stam for working substance. Its pressure forces up water from a separate vessel. He also points out that the condensation of the steam may be used to produce a vacuum and thereby suck up water from a lower vessel. His suggestions go far to anticipate the engine which, a century later, in the hands of Savery, became the first commercially successful steam engine

Meanwhile Edward Somerset, second Marquis of Worcester, described in lie Century of Justicians (25 Section 18 of S

Savery, 1698 .- The earliest steam-engine to take a practical form and find employment in industry was that of Thomas Savery, who, in 1698, obtained a patent for a water-raising engine, shown in fig. 1. Steam is admitted to one of the oval vessels A, displacing water, which it drives up through the check-valve B. When the vessel A is emptied of water the supply of steam is stopped, and the steam already there is condensed by allowing a jet of cold water from a cistern above to stream over the outer surface of the vessel. This produces a vacuum and causes water to be sucked up through the pipe C and the valve D. Meanwhile steam has been displacing water from the other vessel, and is ready to be condensed there. The valves B and D open only upwards. The supplementary boiler and furnace E are for feeding water to the main boiler; E is filled while cold and a fire is lighted under it; it then forces a supply of feeding-water into the main boiler F. The gauge cocks G, G are an interesting detail. Another form of Savery's engine had only one displacement-chamber and worked intermittently. In the use of artificial means to condense the steam, and in the application of the vacuum so formed to raise water by suction from a level lower than that of the engine, as well as in practical features, Savery's engine marked an inventive advance. It found considerable employment in pumping mines and in raising water to supply houses and towns, and even to drive water-wheels. A serious difficulty which prevented its general use in mines was the fact that the height through which it would lift water was limited by the pressure the

boiler and vessels could bear. Pressures as high as 8 or 10 atmosphers were employed—and that, too, whthout a safety-valve —but Savery found it no easy matter to deal with high-pressure steam Apart from this drawback, the waste of fuel was enormous, from the condensation of steam which took place on the surface of the water and on the soles of the displacement-chamber at each operation, the consumption of coal was, in proportion to the work done, some twenty times greater than in a modern engine

Before Savery's engine was displaced by its successor, Newcomen's, it was improved by J. T. Desaguilers who applied the the safety valve (invented by Papin), and substituted condensation by a jet of cold water within the vessel for the surface ondensation used by Savery. To Savery is ascribed the first use of the term 'Borse-cowerd' as a measure of performance

In 1690 Denis Papin suggested that the condensation of steam should be employed to make a vacuum under a piston previously raised by the expansion of the steam. Papin's was the earliest cylinder and piston steam engine, and his plan of using steam was that which afterwards took practical shape in the atmospheric engine of Newcomen But his scheme was made unworkable by the fact that he proposed to use but one vessel as both boiler and cylinder A small quantity of water was placed at the bottom of a cylinder and heat was applied When the piston had risen the fire was removed, the steam was allowed to cool, and the piston did work in its down-stroke under the pressure of the atmosphere After hearing of Savery's engine in 1705 Papin turned his attention to improving it, and devised a modified form, with a floating diaphragm or piston on the top of the water to keep the water and steam from direct contact with one another Papin's engine may be described as a non-condensing single-acting steam pump. with steam cylinder and pump cylinder in one Newcomen's Atmospheric Engine, 1705.—While Papin was

thus going back from his first notion of a piston engine to Saveery's cruder type, a new inventor had appeared who made the piston engine a practical success by separating the boiler from the cylinder and by using (as Savery had doop artificial means to condense the steam. This was Thomas Newcomen, who in 1705, with his assistant, John Cawley, gave the steam engine the form shown in fig. 2. Steam admitted from the boiler to the cylinder by the opening of a valve allowed the piston to be raised by a heavy counterpolse on the other side of the beam. Then the steam valve was shut and a Jet of cold water entred the cylinder and condensed the steam. The piston was consequently forced to the steam valve was shut and a Jet of cold water entred the cylinder and condensed the steam. The piston was consequently forced from the cylinder through an escape valve. The piston was kept tight by a layer of water on its upper surface. Condensation was at first effected by cooling the outside of the cylinder, but an accidental leakage of the packing water past the piston showed the advantage of condensing by a jet of injection water, and this plan took the place of surface condensation. The engine used steam whose pressure was little if at all greater than that of the

atmosphere

About 1711 Newcomen's engine began to be introduced for pumping mines It is doubtful whether the action was originally automatic, or depended on the periodical turning of taps by an attendant The common story is that in 1713 a boy named Humphrey Potter, whose duty it was to open and shut the valves of an engine he attended, made the engine self-acting by causing the beam itself to open and close the valves by suitable cords and catches This device was simplified in 1718 by Henry Beighton, who suspended from the beam a rod called the plug-tree, which worked the valves by means of tappets By 1725 the engine was in common use in collieries, and it held its place without material change for about three-quarters of a century in all Near the close of its career Newcomen's engine was much improved in its mechanical details by John Smeaton, who built many large engines of this type about the year 1770, just after the great step which was to make Newcomen's engine obsolete had been taken by James Watt.

Compared with Savery's engine. Newcomen's had (as a numping engine) the great advantage that the mtensity of pressure in the pumps was not in any way limited by the pressure of the steam It shared with Savery's, in a scarcely less degree, the defect already pointed out, that steam was wasted by the alternate heating and cooling of the vessel into which it was led. Though obviously capable of more extended uses, it was in fact almost exclusively employed to raise water-in some instances for the purpose of turning water-wheels to drive other machinery. Even contemporary writers complain of its great consumption of fuel.

James Watt, 1763, 1769, 1781, etc.—In 1763 James Watt, an instrument maker in Glasgow, while engaged by the University in repairing a model of Newcomen's engine, was struck with the waste of steam to which the alternate chilling and heating of the cylinder gave rise. He saw that the remedy, in his own words, would lie in keeping the cylinder as hot as the steam that entered it. With this view he added to the engine a new organ-namely the "separate condenser"—an empty vessel separate from the cylinder, into which the steam should be allowed to escape from the cylinder, to be condensed there by the application of cold water either outside or as a jet. To preserve the vacuum in his condenser he added a pump called the air pump, whose function was to extract from it the condensed steam and water of condensation, as well as any air which might come in by leakage or by solution in the steam or the injection water. Then, as the cylinder was no longer used as a condenser, he was able to keep it hot by clothing it with non-conducting bodies, and in particular by the use of what is called a steam-jacket-a layer of hot steam between the cylinder and an external casing. Further and still with the same object, he covered in the top of the cylinder, taking the piston-rod out through a steam-tight gland or stuffing-box, and allowed steam instead of air to press upon the piston's upper surface. After much experiment Watt patented his improvements in 1769; they are described in a specification from which the following extracts are taken:-

"My method of lessening the consumption of steam, and conse-"My method of lessessing the consumption of steam, and consequently risk, in irre-suppase, consists of the following principles—quently risk, in irre-suppase, consists of the following principles—to work the engine, which is called the cylinder in common firenges, and which I call the steam vessel, must, during the whole line the engine as at work, be kept as hot as the steam that enter the steam that the st

time. "Secondly, In engines that are to be worked wholly or partially by condensation of steam, the steam is to be condensated in vessels distinct from the steam-tested or cylinders, although occationally communicating with them; these sense that the condensate of the steam-tested or the steam of the st

stam to press on the pistons, or whatever may be used instead of them, in the same manner in which the pressure of the atmosphere as now employed in common fire-engines I nesses where cold water cannot be had in plenty, the engues may be wrought by this force of steam only, by dividiarigm the steam into the air after it has done

The "common fire-engine" alluded to was the steam engine of Newcomen Highly important as Watt's first inventions were, they resulted for a time in the production of nothing more than a greatly improved engine of the Newcomen type, much less wasteful of fuel, able to make faster strokes, but still only suitable for pumping, still single-acting, with steam admitted during the whole stroke, the piston, as before, pulling the beam by a chain working on a circular arc. The condenser was generally worked by intection, but Watt has left a model of a surface condenser made up of small tubes, in every essential respect like the condensers now used

Fig. 3 is an example of the Watt pumping engine of this period. It should be noticed that, although the top of the cylinder is closed, and steam has access to the upper side of the piston, this is done only to keep the cylinder and piston warm. The engine is still single-acting, the steam on the upper side merely plays the part which was played in Newcomen's engine by the atmosphere; and it is the lower end of the cylinder alone that is ever put in communication with the condenser. There are three valves, the "steam" valve a, the "equilibrium" valve b, and the "exhaust" valve c. At the beginning of the down-stroke c is opened to produce a vacuum below the piston and a is opened to admit steam above it. At the end of the down-stroke a and c are shut and b is opened. This puts the two sides in equilibrium and allows the piston to be pulled up by the pump-rod P, which is heavy enough to serve as a counterpoise C is the condenser, and A is the airpump, which discharges into the hot well H, whence the supply of the feed-pump F is drawn.

In a second patent (1781) Watt describes the "sun-and-planet" wheels and other methods of making the engine give continuous revolving motion to a shaft provided with a flywheel. The crank and connecting-rod-already a familiar mechanical device from its use on the treadle of a lathe-would have been the natural means of doing this, but its application to the steam engine in a particular manner had been made the subject of a patent by James Pickard, and Watt, rather than make terms with Pickard whom he regarded as a plaguarist of his own ideas, made use of his sun-and-planet motion until the patent on the crank expired. The reciprocating motion of earlier forms had served only for pumping; by making the steam engine drive a revolving shaft Watt opened up for it many other channels of usefulness. The engine was still single-acting; the connecting-rod was attached to the far end of the beam, and that carried a counterpoise which served to raise the piston when steam was admitted below it.

In 1782 Watt patented two further improvements of the first importance, both of which he had invented some years before. One was the use of double action, that is to say, the application of steam and vacuum to each side of the piston alternately. The other (invented as early as 1769) was the use of steam expansively, in other words the plan, essential to economy of fuel, of stopping the admission of steam when the piston had made only a part of its stroke, and allowing the rest of the stroke to be performed by the expansion of the steam already in the cylinder 'To let the piston push as well as pull the end of the beam Watt devised his so-called parallel motion, an arrangement of links connecting the piston-rod head with the beam in such a way as to guide the rod to move in a very nearly straight line. He further added a throttle valve, for regulating the rate of admission of steam, and a centrifugal governor, in the form of a double conical pendulum, which controlled the speed by a throttle-valve.

Among other important devices associated with Watt was the "indicator," by which diagrams showing the relation of the steam pressure in the cylinder to the movement of the piston are automatically drawn: its invention seems to have been mainly due to his assistant Tohn Southern.

In partnership with Matthew Boulton, Watt carried on in Birmingham the manufacture and sale of his engines with great success, and held the field against all rivals in spite of severe assaults on the validity of his patents. Notwithstanding his knowledge of with hot and cooler steam. The introduction of compound exthe advantage to be gained by using steam expansively, he continued to employ only low pressures-seldom more than 7 lb per square inch over that of the atmosphere. His boilers were fed, as Newcomen's had been, through an open pipe which rose high enough to let the column of water in it balance the pressure of the steam. He gave a definite numerical significance to the term "horse-power," defining it as the rate at which work is done when 33,000 lb are raised one foot in one minute

In the fourth claim of Watt's first patent, quoted above, the second sentence describes a non-condensing engine, which would have required steam of a higher pressure. This, however, was a line of invention which Watt did not follow up, perhaps because so early as 1725 a non-condensing engine had been described by

Jacob Leupold in his Theatrum machinarum.

It was not till much later that the thermodynamic principles underlying the action of the steam engine came to be understood Engineers were consequently slow to appreciate the fact that to obtain economy of fuel it was advantageous to employ a high initial pressure, in combination with much expansion in the cylin-

der and with the separate condenser of Watt.

Trevithick, Bull and Evans .- The introduction of the noncondensing and, at that time, relatively high-pressure engine was effected in England by Richard Trevithick and in America by Oliver Evans about 1800. Both Evans and Trevithick applied their engines to propel carriages on roads, and both used for boiler a cylindrical vessel with a cylindrical flue inside containing the fire -the construction now known as the Cornish boiler In association with Edward Bull, Trevithick had previously made direct acting pumping-engines, with an inverted cylinder set over and in line with the pump-rod, thus dispensing with the beam that had been a feature in all earlier forms But in these "Bull" engines, as they were called, the steam was condensed by a jet of cold water in the exhaust-pipe, and Boulton and Watt successfully opposed them as infringing Watt's patent. To Trevithick belongs the honour of being the first to use a steam carriage on a railway, in 1804 he built a locomotive in the modern sense, to run on what had formerly been a horse-tramway, in Wales In this connection it may be added that as early as 1769 a steam carriage for roads had been built in France by Nicolas Joseph Cugnot, who used a pair of single-acting high-pressure cylinders to turn a driving axle step by step by means of pawls and ratchet-wheels. To the initiative of Evans may be ascribed the early general use of highpressure steam in the United States, a feature which for many years distinguished American from English practice. (See Loco-

Compound Engine and Cornish Engine.—Among contemporaries of Watt the name of Jonathan Hornblower deserves special mention. In 1781 he constructed and patented what would now be called a compound engine, with two cylinders of different sizes. Steam was first admitted into the smaller cylinder, and then passed over into the larger, doing work against a piston in each. In Hornblower's engine the two cylinders were placed side by side, and both pistons worked on the same end of a beam overhead. This was an instance of the use of steam expansively, and as such was earlier than the patent, though not earlier than the invention, of expansive working by Watt. Hornblower was crushed by the Birmingham firm for infringing their patent in the use of a separate condenser and air-nump. The compound engine was revived in 1804 by Arthur Woolf, with whose name it is often associated. Using steam of fairly high pressure, and cutting off the supply before the end of the stroke in the small cylinder, Woolf expanded the steam to several times its original volume. Mechanically the two-cylinder compound engine has some advantage over a onecylinder engine with the same amount of expansion, in exerting a more uniform driving effort. But another and more important merit of the system lies in the fact that by dividing the whole range of expansion into two parts the cylinders in which these are separately performed are subject to a reduced range of fluctuation in their temperature. This helps to limit a source of waste which is present in all piston engines, namely the waste which results from the heating and cooling of the metal by its alternate contact

pansion forms the most outstanding improvement which steam engines of the piston and cylinder type have undergone since the time of Watt

Woolf introduced the compound engine somewhat widely about 1814 as a pumping engine in the mines of Cornwall But here it met a strong competitor in the high-pressure single-cylinder engine of Trevithick, which had the advantage of greater simplicity in construction. Woolf's engine fell into comparative disuse, and the single-cylinder type took a form which, under the name of the Cornish pumping-engine, was for many years famous for its great economy of fuel In this engine the cylinder was set under one end of a beam, from the other end of which hung a heavy rod which operated a pump at the foot of the shaft. Steam was admitted above the piston for a short portion of the stroke, thereby raising the pump-rod, and was allowed to expand for the remainder Then an equilibrium valve, connecting the space above and below the piston, as in fig 3, was opened, and the pump-rod descended, doing work in the pump and raising the engine piston The large mass which had to be started and stopped at each stroke served by its inertia to counterbalance the unequal pressure of the steam, for the ascending rods stored up energy of motion in the early part of the stroke, when the steam pressure was greatest, and gave out energy in the later part, when the pressure was much lowered by expansion The frequency of the stroke was controlled by a device called a cataract, consisting of a small plunger pump, in which the plunger, raised at each stroke by the engine, was allowed to descend more or less slowly by the escape of fluid below it through an adjustable orifice, and in its descent liberated catches which held the steam and exhaust valves from opening A similar device controlled the equalibrium valve, and could be set to give a pause at the end of the piston's down-stroke, so that the pump-cylinder might have time to become filled.

The final revival of the compound engine did not occur until about the middle of the 19th century, and then several agencies combined to effect it. In 1845 John M'Naught introduced a plan of improving beam engines of the original Watt type, by adding a high-pressure cylinder whose piston acted on the beam between the centre and the fly-wheel end Steam of higher pressure than had formerly been used, after doing work in the new cylinder. passed into the old or low-pressure cylinder, where it was further expanded. Many engines whose power was proving insufficient for the extended machinery they had to drive were "M'Naughted" in this way, and after conversion were found not only to yield more power but to show a marked economy of fuel. pound form was selected by William Pole for the pumping engines of Lambeth and other waterworks about 1850; in 1854 John Elder began to use it in marine engines; in 1857 E. A. Cowper added a steam-jacketed intermediate reservoir for steam between the high- and low-pressure cylinders, which made it unnecessary for the stroke of the low-pressure piston to be just beginning when that of the other piston was just ending. As facilities increased for the use of high-pressure steam, compound expansion came into more general use, its advantage becoming more conspicuous with every increase in boiler pressure. In marine practice, where economy of fuel was from the first an obviously important factor in design, the principle of compound expansion was extended by the introduction of triple and even quadruple expansion engines

Application to Locomotives and Steamboats,-The adaptation of the steam engine to railways, begun by Trevithick, became a success in the hands of George Stephenson, whose engine, the "Rocket," when tried along with others in 1829, distanced its competitors The principal features of the "Rocket" were an improved steam-blast for urging the combustion of coal and a boiler (suggested by Henry Booth) in which a large heating surface was given by the use of many small tubes through which the hot gases passed. Further, the cylinders, instead of being vertical as in earlier locomotives, were set at a slope, which was afterwards altered to a position more nearly horizontal. To these features there was added later the "link motion," a contrivance which enabled the engine to be easily reversed, and the amount of expansion to be readily varied. In the hands of George Stephenson

and his son Robert the locomotive took a form which in the main is retained by the far heavier locomotives (q.v.) now in use.

The first practical steamboat was the tig "Charlotte Dundae," built by Wilhiam Symington, and tred in the Forth and Clyele canal in 1802. A Watt double-acting condensing engine, placed a shaft at the stern, which carried a revolving paddic-wheel The trail was successful, but steam towing was abandoned for fear of injuring the banks of the canal Ten years later Henry Bell built be "Comet," with side paddic-wheels, which ran as a passenger steamer on the Clyde, but an earlier inventor to follow up Symington's success was the American, Robert Pullon, who, after unsuccessful experiments on the Seine, fitted a steamer on the Hudson in 1807 with engines made to his designs by Boulton and Widon in 1807 with engines made to his designs by Boulton and Widon in 1807 with engines made to his designs by Boulton and Widon success

Rise in Steam Pressure and in Piston Speed,-With improvements in the details of design and construction it gradually became practicable to use higher steam pressures and higher piston speeds, and consequently to obtain not only greater efficiency, but also a greater amount of power from engines of given bulk The triple expansion engine, introduced by A. C. Kirk in 1874, did not come into general use until after 1881. It became the normal type of marine engine, with pressures ranging, as a rule, from 150 to 200 lb per sq inch, piston speeds generally of 500 or 600 ft per minute, but sometimes as high as 900 or 1,000, and coal consumption of about 14 lb per hour per indicated horsepower It continues to be very largely used in steamships which are not driven by turbines In some instances quadruple expansion has been preferred, with somewhat higher pressures, but when the pressure is much raised the tendency is to abandon the piston type in favour of the steam turbine. This is true both in marme and in land practice. The gigantic concentration of steam power that is found in a great steamship or in a power station has been made practicable by the turbine. The selection of Parsons turbines in 1907 as the motive engines of the Cunarders "Lusi-tania" and "Mauretania" constituted a new departure in steam engineering. It was then a novelty to develop some 70,000 horsepower in the engine room of a single ship. Many of the turbines in power stations now exceed this figure

introduction of the Steam Turbine.—The invention of the steam turbine has revolutionized marme engine practice, in respect especially of the largest and fastest vessels. For the generation of electricity the turbine has a notable advantage in directly developing the high speed of rotation which a dynamo requires, and, when designed on a large scale, its efficiency is unnvailed by steam engines of other kinds To Sir Charles Parsons we owe not only the main idea of the modern steam turbine, but also the invention of many mechanical features and details essential to its

practical success and general adaptation In the steam turbine, as we have seen, pressure, instead of being exerted on a piston, is employed in the first instance to set the fluid itself in motion. There is a conversion of pressure-energy into velocity-energy as a preliminary step towards obtaining the effective work of the machine. If this were done in a single step it would involve immensely high velocities in the steam jet and in the vanes on which the jet acts Attempts to design a steam turbine were made by numerous inventors, but fell short of practical success mainly because of the difficulty of arranging for high enough velocity in the working parts to utilize a reasonably large fraction of the kinetic energy of the steam. There was a further difficulty in getting the energy of the steam into a suitable kinetic form, namely, to get the stream of issuing particles to take a single direction, without undue dispersion, when steam was allowed to expand through an orifice from a chamber at high

pressure into a space where the pressure was greatly less.
In 1869 Dr. Gustaf de Laval introduced a form of steam turhin in which both of these difficulties were, to a considerable degree, overcome, partly by the special form of the nozzle used to
produce the isteam jet and partly by features of design which allowed an exceptionally high speed to be reached in the wheel carrying the vanes against which the steam impinged.

Parsons attacked the problem at an earlier date and in a different way, by his invention of the "compound" turbine He divided the whole expansion of the steam into a great number of successive and separate steps and thereby limited the velocity acquired at each step to such an extent as to make it comparatively easy to extract the greater part of the kinetic energy as work done upon the moving blades, without making the velocity of these blades inconveniently high Moreover, in Parsons's compound turbine the range of pressure through which the steam expands in each separate step is too small to cause any difficulty in the formation of the jets. The guide blades, which form the jets, are distributed round the whole circumference of the revolving wheel and all the revolving blades are consequently in action at once The steam streams from end to end of the turbine through an annular space between a revolving drum and the casing which surrounds it Parallel rings of fixed guide blades project inwards from the casing at suitable distances, and between these are rings of moving blades which project outwards from the drum and revolve with it At each step in the expansion the steam streams through a ring of fixed guide blades, and the streams so formed impinge on the next ring of moving blades, and so on. The construction, which is of great simplicity, is described, along with others, in the article TURBINE. STEAM. It lends itself well to the generation of power on a large scale, especially where a fairly high speed of rotation is wanted Parsons introduced his compound steam turbine in 1884. For

355

some years it was made in small sizes only, and the steam was discharged to the atmosphere without condensation. So long, however, as this was done the steam turbine was sacrificing one of its most important advantages, namely, its exceptional capacity for utilizing the energy of low-pressure steam down to the lowest vacuum obtainable in a condenser. In 1891 it was first fitted with a condenser, and it then began to be used in electric supply stations The first application to marine propulsion was in the "Tur-binia," in 1897 The success of this little experimental vessel of 100 tons, which, with its horse-power of 2,100, made what was then a record in speed for any ship, was soon followed by the application of the turbine to war-ships and other steamers. In merchant vessels its use was at first limited to those of the highest speed, for the turbine shaft was directly coupled to the shaft of the screw propeller; but in 1910 Parsons introduced a mechanical reducing gear between the two, which allowed the turbine shaft to run much faster than the propeller shaft, to the great advantage in efficiency of both turbme and propeller. Later he followed this up by a "double-reduction" gearing which admitted of a still greater difference in speed of rotation between the propeller and the turbine. In most ships the single reduction system is sufficient for the purpose: its introduction greatly extended the range within which the turbine could be advantageously substituted for the three-cylinder or four-cylinder compound engine of the piston type in ocean-going steamships.

Enough has been said to show that the invention of the steam turbine is by far the most important step in steam engineering since the time of Watt. It solved the problem of using steam efficiently in an engine without reciprocating parts.

Early Theory .- In the early development of the steam engine inventors had little in the way of theory to guide them. Watt had the advantage of a knowledge of Joseph Black's doctrine of latent heat; but there was no philosophy of the relation of work to heat until long after the inventions of Watt were complete. The theory of the steam engine as a heat engine may be said to date from 1824, when N. L Sadi Carnot published his Réflexions sur la buissance motrice du feu, a remarkable essay in which he showed that heat does work only by being let down from a higher to a lower temperature. But Carnot was not then aware that any of the heat disappears in the process, and it was not until the doctrine of the conservation of energy was established in 1843 by the experiments of James Prescott Joule that the theory of heat engines began a vigorous growth. From 1849 onwards the science of thermodynamics was developed with extraordinary rapidity by Rudolf Clausius, W. J. Macquorn Rankine and William Thomson (Lord Kelvin) and was applied, especially by Rankine, to practical problems in the use of steam Rankine's Manual of the Steam Engine, published in 1859, was the first attempt at a systematic treatment of steam-engine theory It involved the simplifying assumption that the cylinder and piston might be treated as behaving to the steam like non-conducting bodies, in other words, that the transfer of heat between the steam and the metal might generally be disregarded. One effect of this was to treat the volume of steam consumed per stroke as corresponding to the volume of the cylinder up to the point of cut-off When steam enters the engine cylinder it finds the metal chilled by the previous exhaust, and a portion of it is at once condensed. This has the effect of increasing, often very largely, the volume of boiler steam required per stroke. As expansion goes on, the water that was condensed during admission begins to be re-evaporated, and this action is often prolonged into the exhaust. It is now recognized that exchanges of heat between the steam and its metal envelope cannot be ignored They cause the actual performance to fall short, in some cases very much short, of the ideal limit They may be reduced by suitable design

# ACTION OF RECIPROCATING ENGINES

Most, though not all, reciprocating engines are double-acting: that is to say, steam from the boiler is alternately admitted to each side of the piston. In each double stroke, or revolution, there are four events for each end of the cylinder -(1) Admission, which begins by the opening of a steam-valve when the piston is at or very near the limit of its travel; (2) Cut-off, at which the steam-valve is closed and admission ceases. This may take place early in the stroke. The steam which is enclosed behind the piston then expands, with falling pressure, while the stroke continues, until (3) Release occurs; that is to say, an exhaustvalve opens, allowing the steam to escape from the cylinder Its discharge generally continues for a large part of the back-stroke, until event (4), at which the exhaust-valve closes, and Compression begins. from there to the end of the back-stroke, the steam remaining in the cylinder is compressed into the clearance space behind the piston This compression of the residue of steam, which is called cushioning, assists smoothness of working as the piston passes what is called the dead-point, at the limit of its stroke; and the cushioning effect is often augmented by giving the steam-valve what is called "lead,"—that is, causing it to open a little before the piston reaches the dead point. Distribution of the Steam: Indicator Diagram.—Together,

these various events of the stroke constitute what is termed the distribution of the steam They are conveniently exhibited by drawing an indicator diagram of the action, such as that illustrated in fig 4 There, on a base PQ which represents the stroke, lines are drawn to show the continuous changes of pressure that go on within the cylinder during the whole action. Starting from the beginning of the stroke at a, for one side of the piston, steam is admitted up to the point b which shows the cut-off. At (or near) the end of the forward stroke, at c, the steam is allowed to escape. Compression, in the return stroke, begins at d. From b to c the steam confined in the cylinder is expanding, with falling pressure, doing work on the piston. The whole work done in the revolution.

namely the integral of the force acting on the piston and the distance through which it moves, is represented by the enclosed area of the indicator diagram, abed

The diagram is idealised in the sense that the events are shown as if they happened suddenly, Fig 4.—INDICATOR DIAGRAM giving sharply defined changes snowing distribution of Steam

from admission to expansion and so on. In any real engine the events are necessarily gradual, for no valve-whatever its type -can close or open quite instantaneously. A real indicator diagram accordingly has a smoother outline with rounded corners to mark the places of cut-off, release, compression and admission. In practice release always occurs before the piston has quite completed its stroke.

The distance PO which represents the stroke may (by the use of an appropriate scale) be interpreted as a volume, namely the volume swept through by the piston, and a point O behind P may be so taken that OP represents, on the same scale, the volume of the clearance The distance measured horizontally from the line OY to any point of the curve represents the whole volume of steam behind the piston at that point, and the curve between admission and release exhibits the relation of the pressure to the

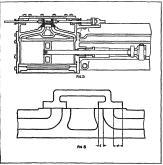

Fig 5 .- CROSS SECTION DIAGRAM OF A SLIDE-VALVE SHOWING EXHAUST AND INLET PORTS BELOW IT, AND CYLINDER AND PISTON FIG 6 .- CROSS SECTION OF SLIDE-VALVE IN MIDDLE POSITION, (1) INTERNAL LAP, (E) EXTERNAL LAP

total volume of the steam enclosed behind the piston throughout its process of expansion

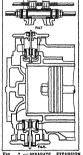

Actual indicator diagrams may be automatically drawn by attaching to the cylinder of the engine a device in which a pencil is made to rise or fall proportionally to the variations of steam pressure, while a paper, on which it inscribes a record, moves back and forth horizontally through distances proportional to the movement of the engine piston Many forms of indicator have been designed to give, in some such way, a diagram in which the coordinates represent respectively the displacement of the piston and the pressure of the steam against it. From such diagrams it is easy to infer the mean effective pressure throughout the stroke. and also to observe how the valves are working By connecting the instrument successively to each of the two ends of the cylinder, in a double-acting engine, a complete record is obtained for the two strokes which make up a revolution The "indicated horse-power" is determined by the formula

I.H.P. = 
$$\frac{nL(p_1A_1 + p_2A_2)}{33,000}$$

where A1 and A2 are the areas of the two sides of the piston, in square inches; p1 and p2 are the mean effective pressures on the two sides, in lb. per sq inch, as determined from the diagrams, n is the number of revolutions per minute, and L is the stroke in feet. In trials of a steam engine such diagrams are taken during a considerable period. The amount and condition of the steam passing through the engine is observed, by measuring either the quantity of water discharged from the condenser (if of the surface type), or the quantity of feed-water required to be supplied to the boiler to keep the water level constant From these data it becomes possible to compare the power developed with the heat supplied. Measurements of the heat rejected may also be made by observing the quantity of condensing water used and its rise in temperature; and together these figures give material for drawing up a balance sheet of the disposal of thermal energy.

each end of the cylinder, may be controlled by separate valves, but very commonly a single moving piece, called a slide-valve, serves to control the events for both ends. The slide-valve was invented by William Murdock, an assistant of Watt A common form of it is illustrated in section in fig 5, which also shows the cylinder, with the piston, and the steam ports and passages leading to each end of the cylinder. The face on which the valve slides is a plane surface on one side of the cylinder with three ports or openings which extend across the greater part of the cylinder's width The central opening is the exhaust port, through which the steam escapes after doing its duty in the cylinder. The others, which are narrower, lead to the two ends. The valve itself is a box-shaped cover, sliding on the face, and contained in the valve-chest, or chamber to which steam is admitted from the hoiler. When the valve moves a sufficient distance to either side of the middle position steam is admitted to one end of the cylinder, past the outer edge Similarly steam escapes from the other end of the cylinder, through the cavity of the valve, to the exhaust port The valve takes its motion from an eccentric on the engine shaft, which is set more than goo ahead of the crank, so that the valve has already begun to uncover the port on one side when the piston is at the corresponding dead point, with the result that steam passes from the steam chest above the valve into the space behind the piston Figure 6 shows a slide-valve in its middle position, and illustrates the internal lap s and the external lap e which the valve must have to make expansive working possible. At the beginning of the stroke it has already passed its middle position by an amount at least equal to e, so that steam may enter. It contimues to move further, opening the port more widely, and then begins to return, while the piston is still advancing in the cylinder, At a particular point in its return the outer edge of the valve closes the port; this determines the instant of cut-off. The piston continues to advance, with expansion of the steam confined in the cylinder, while the valve continues to move back, until the inner

edge of the valve begins to uncover the port, allowing steam from the cylinder to escape to the exhaust channel. This point, which depends on the internal lap s, determines the instant of release. The port then opens more widely to exhaust, and remains open during most of the back stroke of the piston, until the valve, again moving in the original direction, brings its inner edge again over the port and compression begins. Similar events for the other end of the cylinder are determined by the other side of the valve The positions of the piston when the several events occur depend on the amounts of the laps e and i, and of the "angular advance" which is the excess over 90° in the angle by which the eccentric stands ahead of the crank. If there were no laps and no angular advance steam would be admitted during the whole forward stroke and exhausted during VALVE

the whole backward stroke. By Fig. 8 .- cross section of one giving the valve laps and angular END OF A CYLINDER SHOWING DROP VALVES advance expansive working be-

comes possible. But the slide-valve is not well adapted to effect a cut-off early in the stroke, and when much expansion is desired, a device called a separate expansion valve is added, or valves of a different type are used to control the distribution of the steam.

Separate Expansion Valves.-Fig. 7 shows Meyer's expansion valve, which consists of two blocks sliding on the back of a slide-valve. It is caused to reciprocate by an eccentric, generally

The Slide-valve.—The admission and exhaust of steam, for set directly opposite the crank, so that it moves to the left while the piston moves to the right, and vice verse. The admission of steam ceases when the relative displacement of the expansion blocks over the slide-valve amounts to the distance I, and this can be arranged to happen early in the piston's stroke without affecting the release or the compression

In this example the rod which carries the two blocks is fitted with right- and left-handed screws, so that by turning the rod the distance between the blocks may be adjusted, and the distance I consequently altered This allows the valve to be set to give an earlier or later cut-off when I is increased by bringing the blocks nearer together, the cut-off comes later in the stroke The adjustment may be made while the engine is running. Another way to change the cut-off with a valve of the Meyer type is to alter its travel Increasing the travel of the expansion valve, while I remains constant, makes the cut-off come later

In many engines the events are controlled by using, at each end of the cylinder, separate valves for admission and exhaust (fig 8). Sometimes these are drop valves which are "doublebeat" in the sense that the valve when it drops into its seat closes simultaneously two passages. These are so arranged that the steam pressure tending to close or open the valve remains balanced, and no large force has to be exerted. Such valves are often worked by cams and levers from a lay shaft alongside the cylinder, driven from the main shaft so as to turn in unison. In many examples the valves giving admission are caused to close by a tripping device, that is to say they spring suddenly into the closed position, at the instant when cut-off is desired, through the action of a trigger which brings a closing spring into play; and the tripping device is connected with the governor of the engine in such a manner that the cut-off comes earlier or later when the speed exceeds or falls short of the normal. In this way the engine automatically adjusts the amount of power it develops to suit changes in the demand made upon it by the mechanism which it drives,

Balanced Valves .- Fig. 5 shows a slide-valve form usual in locomotives and small engines but in large sizes the objection is that the unbalanced pressure of steam on the back of the valve would cause much friction and wear in the movement of the valve over the working face on which it slides. In large engines, such as those of steamships, it is usual to relieve the pressure of the valve on the working face by fitting the back of the valve with what is called a relief frame, extending between the valve and the steam-chest cover, the effect of which is to prevent the steam of the steam-chest from having access to the whole back surface of the valve. Another device, often resorted to, is to substitute for the flat form of slide-valve a piston form in which the effective sliding portions of the valve extend all round the surface of a cylinder and slide over cylindrical fixtures in the valve chest, round which the steam-ports extend

Reversing Gears,-The slide-valve is a particularly convenient means of controlling the admission of steam when, as in locomotives or marine engines, etc., the engine's direction of motion has frequently to be reversed. It is only necessary to provide means by which the valve may be actuated by either of two eccentrics, one set at the angle suitable for forward running and the other set at the angle suitable for backward running

In Stephenson's link motion which is an early and familiar device for this purpose, the engine shaft carries two eccentrics. one of which is set ahead of the crank at a suitable angle for one direction of running, and the other at a suitable angle for the other direction. Their rods are connected to the ends of a link which gives its name to the contrivance. The link is a slotted bar curved to a circular arc, and capable of being moved up or down, being suspended from a rod which can be raised or lowered by means of the hand lever above. The valve rod ends in a block which slides within the link. This device allows either the forward eccentric or the backward eccentric to determine the motion of the valve, and so allows the engine to be reversed But it does more, for if the link be set to an intermediate position, in which it takes its motion chiefly from one eccentric but partly from the other, the valve receives a motion virtually the same as that which it would get from a single eccentric of shorter travel and greater angular advance. The effect is to give a distribution of steam in which the cut-off is hastened and the expansion and compression are increased. Thus besides allowing of 'full forward' and "full backward gear", the link may be 'noticised up' to give a much shorter admission of steam along with more compression, a matter of practical value in the running of a locomotive, where frequent large variations in the demand for driving effort have to be met. Various other forms of inha-motion have been devised which

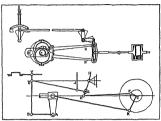

FIG. 9 — (ABOVE) STEPHENSON'S LINK MOTION. (E, L') ECCENTRICS.

share this advantage. It is also shared by a group of equivalent mechanical devices, called by the general name of "radial valve gens," in which only one eccentric is employed but the valve is caused to take a motion capable of being varied in the same way. Of these the most widely used is the Walscharer's gent, very common in bocumotives, a skeleton diagram of which is shown in fig. which is shown in the value of the same way. Of these the motion partly from it, through even  $\delta A$  and B V by B V but B V has a fulcrum at D, the position of which varies through the movement of the rod D C. That rod is supported by a suspension rod I, and its end at G can slide in a link B I rocking about a faceful cut and O. There is one eccentric, C V, set at right angles to the crank C K, and giving motion to the rocking link B V by the rod B I. The block G can be shifted from near B I to I V praising the suspension rod I. This reverses the motion, and allows also of notching up to any intermediate position.

Governing.-To keep a steam engine running at a uniform speed, notwithstanding variations in the demand for nower, hand regulation may to some extent serve, but in very many cases an automatic regulator called a governor is provided. Regulation. whether by hand or by automatic governor, may be effected in two ways: the steam may be throttled more or less on its way from the boiler to the engine, so that the pressure of admission is reduced when the speed tends to rise, and increased when the speed tends to fall; or the point of cut-off may be varied, with the result of admitting a greater or less volume of steam in each stroke. In small engines the governor often acts on a throttle valve, but at engines which aim at efficiency it is preferable to govern by altering the cut-off. In such engines, to secure in any case a proper amount of expansion, there is an early cut-off, and a small change in its position largely affects the amount of steam admitted and consequently the amount of work done.

Wait's original governor was a pair of halls revolving about a vertical spindle, as conical pendulums under the combined effect of their own weight and the "centrifugal force" due to their speed of revolution. Any increase of speed sufficient to overcome the slight friction of the attached gearing made them take up a higher position, and in so doing they partially closed a throttle valve. This went on till, at a slightly greater speed than before, equilibration was established between the supply of steam and the demandram was established between the supply of steam and the demand as strictly constant special meteors, the effect is not to maintain a strictly constant special prevent the variation, either way.

In modern governors the "centrifugal force" of the balls generally acts not simply against their own weight, but against an extra load or against the force of a spring.

In many factory and other engines the governor determines the position of cut-off by means of a trigger action of the type already mentioned: the dunision valve, which has been opened and held open by a cam turning with the engine shaft, is suddenly disconnected by the release of a trigger, at a point depending on the each height of the governor balls.

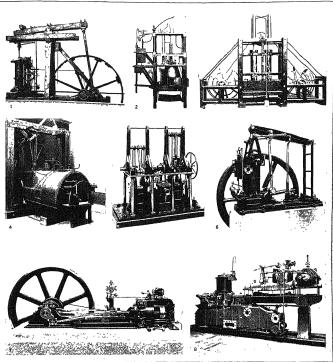

Function of the Fly Wheel.—The function of the governor is, generally, to keep the engine running at a nearly uniform rate, measured in turns per minute, the function of the flywheel is to keep the rate nearly uniform within the limits of any one revolution. For this purpose it must act as a reservoir of energy, alternately storing and restoring the excess amounts which result from periodic variations of turning moment in the operation of the piston on the crank. At the dead points the piston's rate of doing work is zero, and it rises to a maximum at an intermediate point the position of which may be much affected by an early cut-off The flywheel is drawn upon for energy during those parts of the revolution in which the work done by the piston (or pistons) on the engine shaft is less than the work done by the shaft on the mechanism which the engine drives; and it takes up the surplus during the other parts of the revolution. To effect this alternate give and take of energy the flywheel must undergo small variations of speed, the magnitude of which may be kept down to any assigned amount by giving the rim a sufficient mass and speed

Inertia of Reciprocating Parts.—The effective effort on the crank is greatly influenced, especially in high-speed engines, by the inertia of the piston, piston-rod and connecting rod. At the beginning of the stroke, when the piston is coming towards the crank-shaft, these reciprocating masses are acquiring motion, from a point near the middle to the end of the stroke they are losing motion. Hence in the early part the effort on the crank is reduced below what is due to the steam-pressure on the piston and in the later part it is increased. In a high-speed engine the forces due to acceleration become so large as seriously to affect part of the crank of the cran

Balancing of Engines.—Another aspect of the acceleration of reciprocating parts is its effect on the balance of the engine as a whole. This is specially important in locomotives and marine engines. In a locomotive he forces on the engine frame arising from the inertia of the pistons and rods tend to make the engine sway laterally; this is to some extent prevented by placing "balance masses" on the wheels But such masses, although they may be adjusted nearly to balance the horizontal forces, include unbalanced vertical forces, causing what is called hammerblow In extreme cases these vertical forces might even lift the wheels from the rails; short of that, however, they are objectionable in causing periodic variations in the pressure on the rails, which tend to set bridges into oscillation and may add substantially to the stresses for which the railsway engineer must provide.

# TYPES OF RECIPROCATING ENGINES

In classifying engines with regard to their general arrangement of parts and mode of working, account has to be taken of a considerable number of independent characteristics. We have first a general division into condensing and non-condensing engines, with a subdivision of the condensing class into those which act by surface conciensation and those which use injection. Next there is the division into compound and non-compound, with a further classification of the former as double, triple, or quadruple-expanion engines. Again, engines may be classed as single or double-acting, according as the steam acts on one or alternately on both sides of the plston. Again, a few engines—such as steam hammers and certain kinds of steam pumps—are non-rotative, that is to say, the reciprocating motion of the piston does work is might on a reciprocating piece; but generally an engine does work on a continuously revolving shaft. In most cases the crank-pin of the

## THE PROGRESS OF THE STEAM ENGINE

- One of Boulton and Watt's early (1789) rotative steam engines, among the first to utilize the double acting principle
- Model of Newcomen's steam engine (1719), the precursor of Watt's engine, and successfully used in pumpling and mine drainage. Newcomen created a vacuum within the cylinder by the condensation of steam.
- 3 Symington's original marine steam engine (1788), first used to propel a paddle-boat on Dalswinton Loch, Scotland, at a speed of about 4 m per hour
- 4 Trevithick's high-pressure, or non condensing engine (1811)
- 5 Quadruple piston-rod steeple paddle engine (1842)
- 6 Grashopper engine (1862), so-called because of the obvious resemblance of its upper and right-hand portions to that insect
- Model of single-cylinder horizontal engine (1898), with Coriliss valve gear A sectional view at the right end of cylinder reveals the piston and valve construction
- 8 Parsons' turbo-generator (1902), with upper turbine essing lifted to show roter

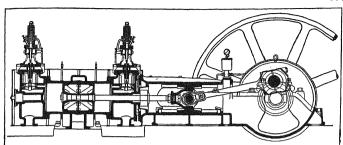

FIG 10.-UNIFLOW ENGINE IN WHICH THE PISTON ACTS AS EXHAUST VALVE AND THE ADMISSION VALVES ARE IN THE CYLINDER ENDS

revolving shaft is connected directly with the piston-rod by a connecting-rod, and the engine is then said to be direct-acting: in other cases, of which the beam engine is an historical example, a lever is interposed between the piston and the connecting-rod. The same distinction applies to non-rotative pumping engines, in some of which the piston acts directly on the pump-rod, while in others it acts through a beam. The position of the cylinder is another element of classification, giving horizontal, vertical and inclined cylinder engines In most vertical engines the cylinder is above the connecting-rod and crank In oscillating cylinder engines (a type still found in some river boats) the connecting-rod is dispensed with; the piston-rod works on the crank-pin, and the cylinder oscillates on trunnions to allow the piston-rod to follow the crank-pin round its circular path. In rotary engines there is no piston in the ordinary sense; the steam does work on a revolving piece, and the necessity is thus avoided of afterwards converting reciprocating into rotary motion.

Beam Engines—In the single-acting atmospheric engine of Newcomen the beam was a necessary feature, the use of water-packing for the piston required that the piston should move down in the working stroke, and a beam was needed to let the counter-poise pull the piston up Watt's improvements made the beam no longer necessary; and in one of the forms he designed it was discarded—namely, in the form of pumping engine known as the Bull engine, in which a vertical inverted cylinder stands over and acts directly on the pump-rod. However, the beam formed a convenient driver for pump-rods and valve-rods; and the parallel motion invented by Watt as a means of guiding the piston-rod, which could easily be applied to a beam engine, was, in the early days of engine-building, an easier thing to construct than the plane surfaces which are the natural guides of the piston-rod in a direct-acting engine. In modern practice the direct-acting type has almost wholly displaced the beam engine.

Direct-acting Engines .- Of direct-acting engines the horizontal arrangement has in general the advantage of greater accessibility, but the vertical economises floor space. In small forms the engine is generally self-contained, that is to say, a single frame or bedplate carries all the parts including the main bearings in which the crank-shaft with its flywheel turns. The frame often takes what is called a girder shape, which brings a portion of it into a favourable position for taking the thrust between the cylinder and the crank-shaft bearings and allows two surfaces to be formed on the frame to serve as guides for the cross-head. When a condenser is used with a horizontal engine it is often placed behind the cylinder, and the air-pump, which may be within the condenser, has a horizontal plunger or piston on a "tail-rod" or continuation of the main piston-rod through the back cover of the cylinder. In large horizontal engines the condenser generally is in a well below, and its pump is driven by a mechanism linked with the crosshead.

Coupled Engines.—When uniformity of driving effort or the absence of ead points is important, two independent cylinders often work on the same shaft by cranks at right angles to each other. Such engines, which are called "coupled," can start readily from any position; the ordinary locomotive engine is an example in some engines three cylinders, set to work on cranks 120 apart, co-operate in giving a still more uniform drive. Winding engines for mines and collieres, in which ease of starting, stopping an reversing is essential, are very generally made by coupling a pair of cylinders on opposits eights of the winding drum.

Compound Engines, Coupled or Tandem—Large directing engines are usually compounded either by having a highand a low-pressure cylinder side by side, with cranks at rightangles, or by putting one cylinder behind the other with a common centre line. The latter is called a tandem arrangement. In a tandem engine, since the putsons agree in phase, the steam may expand directly from the small into the large cylinder. But the connecting-pipe and steam chest form a receiver of considerable size, and it is preferable to cut off the supply of steam to the the compound tandem and conspound coupled types of engine are very usual. The high-pressure cylinder is often fitted with some form of trip-car.

The chief advantage of compounding, as was pointed out in the historical section, is that it reduces the condensation which hot steam undergoes in the cylinder through contact with metal which has been chilled by the exhaust of the previous stroke. Compound working acts beneficially by narrowing the range through which the temperature periodically by furturates in the metallic surfaces exposed to contact with the operative steam. The amount of steam that is at once condensed on admission depends on on the extent to which the surfaces with which it comes in contact has been chilled during the previous exhaust. For this reason there is less loss through initial condensation in a compound engine giving the same total ratio of expansion.

the same total ratio of expansion.

Uniflow Margine.—The periodic give and take of heat between the steam and the metallic surfaces, which is a serious source of loss in any reciprocating engine, can be reduced by having separate valves for admission and exhaust, so that the same port-surfaces and valve-surfaces are not hrought into contact with hot and comparatively cold steam. This idea is carried further in what is called the "uniflow" engine, by an ingenious arrangement which secures that the ends of the cylinder, where the steam is admitted, shall always be kept hot, the exhaust taking place at the middle of the cylinder through ports in the circumference which are uncovered by the motion of the piston.

The uniflow design is a recent but conspicuously successful departure from earlier practice. It allows high pressure steam to be expanded in a single cylinder without the drawbacks ordinarily exchange of heat between the metal and the steam to make superheating highly advantageous.

Condensation.-In land engines a jet form of condenser is common, but surface condensation is resorted to when the available water-supply is unsuited for boiler feed. When there is no large supply of condensing water a very fair vacuum can be obtained by using an evaporative condenser, consisting of a stack of pipes into which the exhaust steam is admitted and over which a small amount of cooling water is allowed to drip. This water is evaporated by the heat which the condensing steam gives up Such a condenser is placed in the open, generally on a roof where the air has free access. The amount of water it uses need not exceed the amount of steam that is condensed, and is a small fraction of the amount that would be required in a set or surface condenser

High-speed Direct-acting Engines .- Prior to the development of the steam turbine the demand for engines suitable for driving electric generators without the intervention of a belt led to the introduction of various forms of direct-acting engine adapted to run at a high speed Some of these were single-acting. steam being admitted to one side of the piston only, generally the back, with the result that the rods could be kept in a state of thrust throughout the revolution, and alternations of stress in them and at the joints thereby avoided, together with the knocking and wear of the bearing brasses which it is apt to cause. To secure, however, that the connecting-rod should always push and never pull against the crank-pin there had to be much cushioning during the out stroke on account of the fact that from about the middle of that stroke to the end the reciprocating mass was being retarded. In engines of this class designed by P. W. Willans, which were at one time much used, but are now displaced by turbines, the cushioning was provided by means of a supplementary piston which compressed air during the out stroke; the energy which the reciprocating masses had to part with in losing their motion during the second half of the out stroke was stored in this air and was restored in the succeeding down stroke. The engine was entirely enclosed in a casing the bottom of which formed an oil bath in which the cranks splashed to ensure ample lubrication. This feature is retained in many modern high-speed engines.

Pumping Engines.-In engines for pumping or for blowing air it is not essential to drive a revolving shaft, and in many forms the reciprocating motion of the steam piston is applied directly to produce the reciprocating motion of the pump-piston or plunger. Often an inverted vertical triple expansion engine is used, resembling the usual marine form, with a pump-plunger under each of the three cylinders. Most of the power is directly transmitted from the piston to the pump, but there is an auxiliary crank for each cylinder, driving a shaft with a flywheel to equalize

the effort on the pump.

A familiar example of direct-acting pump is the small donkey pump used for feeding boilers, in which the steam-piston and pump-plunger are on one and the same rod. In some of these pumps a rotative element is introduced, partly to secure steadiness of running and partly for convenience in working the valves. But many pumps of this class are entirely non-rotative, and in such cases the steam is generally admitted throughout the stroke without expansion. The valve may be actuated by tappets from the piston-rod. In some cases a tappet worked by the piston as it reaches each end of its stroke throws over an auxiliary steamvalve, which admits steam to one or other side of an auxiliary piston carrying the main slide-valve.

Pulsometer .- Hall's "pulsometer" is a peculiar pumping engine without cylinder or piston, which may be regarded as the modern representative of the engine of Savery. The sectional view, fig. 11. shows its principal parts. There are two chambers, A, A', narrowing towards the top, where the steam-pipe B enters. A ballvalve C allows steam to pass into one of the chambers and closes the other. Steam entering (say) the right-hand chamber forces water out of it past the clack-valve V into a delivery passage D, which is connected with an air-vessel. When the water level in A sinks so far that steam begins to blow through the delivery passage, the water and steam are disturbed and so brought into inti-

entailed in non-compound working. There is, however, still enough mate contact, the steam in A condenses, and a partial vacuum is formed This causes the ball-valve C to rock over and close the top of A, while water rises from the suction-pipe E to fill that chamber At the same time steam begins to enter the other chamber A', discharging water from it, and the same series of actions is repeated in each chamber alternately While the water is being driven out there is comparatively little condensation of steam. partly because the shape of the vessel does not promote the formation of eddies, and partly because there is a cushion of air between the steam and the water. Near the top of each chamber is a small air-valve opening inwards, which

METER

uum is formed. When any steam is condensed, the air mixed with it remains on the cold surface and forms a non-conducting layer. The pulsometer is, of course, far from efficient as a thermodynamic engine, but its adaptability to situations where other steam-pumps cannot easily be applied, and the simplicity of its working parts, sometimes make it practically Marine Engines.-The early steamers

allows a little air to enter each time a vac-

were fitted with paddle-wheels, and the engines used to drive them were for the

most part modified beam engines. Bell's "Comet" was driven by a species of inverted beam engine, and another form of inverted beam, known as the side-lever engine, was for long a favourite with marine engineers. An old form of direct-acting paddle-engine was the steeple engine, in which the cylinder was set vertically below the crank. Two piston-rods projected through the top of the cylinder, one on each side of the shaft and of the crank. They were united by a cross-head sliding in vertical guides, and from this a return-connecting-rod led to the crank. Most modern paddle-wheel engines are direct-acting engines of the ordinary connecting-rod type, with the cylinders fixed on an inclined bed and the guides sloping up towards the shaft.

When the screw-propeller began to take the place of paddle-

wheels in ocean steamers, the increased speed which it required was at first obtained by using spur-wheel gearing in conjunction with one of the forms of engines then usual in paddle steamers. Types of engine better suited to the screw were introduced later, and were driven fast enough to be connected directly to the screwshaft. After passing through various forms, now obsolete, the marine engine settled into one which is now universal in all screw steamships that are not driven by steam turbine

This is the inverted vertical direct-acting engine, with two or more cylinders placed side by side directly over the shaft. It has the great advantage that the shaft can readily be put at the low level necessary for screw propulsion Two, three and four cranks are employed, the arrangement with four cranks being specially suitable, as has already been pointed out, when a balance of the engine at high speeds has to be secured. In vessels of high speed and power the engines are often arranged in twin sets, on two shafts with twin screw propellers.

The marine engine is always furnished with a surface condenser, consisting of a multitude of brass tubes about 4 inch in diameter cooled by sea-water which is caused to circulate through the condenser by means of a circulating pump This pump and the air pump are often driven independently of the main engine.

It is in marine practice that the most powerful reciprocating engines are still to be found, although in the largest and fastest vessels the turbine has taken their place. Another and more recent rival is the internal combustion engine, using the Diesel cycle of action, which by 1928 had found favour in many new liners. The reciprocating engine continues, however, to be much used for sea-going vessels, especially those of the "tramp" class, most commonly in the triple expansion form. Often the third stage of the expansion is performed in two cylinders, making four in all. This avoids the use of a very large cylinder, and secures an advan-tage in the better balance which can be obtained with four cranks, Locomotive Engines.—The ordinary locomotive consists of a pair of direct-acting horizontal or nearly horizontal engines, fixed in a rigid frame under the front end of the boiler, and coupled to the same shaft by cranks at right angles, each with a single slidevalve worked by a link-motion, or by a form of radial gear The engine is non-condensing, except in a very few special cases, and the exhaust steam, delivered at the base of the funnel through a blast-pipe, serves to produce a draught of air through the furnace. In some instances a portion of the exhaust steam, amounting to about one-fifth of the whole, is diverted to heat the feed-water

On the shaft are a pair of driving-wheels, whose frictional adhesion to the rails furnishes the necessary tractive force Nearly always a greater tractive force is secured by having two or more driving-wheels on each side, connected by a coupling-rod between

pins on the outside of the wheels

It is general to have under the front of the engine a group of smaller wheels which do not form part of the driving system These are carried in a bogie, that is, a small truck upon which the front end of the boiler rests by a swivel-pin or plate which allows the bogie to turn, so as to adapt itself to curves in the line, and thus obviate the grinding of tyres and danger of detailment which would be caused by using a long rigid wheel base.

In inside-cylinder engines the cylinders are placed side by side within the frame of the engine, and their connecting-rods work on cranks in the driving shaft. In outside-cylinder engines the cylinders are spread apart far enough to lie outside the frame of the engine, and work on crank-pins on the outsides of the driving wheels Many modern locomotives combine the outside and inside arrangement, in order to get greater power, placing one or in some cases two cylinders within the frame, as well as two outside

The principle of compounding has often been applied to locomotive engines, but without much advantage. (See Locomotives.)

## THEORY OF THE STEAM ENGINE AS A HEAT ENGINE

Properties of Steam.-Steam-engine theory is an application of the principles of thermodynamics (qv) to a machine using steam as its working substance. The relevant properties of the substance have been briefly described in the article STEAM. They include the pressure, temperature, and density (or volume per unit of mass), also (per unit of mass) the entropy  $\phi$  and the total heat I. For definitions of these quantities reference should be made to that article. Numerical values will be found in Callendar's or other steam tables, over a sufficiently wide range of conditions to meet the purposes of the engineer.

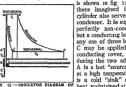

Given steam in any initial state, we have to consider what hanpens when it expands, doing work, as in the cylinder of a steam engine. It is easy to imagine steam expanding without turbulence in an ideal cylinder which is a perfect non-conductor of heat. Under these conditions no heat is being taken in, and there is no change of entropy: such expansion is said to be adiabatic. Adiabatic expansion, and adiabatic compression, although never strictly realized owing to the influence of the conducting cylinder walls, are ideal actions important in the theory of the steam engine.

During adiabatic expansion the substance is doing work at the expense of its stock of internal energy, and its temperature falls. Steam expanding adiabatically becomes partly condensed, the substance then becomes a mixture of saturated steam with water at the same temperature, and the energy or the total heat of one pound is to be found by considering what fraction is present as water and what fraction is steam. Such a mixture is often called wet steam. The degree of wetness reached at any stage of adiabatic expansion is readily calculated by taking account of the fact that the expanding mixture keeps its entropy unchanged.

From the general principles of thermodynamics it is easy to assign an upper limit to the efficiency of a steam engine, when the temperatures are known at which the working substance takes in and rejects heat. By "efficiency" is here meant the ratio of the work done to the quantity of heat supplied. Suppose, to simplify the problem, that there is no superheating, that is to say no supplementary taking in of heat after the steam has been formed at the constant temperature T, of the boiler Suppose also that the only rejection of heat is at the constant temperature Ta of the condenser. Then the principle of Carnot (see THERMODYNAMICS)

shows that under ideally favourable conditions of working the fraction of the heat supplied which is converted into work cannot exceed I-T2/T1, when the temperatures are expressed on the absolute scale

Carnot Cycle.-This result would be attained in an engine working in a strictly reversible manner, where the whole change from T, to T, occurs as a result of adiabatic expansion, and the whole change from T2 to T1 as a result of adiabatic compression The indicator diagram of an ideal engine working in this manner

CARMOT'S CYCLE

is shown in fig 12 The engine there imagined is one whose cylinder also serves as boiler and condenser. It is supposed to have perfectly non-conducting sides, but a conducting bottom to which any one of three bodies A. B. or C may be applied B is a nonconducting cover, to be applied during the two adiabatic stages A is a hot "source," maintained at a high temperature Ti, and C is a cold "sink" or receiver of heat, maintained at a low temperature T2. Imagine the cylinder

to contain one lb of water at T1 and A to be applied, while the piston begins to move towards the right The "isothermal" (constant temperature) line ab is traced out during the evaporation of the water. At b the substance is all steam. A is then removed, B is applied, and the adiabatic expansion be takes place, until the temperature of the working substance falls to T2 C is then applied and the piston is pressed back, giving an isothermal line cd during which most of the steam is condensed. At d there is a mixture, chiefly water, which is adiabatically compressed. If this point d has been properly chosen, the operation da completes the cycle, bringing the substance back to the condition a in which it 15 all water at temperature T1. The whole process is called Carnot's cycle.

The formula I-Ta/Ta which expresses the efficiency in this ideal operation shows the importance of making T1 high and T2 low. No real engine attains this limit of efficiency, for no engine completely expands the steam down to the condenser temperature in a strictly adiabatic manner. Further, no engine has an adiabatic compression stage corresponding to da; the use of a separate condenser makes that impracticable

The action in an engine cylinder may be more appropriately idealized as in fig. 13 where AB represents the admission of the steam at T1, BC its adiabatic and complete expansion to T2, and CD its rejection to the condenser Under these conditions it is easy to show that the work done, which corresponds to the area of this ideal diagram, is equal to

for each lb, of steam admitted to the engine, where I, is the total heat (per lb.) on admission, and Is is the total heat (per lb. of mixture) in the condition C, when expansion is complete. This applies whatever be the state of the steam on admission, whether superheated or not. The quantity I1-I2 is called the adiabatic

heat-drop, and measures the greatest amount of work theoretically obtainable from each lb. of steam. In practice about 70 per cent. of the adiabatic heat-drop may be realized in favourable cases. Tables of the adiabatic heat-drop, for steam in THE ACTION OF AN AVER. Various assumed initial states as to pres-

AGE PRGINE sure and temperature, expanding to various assumed condenser pressures, have been compiled, and are of great service in problems of engine design,

Rankine Cycle.—The process exhibited in fig. 13 becomes a complete cycle when, in addition, account is taken of the action by which the feed-pump restores the condensed steam to the boiler. Thus completed the process is called the Rankine cycle. Its efficiency is necessarily somewhat less than that of the Carnot cycle of fig. 12. Superheating, which is not in practice carried beyond a temperature of 4,00° C, and rarely so far, adds to the heat-drop by increasing I., But its chief effect on the efficiency of the process is mirrect. By tending to keep the steam in a drier state it greatly reduces the losses that arise through exchange of heat between the working substances and the cylinder walls in effect superheating makes the expansion more nearly adiabatic than it would otherwise be, and therefore gives a better approach to the ideal conditions of fig 12. In a turbine superheating is beneficial by reducing the friction of wet steam on the blades

Entropy-temperature Diagrams.—In exhibiting graphically the action of an engine under assumed conditions of working we may adopt various alternatives to the pressure-volume or "indicator" diagram. One interesting form takes for its two co-ordinates the temperature and the entropy. another (introduced by Mollier) takes the entropy and the total heat. Both of these diagrams are instructive in allowing the action to be traced through its several stages and in exhibiting the differences which result from varying the conditions of supply and of condensation. They show the direct influence of superheating, and the amount of wetness to be expected at any stage in the expansion. They allow, in some cases, measurement from a chart to take the place of numerical calculation; but their greatest merit is that they enable the operation of the working fluid to be visualized No account of such diagrams can, however, be attempted within the limits of this article

Modern High-efficiency Steam Plants.-In modern steam engines, especially of the turbine class where a very large range of expansion may be effectively carried out, efficiency is aimed at by using the best possible vacuum, to make T2 low, and by raising the pressure of supply to make T, high Pressures approaching 1000 lb. per square inch are not uncommon; occasionally that figure is exceeded, and even at the highest pressures some additional high-temperature heat is taken in by superheating Reheating at one or more stages during expansion is resorted to, in order to prevent the expanding steam from becoming unduly wet. Another device, which is also applied in the most economical large-scale turbine plants, is to remove a portion of the expanding steam at each of two or three stages, and apply it in heating the feedwater on its way back from the condenser to the boiler This progressive heating of the feedwater, by "bleeding" the turbine of steam which has already done more or less work, is called "cascade" feed-heating. Its effect is to make the whole cycle approach more nearly to the ideal cycle of Carnot, for the progressive feed-heating is nearly reversible and serves as a substitute, in this respect, for the adiabatic compression which makes

tute, in this respect, for the adiabatic compression which makes that cycle differ from the cycle of Rankine. Coes also Turberne: Stram; Locomotove; Marine Engineering, 100 Marine Engineering, 100 Marine Engineering, 100 Marine (1920); Marine Radiovers, 100 Marine, 100

STEAM-GAUGE is an instrument which by utilizing the elasticity of a metal indicates the pressure of steam in a bolter or other vessel. The action is explained in the article PRESSURGAUGE. The agange must be fixed above the highest water level of the boller, and stand away from it to avoid heating. A gauge is unduly hot if it cannot be touched by the hand without discomfort, and the U-tube or syphon is therefore used for connection to the boller. In norder to avoid straining the action, a gauge is generally graduated to twice the working pressure. Then the pointer stands vertically at the normal working pressure. Then the pointer stands vertically at the normal working pressure. Then the pointer stands vertically at the normal working pressure. High-pressive steam-gauges are those graduated for pressures between 20 lb. and 1,000 lb.

STEAM GENERATION. In a modern plant the course of operation can be traced broadly as follows: The water operates in a closed system and circulates in the form of steam or vapour and returns to its original state in the form of condensation. The water is first heated in feed water heaters, then goes

through the tubes in the bollers and is changed to stam, then through a superheater that adds heat to it and from there to the utilizing equipment, a turbune for example. Finally it reaches the condenser from which it is returned to the starting point. The fuel usually starts through some preparation process such as revishing. From there it is usually conveyed to bunkers that provide a continuous feed to the stokers under the boolers. It is burnt on the stoker grates in the furnaces with natural or forced draft and the gases are used as they leave the boiler in superheaters, economizers and any preheaters. From there they finally escape through the stack. The economizers, superheaters and unrepetaters are means by which some of the waste heat in the gases is reclaimed. In steam generating plants is found all oxome of this ecupipment and much other availancy equipment.

Subjects dealing with the generation of steam and with the equipment used in that process will be found in the articles: BOILERS;
STEAM; COMBUSTION; ECONOMIZER, ELECTRICAL FOWER GENERATION; FUEL; HEAT; HEATING AND VENTILATION; PULVERIZED,
FUEL, STEAM ACCUMILATORS; STEAM CREST; STEAM ENGINE,
STEAM TURSINE, etc The present article attempts to co-ordinate above references under the following headings: Fuels; Combustion; Boilers and Steam Generators; Mechanical Stokers;
Other Equipment; and Selection of Steam Generatine Equipment.

## DEVELOPMENT OF STEAM GENERATORS

When steam units were first used industrially the boiler was purchased, a brickmason employed to set the boiler in place and a labourer indiscriminately secured to shovel fuel under the boiler to generate enough steam for the process in question. Fuel, labour and material were cheap. It was not then economical to seek refinements in equipment or labour-saving devices; steam demands and pressures were low and in many cases, return tubular boilers answered the necessary requirements. The industrial development of the 20th century caused rapidly increasing demands for power. These were first met by the improvement in the design of steam turbines, and the application of mechanical stokers to the existing boilers. This met the needs for a few years but about 1916 steam turbine units began to increase rapidly in size and in 1030 single turbines of 60,000 kw, were in operation and compound units of 200,000 kw. turbines in course of construction In 1939 power houses containing 770,000 kw. were in operation and power houses designed for 1,000,000 kw output have been projected. In 1920 there were a few stations operating above 250 lb, pressure. In 1939 there were several score of stations operating at over 1,200-1,400 lb. pressure and a few

are now in operation at higher pressures.

With these changes steam boilermakers discarded rule of thumb methods and employed research engineers, metallurgists and various specialists, installed machine tools, and adopted scientific methods of manufacture. It was found at this time that the kind of water introduced into the boiler was of considerable importance; that the superheater should be located in a position that would give a wide range of load with very little change of temperature; that an evaporation of from 13 to 21 lb of steam per square foot of heating surface per hour should be the minimum; that the use of pulverized coal to secure these high ratings was desirable. Air-cooled refractory furnaces to burn pulverized coal at high ratings were tried but it was seen that, with watercooled furnaces, a unit could be designed that would combine economy and efficiency with low maintenance cost and maximum continuous hours of service. With new and larger plants, the question of the best cycle to be used became of paramount importance affecting the boiler, superheater, feed water heater and economizer design. Means were needed to remove free oxygen from water to prevent corrosion. The water entering the economizer was of higher temperature than when exhaust steam alone was used and the temperature of the gases leaving the economizer were too high for the best efficiency. Consequently air preheaters were developed to recover heat from the escaping gases, to provide hot air for drying the coal in the course of pulverization and to preheat the air for combustion before being introduced into the furnace. This cut down the time required for complete combustion and raised the temperature of the furnace

A 4,00,000 kw plant will burn 200 tons of coal per hour and roughly one-tenth of this will be ask which must be removed Ash, in a dry state, is removed by conveyors or by shicing with water A newer development is to melt the ash and to remove as sing Safety consideration, abatement of smoke and noise, consideration of the design of the plant to fit in with surrounding buildings and landscape, were additional problems to be solved IT will be seen then that the problem of generation of steam to meet the requirements of modern industrial civilization has become extremely complex.

#### FUELS

The principal fuels for the generation of steam are coal and oil (see Fuel, Pulverized Fuel, Petroleum, Coal and Coal MINING). There are, however, many localities where there is a limited supply of certain other materials which are sometimes used for fuel Coke breeze is the small size coke and dust which is burned successfully on chain grate stokers Lignites  $(q\ v\ )$  are burned on chain grate stokers and in pulverized form Wood is usually put through a hogger to reduce it to small sizes for greater ease in handling and better burning in the furnace. The furnace must be large to provide sufficient time for complete combustion. Bagasse is the residual sugar cane, left after the juice has been extracted. The furnace is especially constructed for admitting air around its sides The silica in the bagasse runs on to the grate and prevents air coming in from underneath Bonecoal is the name given to coal taken off the top of coal seams and contains a large amount of impurities. Formerly discarded, it is now being burned on stokers and in pulverized form. Anthracite coal is used for household use in the districts adjacent to the anthracite fields. There is, however, a large amount of small sizes and dust that is now being burnt on travelling grate stokers, especially built for this purpose. Natural gas (q.v.), blast furnace gas (q v ), coke oven gas (qv) and producer gas (see GAS MANUFACTURE) are also frequent boiler fuels.

Boilers are used to generate steam from the otherwise wate heat of cement klans, metallurgical furnaces, coke ovens, gas generators and other such processes where high exit temperatures of the products of combustion prevail In the McEwen-Runge process of coal carbonization, the coke in pulverized from served as a fuel for boilers as did also the screened coke residue from the K.S.G process which was burnt on forced draft chain grate stokers.

## COMBUSTION

Combustion within the furnace of a steam generator consists in the chemical combination of the elements of the fuel with oxygen from atmospheric air supplied for that purpose Corresponding to the weights of carbon (C), hydrogen (H), oxygen (O) and sulphur (S) in the fuel fired, the weight of air theoretically required for combustion is given by

$$A = \frac{2 \cdot 67 \, C + 8 \, (H - o/8) + S}{o \cdot 23^2}$$

since atmospheric air contains 23-2% of oxygen by weight. It is necessary to supply "excess air" above this theoretical minimum, however, and "free oxygen" always occurs in the products of combustion. Even with excess air, some combustible will escape unburnt from the furnace and a small amount of carbon monoxide may simultaneously be found in the products of combustion. The unburnt combustible is generally carbon with a corresponding combustion loss of 14,600 B.T.U. per pound. The formation of carbon monoxide (CO) instead of carbon dioxide (CO,) is named "incomplete combustion." One pound of carbon burned completely to CO; liberates 14,600 B.T.U. One B.T.U. but the complete of 
content of the excess air at the temperature of the products of combustion escaping to the stack Leakage of air through the walls of the furnace and boiler setting increases the excess air loss to the stack without effecting, in general, any corresponding gain in combustion efficiency. Considerable saving in fuel may often be made simply by reducing leakage through cracks or openings in bother settings.

For each kind of fuel, type of furnace and method of firing, there is a certain percentage of excess air which results in a minimum loss. The most economical percentage of excess air is determined for any given installation from analyses of the products of combustion, and it corresponds to that percentage of carbon dioxide at which the carbon monoxide amounts to only a few tenths of 1% For hand-fired coal furnaces and older stoker installations with restricted furnace volume, the best carbon diovide percentage is around 12% which represents about 50% excess air. Larger combustion chambers were later employed because it was thereby possible to reduce the excess air below 50% without producing much carbon monoxide. At high operatmg capacities, however, furnace temperatures became so high that slagging of refractory walls and formation of clinkers in fuel beds became excessive. Water-cooled walls have eliminated refractory troubles and permitted the most economical percentage of excess air to be used without reaching excessively high temperatures, so that in some of the most modern steam generator furnaces as high as 15 to 16% of carbon dioxide is attained in daily operation.

With gases and oils, the most economical percentage of carbon dioxide will, in general, be less than mentioned above for cap, although the excess air percentage may be lower by reason of the more intunate mixture of fuel and air that can be obtained with proper burners and furnaces. This is due to the larger percentage of hydrogen in these fuels which combines with oxygen-forming water that is not ordinarily included in analyses of products of combustion.

When burning pulverized coal, thorough mixing in the furnace of the fuel particles with the air is conductive to complete combustion with low excess sir. This may be secured by means of turbulent firing where the coal and air streams impinge upon one another in the furnace, but while the volatile matter may be burnt within a small volume, a much larger furnace must be provided to give time for the fixed carbon particles to burn before they escape from the furnace. Finer pulverization will reduce the unburnt combustible loss at the expense of the use of more power for grinding the coal. For solid fuels burned on grates and stokers, the furnace shape as well as its size is important in securing thorough mixture

Smoke is often taken as an indication of poor combustion, and so it may be. However, smoke is often due to the presence of fine particles of soot resulting from breaking down volatile matter by heating with insufficient air rather than to larger particles of unburnt fixed carbon. Hence a smoking furnace may be working at fairly high efficiency, while one with a clear stack may have a large excess air loss. Smoke may be prevented by using a low volatile fuel such as anthractic coal and codes, or by mixing air with the volatile matter more thoroughly and thereby insuring its complete combustion in the furnace.

Combustion losses are reduced by preheating the air. The maximum permissible preheat temperature is determined by the durability of grates or stoker parts. In pulverized coal firing, the preheat temperature is limited only by the durability of the pre-heater elements. There is an economic relation, however, between the cost of air preheater surface, economizer surface and boiler tube surface, which results in a minimum cost for the complete steam generating unit corresponding to a moderate air preheat temperature between 400° and 500° F.

If all the heat liberated by combustion and carried into the furnace in the preheated air were imparted to the products of combustion, very high furnace temperatures would be reached. Much lower temperatures catually obtain in boiler furnaces due to radiation. Radiation from the incandescent fuel and finness varies approximately as the fourth power of their absolute tem-

perature. With water-cooled walls, over one-half the heat of combustion is absorbed in the furnace by radiation from the incandescent fuel and flames. This radiant heat will fuse any particles of ash which cannot be kept cool by adjacent watercooled surfaces. Hence refractory baffles must be protected by two or more rows of boiler tubes on the furnace side or particles of ash adhering to them will fuse and form large slag masses With pulverized coal firing, ash will melt on the furnace bottom unless cooled below its fusing temperature and protected from radiation by "screen tubes" While the melted ash may be run out of the furnace as molten slag, there is an additional furnace loss in the latent heat of fusion of this slag

Boiler test codes adopted by engineering societies in various countries, define boiler efficiency as the ratio of the heat absorbed by the steam produced per unit weight of fuel burned, to the gross, or upper, heating value of the fuel as determined in a calonmeter where the moisture present in the fuel and formed from the hydrogen therein is condensed to water. In England, efficiencies are often guaranteed as based on the lower heating value, which is equal to the upper heating value minus  $1,050 \times (M+9H)$ , where M=lb. of moisture and H=lb. of hydrogen per lb. of fuel burned and 1,050=latent heat of steam at (W L DE B) atmospheric temperatures.

### BOILERS AND STEAM GENERATORS

Boilers are of the following designs: return tubular, water tube electric steam generator.

Return Tubular boilers consist of a shell 60 in. to ro8 in. in diameter. The shells are made of several plates riveted together with the tubes acting as stay bolts for the heads The gases pass through the tubes. The boilers are limited in size to about 3,000 square feet. This type of boiler is used where small quantities of steam are required, at pressures not exceeding 250 lb. per square inch. It is also used extensively for waste heat in the manufacture of open hearth steel and other processes, in marine work and for locomotives.

Water Tube Boilers are boilers in which the water passes through the tubes and the gases are on the outside of the tubes. One of the main advantages of this type of boiler is safety. The latent heat in hot water under pressure has a particularly destructive effect in case the pressure in the vessel is suddenly released

By confining the water to tubes, the quantity of water in any particular part of the boiler is kept to a minimum and if a tube bursts, the resulting damage will be small. Another advantage is that the size of the unit is limited only by the size of plates available.

This boiler is made in several different classes; straight tubes with box headers and both longitudinal and horizontal drums. straight tubes with sectional headers, and both longitudinal and horizontal drums, bent tubes with vertical and semi-vertical tubes and drums

For box header boilers the headers are formed by riveting together two plates, spaced apart to form a boxlike structure. This construction is usually limited to 10,000 sq.ft. on account of the difficulty of shipping larger plates and to pressures of about 400 lb. per square inch

The straight tube sectional header boiler is substantially of the same general cross-section as the box header except that in some cases there is a greater inclination of the tubes. The headers are made of forged steel and contain one or more vertical rows of tubes. This type of boiler has been built in sizes up to 35,000 sq ft. and can be built larger and for pressures up to 1.800 lb. per square inch.

Electric Boilers.—The electric boiler is used to generate

steam or hot water where a small quantity of steam is required or in larger sizes where electricity can be secured at reasonable rates to improve the load factor of plants

Steam Generators.—The advent of pulverized coal (see PULVERIZED FUEL) crystallized the design of complete steam generating units giving consideration to the proper furnace volume and co-ordination of radiant and convection heating surface, super-

heater, economizer and air preheater. Such construction can be fired by oil, gas or pulverized fuel. It can readily be built for pressures up to 2,000 lb per square inch. The fuel may be introduced at several points and sometimes the burners are located at the top of the furnace with the gases passing downward. In other designs the fuel is introduced at the front wall or at the four corners with the gases passing upward through the furnace, The economizer and fan may be placed duectly back of the convection surface and the fans directly above the air preheater so that the duct work, with its chances for radiation and leakage. is reduced to a minimum. Some steam generator units give efficiencies of 80%

Drums.—When built for pressure of 100 to 350 lb, all boiler drums were constructed of rolled plates formed on bending machines and riveted together. As the pressure increases the plate is necessarily thicker, making it more difficult to form plates and drive the rivets. It is generally accepted in 1030 that riveted drums should be limited to not more than 14 inches Up to 1928 a few boiler drums less than 2 in, thick have been constructed by forge welding In Europe, but not in the United States up to 1929, drums have been constructed of drawn seamless tubes. In 1931 the A S.M E boiler code made permissible the use of autorenous or electric welding for the construction of boiler drums. Prior to 1931 it was customary to construct drums 24 in thick and over of forgings but welded drums are now made up to five inches in thickness.

The joints to be welded are carefully machined before welding and submitted to X-ray examination after welding under rigid inspection. The drums are then annealed to remove stresses.

In the United States the steel for riveted and forge-welded boiler drums must conform with the chemical and physical characteristics given in the ASME. boiler code. Alloy steels with varying percentages of chrome, titanium, molybdenum, and other elements are used to take care of the higher temperatures and to keep plate thicknesses within reasonable limits for high pressure

Large Units .-- For large capacity units, the bent tube boiler has been found to give the most economical results. At low ratings, below 300%, the straight tube boiler has been found to give lower exit temperature but above these ratings the bent tube boiler gives approximately the same and in some cases lower exit temperatures

At high ratings the draft loss of the bent tube boiler is much less. It is customary in designing large boilers to place two bent tube boilers in the same setting and facing each other. With this method of construction, firing is usually done from two sides or from the four corners. The radiation losses are low, the gases are most thoroughly mixed before entering the boiler surface, the unit is compact and the drums are practically one-half the length that would be required for a single unit with firing from one side Single units to deliver 750,000 lb, of steam per hour and double units to deliver over 1,000,000 lb of steam per hour at 1,400 lb. per square inch pressure, and over 900° F. steam temperature, were in operation in 1939.

(See Boiler-Making; Boilers) (T. B. C.)

## MECHANICAL STOKERS

A mechanical stoker is a device for stoking or firing a furnace by mechanical means In its broadest interpretation mechanical stoking would include the mechanical feeding of any kind of fuel to a furnace, but in common usage the term is limited to the firing of solid fuels such as coal and coke The earliest form of mechanical stoker was an endless conveyor with two endless chains situated near the sides of the furnace and engaging sprockets mounted on shafts situated at the front and rear. Transverse grate bars were attached to these chains to form the fuelsupporting surface, one shaft was provided with means for driving the chains and grate so that the top surface moved through the furnace from front to rear. A hopper fixed at the stoker front supplied fuel to the grate and natural or chimney draft provided air for combustion which was admitted through the grate and fuel bed. The speed of the grate was regulated so that the fuel

(C. STR)

was burnt out during its travel through the furnace and the motives and marine boilers. resultant ash and refuse was discharged into a pit as the grate made the return bend around the sprockets on the rear shaft A natural draft chain stoker is applicable to non-coking or free

burning bituminous coals

A modification of this type of stoker provides for the use of forced draft supplied by a fan or blower for admitting the air for combustion. With this provision, higher rates of combustion are made possible, and a wide variety of fuels may be burned successfully including anthracite fines, coke fines, lignite, and free burning bituminous coal

The overfeed, inclined grate natural draft stoker is used to a limited extent for burning bituminous coals at moderate ratings under small boilers The fuel is fed from the hopper usually at the front, to stepped grates which are rocked by mechanical means to impart a downward travel of the fuel during combustion and to deposit the ash and refuse at the rear, on dump trays which are lowered by hand at intervals to discharge the ash into a pit below.

In overfeed stokers of the spreader type the coal is fed from a hopper into the path of rapidly revolving paddles which throw the coal into the furnace where the fines are burnt in suspension and the coarser particles on a grate using forced draft.

Underfeed stokers, as the name suggests, introduce the fuel below the surface of the fuel bed. The volatile constituents of the coal are distilled off and pass up through the incandescent fire where they are rapidly ignited and burned without producing smoke. Forced draft is used with this type of stoker This method of firing finds its greatest field for use with those bituminous coals which during combustion tend to form coke masses that must be broken up to insure uniform fuel bed conditions. Underfeed stokers may be broadly subdivided into two general classessingle retori stokers and multiple retort stokers.

In single retort stokers the coal is commonly fed from a hopper at the stoker front into a centrally situated trough or retort by means of a pusher driven by a steam actuated piston or by an electric motor. In small underfeed stokers a slowly revolving screw or worm is commonly used to feed the coal from the hopper to the retort. Each new charge of coal introduced serves to push an equal volume of fuel out of the top of the retort and onto the grate bars which extend transversely from the sides of the retort. Alternate grate bars are movable and are connected to the stoker drive so as to impart a slight slicing motion which serves to maintain a porous fuel bed, to distribute the burning fuel across the stoker and to carry the ash and refuse to dump trays placed along each furnace side wall. Air for combustion is supplied under pressure by a fan or blower and is admitted to the fuel bed through openings along the sides of the retort and between the grate bars.

The multiple retort underfeed stoker comprises a series of retorts (usually inclined) mounted side by side across the furnace width. Coal is fed from a hopper, fixed at the stoker front, by rams connected to a crank shaft and driven through proper reducing gearing by an electric motor or other means. Secondary rams, situated in the bottom of the retorts, serve to break up the coke masses, to distribute the fuel over the stoker and to deposit the ash and refuse either on dump grates or into a pit at the rear where grinder rolls crush the refuse and discharge it into a pit below. Air for combustion is supplied under pressure by a fan, through nozzles or tuyeres arranged in longitudinal rows between adjacent retorts.

Mechanical stokers are usually controlled by regulators which are set to maintain a predetermined steam pressure and which are actuated by changes in this pressure. A drop in steam pressure causes an increase in stoker and fan speed so that more coal and air are admitted to correct the falling steam pressure. An increase in steam pressure causes a decrease in the amount of coal and air admitted. Stokers so equipped maintain constant steam pressure automatically and are called "automatic mechanical stokers." Mechanical stokers are principally used for firing stationary steam boilers and metallurgical furnaces. However, types have been developed and satisfactorily applied to loco-

## OTHER EQUIPMENT

Superheaters are used to increase the temperature of steam without increasing its pressure. The furnace gases furnish the heat, either in the furnace, among the boiler tubes or in the exhaust to the stack where some lost heat can be recovered. For a discussion of superheaters and superheat see Boilers; Steam Reheaters are used to prevent loss of superheat and the forma tion of moisture when steam is used in turbines. (See Boilers)

Air Preheaters -The exhaust gases coming directly from the furnace or from the economizers are used in air heaters or preheaters to heat the air that is to be used for combustion in the furnace, thus making use of otherwise lost heat. (See Boilers.)

Feed Water Heaters .- Before water fed to a boiler can be converted into steam it must first be heated to the temperature coiresponding to the pressure in the boiler. This feed water is heated in open heaters, closed heaters or economizers, either to that or to a lesser temperature, depending on the plant. The first two types of feed water heaters use live or exhaust steam to obtain heat, the last uses the exhaust gases from the furnaces. ECONOMIZER, BOILERS; ELECTRICAL POWER GENERATION.)

Evaporators and De-aerators are used to supply loss in feed water and to remove the air dissolved in the water in the condenser. (See Electrical Power Generation.)

## SELECTION OF STEAM GENERATING EQUIPMENT

Steam generating equipment may be considered as comprising not only the boiler and furnace but all auxiliaries necessary or desirable from the point of delivery of the coal to the stop valve on the boiler. A proper evaluation of factors which determine the correct selection of the necessary or desired equipment can only be made by an engineer thoroughly familiar with all the factors, their relations and a knowledge of costs, values and economics.

In a modern utility plant the steam end may and frequently does include in addition to the boiler a water-cooled furnacesteam superheaters and re-heaters-mechanical stokers of various types, burners for pulverized coal or oil; economizers and air preheaters; induced and forced draft fans or blowers and their necessary motor or turbine drive; ducts and flues for conducting the air and flue gas to desired points; chimney and dampers; cinder or dust catchers; boiler feed pumps and feed water regulators; soot blowers for the boilers; economizers and air-heaters; condensers; blow down valves; heat inter-changers to abstract heat from boiler blow down; open or closed feed water heaters; deaerators; a feed water treating plant or evaporators.

The complete coal and ash handling system from the railroad siding to the coal bunkers may include a car dumper, track hopper, screens, crushers, magnetic separators, conveyors, skip hoists. locomotive-crane and all equipment necessary for storing and reclaiming coal. If coal is pulverized there will be dryers, pulverizing mills with piping collectors, conveyors, feeders, burners and necessary motors. Ash may be handled by cars, conveyors or by water in sluices or grab buckets. Other auxiliary equipment may include a combustion control system with elaborate inter-locking of the electrical equipment. Pressure and draft gauges, thermometers, steam flow meters and gas analysers, all of the indicat-

ing or recording type, will also be found.

The problem of the selection of proper equipment may be very simply stated. Equipment should be selected that will produce steam at the lowest total cost for the expected life of the plant, with the required reliability. The weight given to various factors will differ in various types of plants. In public utility plants where the fuel cost is about half the total cost of operation greater weight is given to economy, this factor being modified by the cost of fuel. In some industrial plants operating only ten hours per day with cheap coal, first cost may be a major factor. There are certain processes requiring continuity of steam pressure or power in which a failure of either or both for a few minutes may ruin material valued at thousands of dollars. In such cases reliability usually secured by duplication or excess spare capacity should be one of the major factors considered. The total cost of steam generation is made up of fixed or capital costs and operating costs The fixed charges or costs are made up of interest on first cost, taxes, insurance, depreciation or obsolescence The operating costs include fuel; water, maintenance material-repairs; supplies of oil, tools and chemicals; operating labour; maintenance labour; clerical salaries and operating supervision Generally, by increasing the capital cost, the operating cost may be reduced. High efficiency can be obtained by high capital expenditure However, depending on the fuel cost and many other factors, a point is reached where the fixed charges of additional equipment equal the saving obtained by that equipment and any additions beyond that point result in fixed charges in excess of savings.

One of the important factors having a major bearing on economy and in capital costs is the plant capacity factor, sometimes named load factor The capacity factor is the total load per year expressed in any suitable units divided by the rated or normal capacity of the units times 8,760 hours per year or the relation of the actual annual load carried to the annual load if units were operated at normal capacity every hour of the year.

In view of the complexity of the many factors affecting the selection of steam generating equipment and their interrelation it is only possible to list them in their major relations and group these relations as logically as possible. The considerations listed below are the most usual. There may be others peculiar to certain specific problems.

STEAM-HAMMER. Steam-hammers are made in sizes ranging from ½ cwt. to about 12 tons. The size is merely a nominal rating, being the weight of the falling parts-piston, rod, tup, pallet—and takes no account of the pressure of steam which drives the piston down for the blow. As an approximate guide, however, it may be stated that the steam pressure in a 5-cwt. hammer gives a crushing effect on hot iron equal to a load of about 30 tons. Types of hammers are classified in three principal forms, the overhanging with slide, the arch and the Rigby (see drawing). In the last-named there is plenty of clearance space for the smith to manipulate work above and around the

accurately, an advantage in many cases of forging, including that done in dies The arch form has two standards between which the tup is also run in guides, and it is much used for forgework of heavy description, being a very rigid construction. The frame is often built of rolled steel plates and angles instead of cast-iron or cast-steel The operating mechanism of the B, and S Massey hammer shown comprises the stop-valve lever which regulates the quantity of steam admitted to the hammer, and the hand-level that is moved to strike light or heavy blows, or to hold work between the pallets as in a vice, for bending purposes, etc The steam is used expansively, with resulting economy, by the action of the tripper, which begins to close the piston-valve after the tup has moved a certain distance A self-acting valve-gear can be applied to any type of hammer, so as to cause the hammer to work automatically Many special shapes of hammer framings and anvils are built for specific purposes. Control is in some cases effected by a treadle, so that one man can use the hammer. Compressed air may be utilized instead of steam, should it not be convenient to furnish a supply of the latter. The lubricator attached to the side of the frame consists of a hand pump with which

NCE WITH THE MOVEMENTS OF THE HAND LEVER

the cylinder and valves can be oiled without stopping the hammer. To secure efficient results the anvil-block must be of great weight, and supported on a mass of timbering resting on deep concrete or rock. The base also rests on timbers and concrete.

STEAM SHOVEL or NAVVY. A form of excavator which drags a bucket or shovel, at the end of a pivoted arm, from a surface position up to the top of a cutting or other place to be excavated, filling the bucket meanwhile. The mouth has steel cutting teeth or tines for easy penetration. When the bucket is filled, discharge is made into wagons or elsewhere by opening a door at the bottom. The machine is a very powerful modified type of jib crane, specially constructed for fast and severe duty, with a great amount of steel construction, and extra hard parts of manganese steel for those subjected to excessive friction and exposure to grit. The pivoted arm either has a fixed swing from anvil-block, and the piston has a longer stroke and gives more its pivotal point about half-way up the jib, or the swing may be power than corresponding hammers of other types. The over-varied by racking the arm to or iro. As the crane stands still be hanging type hammer has sides cracking down to guide the tup in a succession of cuts the dop for pentation has to be regu-

lated to suit the capacity of the bucket. With the fixed arm design this is done by varying the radius of the 1th, and with the racking arm by the movement of the latter alone Bucket capacity varies from 1 cubic yard to about 15 cubic yards. The drive is by steam (the oldest system) but alternatively may be by petrol or paraffin motor, by electric motors, or Diesel-electric. The lastmentioned possesses the advantage of flexibility similar to the steam drive. e g, it will give a sudden access of power (not possible with a direct Diesel drive) due to the high torque characteristic of an electric motor. Shovels are either mounted on plain wheels, or on railway wheels; or caterpillar tracks are fitted, to transfer the machine as required on any ground Some of the largest shovels are built for "stripping" or removing a deep overburden of earth covering ironstone or coal The biggest machine yet built, a Marion, for this duty weighs 1,400 tons, and carries a 15 cubic yard bucket at the end of an arm 120 feet long. Eight caterpillar tracks sustain the shovel, with hydraulic devices to compensate for uneven ground The three motions, hoisting the bucket, crowding or thrusting it into the cut, and rotating, are performed by separate electric motors. This is similar to the practice in steam shovels, which carry separate engines for the three functions.

Shovels can be adapted to work grabs when this provision is necessary for handling piles of material and loose excavation The dragisne excavator is either a machine solely used for this special kind of excavating, or is a modified shovel, the change being made rapidly. Instead of thrusting a bucket, it drags it towards the machine, being suitable for reclamation, canalization, drainage, foundation work, etc The skimmer scoop acts in a horizontal direction, the jib of the navvy being set parallel with the ground, and the bucket dragged along under it, so that the surface of a road can be torn up Also the loose debris may be scooped up and loaded into a lorry. A back-acting trencher has the bucket arm pivoted at the top end of the jib, the latter being lowered to a suitable distance above the ground. As the bucket is reversed to the normal direction for a steam navvy it is dragged towards the machine excavating a trench, and the machine retreats as the work progresses Narrow and deep trenches can be cut rapidly with this adaptation of the navvy See Excavation. (F. H.)

STEAM TURBINE; see Turbine, Steam.

STEARIC ACID: SEE FATTY ACIDS

STEARIN: see CANDLE.

STEATOPYGIA, the term used of the accumulation of fat on the buttocks, thighs and knees, specially observed among Bushman, Hottentot and Pygmy women It is less common among these men but is recorded fairly often among males of the Bastaards. Statuettes found in Southern France which exhibit these features point to the former existence in Europe of such a race.

STEDMAN, EDMUND CLARENCE (1833-1908), an American poet and critic, was born of Puritan stock at Hartford (Conn ), Oct. 8, 1833. He was rusticated after two years at Yale, and was not allowed to return. In 1871, however, the college conferred on him the B.A. and M.A. degrees, and in 1895 the degree of LLD. Clarence Stedman became connected with the New York Tribune, and in 1860 went to the World as editor, later becoming its war correspondent. A clerkship in Washington formed an interlude, but much of his life was spent in trading on the New York Stock Exchange, of which he edited a history (1905). He edited a volume of Cameos from Landor (with T. B. Aldrich, 1873), A Library of American Laterature (11 vol. 1887-90), The Works of Edgar Allan Poe (with G. E. Woodberry, 10 vol. 1894-95), A Victorian Anthology (1895) and an American Anthology (1900). In addition to a large number of ephemeral reviews, he published Victorian Poets (1875), Poets of America (1885), and The Nature and Elements of Poetry (1892), books which show the poet's critical insight, technical knowledge, and high standards of workmanship. His most enduring place in literature, however, is due to his poetry-the deep serious note of his war lyrics or the whimsical fantasy of "Pan in Wall Street." The title of his rather conventional first book, Poems, Lyrical and Idyllic (1860), sounds the keynote of his work. Always a lover of beauty, he refused to be swayed from his ideals by the April 1701. Steele complained that the reception of The Christian

contemporary popularity of such jeux d'esprit as "The Diamond Wedding" As a result he has to his credit a group of fine and true lyrics such as the "Creole Lover's Song" and some longer poems-Alice of Monmouth; An Idyl of the Great War (1863). The Blameless Prince (1869), and the elaborate commemorative ode on Hawthorne (read before the Harvard Ph. Beta Kappa Society, 1877) He died in New York on Jan 18, 1908.

STEED, HENRY WICKHAM (1871- ), British jour-nalist, was born on Oct. 10, 1871, at Long Melford, Suffolk He studied economics, philosophy and history at Jena, Berlin and Paris universities, and in 1896 joined the staff of The Times as acting correspondent in Berlin, and was appointed correspondent in Rome in 1897 Transferred thence to Vienna in 1902 as correspondent for Austria-Hungary, he remained there until 1913 when he returned to London, and was appointed foreign editor of The Times, m Jan. 1914 In 1913 he published The Habsburg Monarchy. in which the internal condition of Austria-Hungary was critically examined and the possibility of a European war discussed. During World War I, Steed was mainly responsible for the foreign policy of The Times and, in 1918, was chosen to frame the policy of Lord Northcliffe's department for propaganda in enemy countries. He was sent on an official mission to the Italian front where he was authorized by the Allied governments to promise independence to the subject Habsburg peoples In Feb 1919 he was appointed editor of *The Times*, and held this post until Nov 1922. From 1923 to 1930 he was editor of The Review of Reviews. Steed was lecturer on central European history at King's college, Strand, 1925-38, and broadcaster on world affairs in the overseas Service, B B C., 1937-47 His publications include Through Thirty Years (1924), Hitler: Whence and Whither? (1934; 5th ed 1937); That Bad Man (1942), and Words on the Asr, 1938-1945, vol. i (1947).

STEELE, SIR RICHARD (1672-1729), Irish man of letters

in the reign of Oueen Anne, is inseparably associated in the history of literature with his personal friend Addison. The two were born in the same year Steele, the senior by less than two months, was baptized on March 12, 1672 in Dublin. His father, also Richard Steele, was an attorney He died before his son had reached his sixth year, but the boy found a protector in his maternal uncle, Henry Gascoigne, secretary and confidential agent to two successive dukes of Ormonde Through his influence he was nominated to the Charterhouse in 1684, and there first met with Addison Five years afterwards he proceeded to Christ Church, Oxford, and was a postmaster at Merton when Addison was a demy at Magdalen. Their schoolboy friendship was continued at the university, and probably helped to give a more serious turn to Steele's mind than his natural temperament would have taken under different companionship. Without waiting for a degree he volunteered into the army, and served for some time as a cadet "under the command of the unfortunate duke of Ormond" (i.e., the first duke's grandson, who was attainted in 1715). This escapade was made without his uncle's consent, and cost him, according to his own account, "the succession to a very good estate in the county of Wexford in Ireland." He found a patron in Lord Cutts, to whom he dedicated a poem on the funeral of Queen Mary (1695) Cutis took the gentleman trooper into his household as secretary, made him an officer in his own regiment, and ultimately procured for him a captaincy in Lord Lucas's regiment of foot. A duel which he fought with Captain Kelly in Hyde Park in 1700, and in which he wounded his antagonist dangerously, inspired him with the dislike of duelling that he showed to the end of his life. Steele won William III.'s favour (too late to be of practical use) by a timely reference to him in The Christian Hero, his first prose treatise, published in

trying him by his own standard, and would not pass "the least levity in his words and actions" without protest. He therefore determined to clear his character of the charge of undue solemnity by writing a comedy, The Funeral (1701). With this play he began his work of reconciling wit, good humour and good breeding with virtuous conduct which he was afterwards to accomplish in the famous essays in the Tatler and the Spectator In his next comedy, The Lying Lover; or, the Ladies' Friendship (1703), based on Corneille's Menteur, Steele's moral purpose was directly avowed, and the play, according to his own statement, was "damned for its putty." The Tender Husband, an imitation of Molière's Sicthen (in April 1705), was more successful It was seventeen years before Steele again tried his fortune on the stage with The Conscious Lovers, the best and most successful of his comedies, produced in December 1722.

The Tatler and the Spectator .- In 1707 Steele was given the office of gazetteer. The Gazette gave little opening for the play of Steele's lively pen, his main duty, as he says, having been to "keep the paper very innocent and very insipid"; but the position gave him insight into journalism. The Tatler made its first appearance on April 12, 1709. It was partly a newspaper, a journal of politics and society, published three times a week. Steele's position as gazetteer furnished him with special advantages for political news, and as a popular frequenter of coffeehouses he was at no loss for social gossip. He gradually introduced into the Tatler as a special feature essays on general ques-

tions of manners and morality.

Steele was always in want of money He had £300 a year from his gazetteeiship (paying a tax of £45), £100 as gentleman waiter to Prince George, £850 from the Barbadoes estates of his first wife, a widow named Margaret Stretch, and some fortune by his second wife-Mrs Mary Scurlock, the "dear Prue" of his charming letters. But he lived in considerable state after his second marriage, and before he started the Tatler was horrowing money The assumed name of the editor was Isaac Bickerstaff, but Addison discovered the real author in the sixth number, and began to contribute in the eighteenth. The success of the Tatler was established before Addison joined him, and Addison contributed to only forty-two of the two hundred and seventy-one numbers that had appeared when the paper was stopped, obscurely, in January 1711.

Only two months elapsed between the stoppage of the Tatler and the appearance of the Spectator, which was the organ of the two filends from March 1, 1711 to Dec. 6, 1712. Addison was the chief contributor to the new venture, and the history of it belongs more to his life. Nevertheless, it is to be remarked as characteristic of the two writers that in this as in the Tatler Addison generally follows Steele's lead in the choice of subjects. The first suggestion of Sir Roger de Coverley was Steele's although

it was Addison that filled in the outline.

Steele projected various journals in the next years, most of them, such as the Englishman (1733), and the Reader (1714), Town Talk, Tea Table and Chit Chat, very short lived; though the Guardian (1713) had 176 numbers. Steele's most famous political paper, the Plebeian (1718) embroiled him in a controversy with Addison. A pamphlet, An Apology for Himself and his

Writings (1714) is important biographically,

١

Later Life.-The fortunes of Steele as a zealous Whig varied with the fortunes of his party. Over the Dunkirk question he waxed so hot that he threw up a pension and a commissionership of stamps, and went into parliament as member for Stockbridge to attack the ministry with voice and vote as well as with pen. But he had not sat many weeks when he was expelled from the house for the language of his pamphlet on the Crisis, which was stigmatized as seditious. The Apology already mentioned was his vindication. With the accession of the House of Hanover his fortunes changed. Honours and substantial rewards were showered upon him. He was made a justice of the peace, deputy-lieutenant of Middlesex, surveyor of the royal stables, governor of the royal company of comedians—the last a lucrative post—and was also

Hero by his comrades was not so respectful; they persisted in he was appointed one of the commissioners of forfeited estates. and spent some two years in Scotland in that capacity. In 1718 he obtained a patent for a plan for bringing salmon alive from Ireland. Differing from his friends in power on the question of the Peerage Bill he was deprived of some of his offices, but when Walpole became chancellor of the exchequer in 1721 he was reinstated With all his emoluments however the imprudent, impulsive, ostentatious and generous Steele could never get clear of financial difficulties, and he was obliged to retue from London in 1724 and live in the country. He spent his last years on his wife's estate of Llangunnor in Wales, and, his health broken down by a paralytic seizure, died at Carmarthen, Sept 1, 1720

the Tatler (1898).

STEELS, ALLOY. It is almost as hard to draw a clear line of demarcation between "alloy steels" and "steels," as it is between "steel" and "non" Diverse definitions have been set up legally for customs purposes, and commercially for statistical but more especially for pricing purposes. As may be seen in the article Iron and Steel, iron is produced from its ores by commercial processes that leave a number of impurities, either alloyed with it or included as insoluble non-metallic particles (A brief definition of an alloving element or compound is one that is more or less soluble in the major metal and which participates in physical or chemical reactions with changing temperatures and thus modifies the properties ) Carbon (in the chemical compound non carbide. "cementite," Fe<sub>2</sub>C) is the principal alloying element in iron, proportionately increasing its strength and hardness, especially after a correct heat treatment Only a little iron carbide (carbon) is needed to convert iron into a hardenable steel, so a metallographer's definition of carbon steel might well be "a malleable alloy of iron and iron carbide" ("malleable" being inserted to distinguish plain carbon steel from cast iron, which is a non-malleable alloy of the same substances) The article Iron and Steel also explains the necessity for the presence of fractional percentages of the alloying metals manganese and silicon in commercial plain carbon steels, and it is difficult to say, as these incidental elements increase, just where a carbon steel stops and a manganese allow steel (or more briefly, a "manganese steel") and a silicon steel start. Likewise "alloy steel practice" consists of far more than adding alloying metals to the liquid steel. The raw material is selected for a low content of deleterious impunities, the furnace practice is extended to include a careful refining period, additions are made to control the grain size (which, in turn, controls the toughness), all surface defects are cut out of ingots or billets-to mention some of the major differences. It may be said, then, that an "alloy steel is a carefully made steel with sufficient alloying metals added to it to modify usefully the properties of a plain carbon steel" The amount of alloy added is no distinction, it may range from very low (0.10% vanadium) to very high (18% chromium or more).

The earliest alloy steels used those alloys then available; since World War I very useful steels have been developed with alloying metals that were formerly unavailable, even rarities. Chromium alloy steels were made commercially into hard grinding equipment by the American, Baur, in 1865. They made their debut into structures in the main arch members of the Eads bridge (1874) across the Mississippi river at St. Louis (USA), they now enter many steels for machine parts, and the high chromium steels are corrosion and oxidation resistant (see Stainless Steel). Nickel, now the other most common constituent of alloy steels, was first incorporated in steels by the Frenchman, Marabeau; the properties were described in 1889 by the Scot, James Riley. Nickel steel was adopted by the American Navy for armour-plate in 1801; it is said that the first application in the mass production industries was some armour-plate rolled into small bars for bicycle chains. Tungsten is the essential element in the air-hardening tool steel of knighted (1715). After the suppression of the Jacobite rebellion the Englishman, Mushet (1871), the precursor of modern high

speed tools It is also used in magnets and in steels for high temperature, high pressure service (Malybdenum, its chemical cousin, was unavailable until large American deposits began producing in Colorado about 1918. In addition to being a substitute for tungsten, it is now a most important element, in fractional percentages, in engineering alloy steels ) Manganese formed the first high alloy steel, 10% being added by the Englishman, Hadfield, in 1882 to form a very tough steel of unique properties. largely used in places like steam-shovel dipper teeth that must resist tiemendous battering Low manganese steels are the product of 1920-30, and are being substituted in many uses for the more expensive chromium and nickel steels Silscon steels, especially useful for electrical transformers and other equipment, were devised in 1880 by Hadfield. Vanaduem and chromium-vanadium steels were investigated in England by Arnold and J Kent-Smith at the turn of the century, the latter, at Canton, Ohio, U.S.A., in 1907 made the first alloy steel by the open-hearth process for the Ford Motor Co , and this company pioneered the use of alloy steels in mass production Copper, used in fractional percentage for atmospheric corrosion resistance, is a pre-World War product

These eight common elements in various percentages and combinations, to say nothing of an equal number of less commonly used alloying metals, may formulate an infinite variety of steels In the last half-century literature about them has accumulated at an accelerated rate until its mass is now formidable. A group of metallurgists led by the American, Edgar C Bain, has systematized much of the existing information Commercial requirements of both producers and consumers have also demanded a limitation of types The American Society of Automotive Engineers led the way in 1911 by adopting chemical specifications for 7 carbon and 11 alloy steels, a list extended in 1935 to 102. Many large transportation companies and Governments have their own lists, and the total (exclusive of tool steels and high alloy steels) was somewhere in the neighbourhood of 300 in 1939 The scientific classification above mentioned has given logic to the practical conclusion that many of the varieties are interchangeable. However, users are slow to discard a steel that has served well in the past, fits into an existing heat treatment schedule, and is approved by the staff, but economics slowly forces the adoption of the cheapest suitable raw material. This generally means steels of lower and lower alloy content

General Influence of Alloys.—A statement frequently heard is that alloy steels are chiefly valuable because they may be hardened and strengthened by heat treatment without incurring the brittleness associated with hardened plain carbon steel Further it is frequently said that to be economically justified, the alloy steels should be used in the quenched and tempered state. It will be shown below that the true function of alloys in the engineering or machine steels is to get high strength and toughness, or hardness and toughness, simultaneously, either more easily than they can be had in carbon steels, or in sizes and shapes in which they cannot be had in carbon steels. Certain alloys also impart unique properties to carbon steels (such as high chromium for corrosion resistance or high manganese for battering abrasion) but in defence of the plain carbon steel it may be said that high strength, hardness and toughness are not the sole property of alloys. Thus, the intensity of hardening primarily depends on carbon content, and no alloy steel has yet been discovered which can be made harder than properly quenched carbon steel containing 0.75% or more carbon (measured as C-67 by the Rockwell instrument, wherein hardness number is inversely proportional to size of indentation by a loaded diamond point). There are also very strong, tough steel wires for steel cable; these are of high carbon steels, properly cold drawn to high strength; they withstand 225,000lb. per sq.in. before fracture, at which time they have extended 4% in rom of their original length. Since steel is an alloy of iron and iron carbide, the alloys present in it can be located in one or more of three possible phases or micro-constituents: (a) in solid solution in the iron—the alpha iron or "ferrite" (b) combined with carbon, either replacing some iron in the iron with oxygen or nitrogen in non-metallic, insoluble inclusions. Rarely does one alloy act in one way alone, their partition between (a), (b), and (c) depends upon the amount of alloying element or elements, amount of carbon, and the temperature However, some alloys, such as mickel and manganese, act notably to form solid solutions and strengthen the feirite Others act notably to enter and form carbides, as vanadium and molybdenum Aluminium is the outstanding example of the elements in category (c).

Strong Structural Steels .- Alloys falling in category (a) are particularly useful in improving the mild steels used for plates and structural shapes These steels are fabricated by the user as they are delivered to him from the rolling mill, without heat treatment In fact, they must be rather insensitive to heat treatment, else bending, flanging, and especially welding will produce hard regions ruinous to the tools that punch or cut them, or regions lacking in required ductility Extra strength and correspondingly lighter sections, such as are desirable for a long-span bridge or for railway car bodies can, of course, be had by increasing the carbon content, but this aggravates the above troubles of hardness. The alternative is to add alloys that enter into solid solution with the iron and so strengthen the ferrite, which, by the way, is the bulkiest con-stituent of these low carbon steels E C Bain lists, in the order of their influence as ferrite strengtheners, from strongest to weakest, these alloying elements as phosphorus, silicon, manganese, nickel, and that portion of the chromium which is not combined with carbon. Each of them is used and in various combinations in commercial tonnage steels Nickel steel was undoubtedly the first, used for long-span bridges, 34% of that element greatly improving the tensile properties and doubling the impact strength A cheaper alloy, known as "structural silicon steel," is now favoured in America and much used by structural engineers. An early type of such steel, used by constructors of pre-World War I "Mauretania" is also shown in the table, although the British admiralty now prefers the "D-steel" These strong steels, when weldability is important, have very low carbon content. Reductions in section thickness also demand a better degree of corrosion resistance than is afforded by the normal addition of o 20% copper, and phosphorus and chromium have been added to low carbon steels (<0.10% C) for their combination strengthening and ennobling effect American steels much used for railway rolling stock and bus and truck bodies are shown in the last three lines of Table I

Hardenability of Alloy Steels.-Alloys are, of course, of most importance to heat treatable steels. To understand their action it is necessary to know that when steels are heated above their "critical points"—a characteristic range of about 725° to 825° C .- the crystal structure of alpha ferrite is transformed into a new one called "gamma iron" which has far greater solubility for carbide. This high temperature solid solution of the carbides in gamma iron is called "austenite." On slow cooling the reverse action takes place at about the same critical range, and the annealed, fairly soft and ductile steel is reconstituted, except that the process may have refued the grain On more rapid cooling the precipitation of carbide from austemite is delayed-a little time is necessary for the action to incubate and then to proceed to completion-and occurs at a somewhat lower temperature. On rapid cooling, as when quenching a small piece in cold water, austenite is trapped unchanged down to below 150° C. but then changes completely in a second or two to a very hard structure called "martensite," which seems to be alpha iron (ferrite) in which the iron carbide is dispersed in almost molecular particles. This is the essence of the hardening action. (For a fuller account of the metallographic changes see Iron and STEEL.) Plain carbon steels have a low hardenability, in the sense that if a 11in round bar is quenched in cold water only the outer layers of the steel are cooled rapidly enough to transform at low temperature into martensite, the inner core, cooling more slowly, is transformed at high temperatures near the critical into a much softer entity, a coarser mixture of laminated ferrite and carbide. The outer surface may be intensely hard, even the maximum possible for the carbon content of the steel, but the "penetration" of that hardness is low. To harden more deeply the cooling rate at the surface carbide, or forming a special carbide of its own; (c) combined must be faster, so the deeper regions of the steel may cool rapidly

TABLE I -Low Alloy, High Yield Steels for Revoted and Welded Structures

enough to escape the high temperature transformation; even the metal to resist "creep" at high temperature. The American Society most drastic quenching, as in brines or water sprays, may be insufficient for complete hardening. Fortunately, the presence of all the alloying metals except cobalt slows up both the solution of carbides in the austenite on heating, and their precipitation on cooling This means that alloy steels do not need to be cooled nearly so fast in order for the austenite to be "trapped" and transformed at about 150° C into hard martensite. Alloy steels therefore have a higher hardenability. Given an equal quench and an equal sized bar, the alloy bar will harden much more deeply than the carbon steel bar of the same carbon content, or it may be satisfactorily hardened in a much milder quenching bath, as in oil or even in still air, with correspondingly less warpage and danger of cracking As an example, the presence of 11% nickel and 0 60% chromium doubles the hardenability of a 045% carbon steel Bain's list of the relative potency of alloys in this respect follows. Very strong, vanadium; strong, molybdenum and tungsten, moderate, chromium, manganese, silicon; mild, copper, nickel, phosphorus

Toughness of Alloy Steels .- Certain of the alloys have still another beneficial effect-that of refining the grain. According to the laws of crystallography, certain favoured austenite grains should grow at the expense of their neighbours, with the result that the hot steel should become coarser grained with longer and longer stay at higher and higher temperature But first a considerable time is necessary to dissolve complex and sluggish carbides in the austemite, and many seem to have a central particle that resists dissolution, and these refractory particles disseminated through the metal effectually prevent the natural grain growth of the solid solution The advantage is that a fine-grained austenite, when quenched and tempered, has a very desirable degree of toughness. Bain's list of grain refining elements, arranged according to their effectiveness is Titanium (very strong), vanadium, molybdenum, tungsten, chromium, and manganese (mild)

Aluminium, added to the metal in proper small quantity in a properly deoxidized steel, apparently reacts with traces of oxygen and nitrogen dissolved in the steel, and precipitates out as a cloud of insoluble particles in the solidifying steel. These inclusions are even more effective obstructions to austenite gram growth. Such fine-grained steels are popular in America. They are especially useful in low carbon, carburizing steels. In the carburizing operation, machined steel parts can acquire a high carbon skin or case, say o osin, deep in shr exposure to a highly carbonaceous gas at 1,700° F. Even after such a long and high heating the austenite remains so fine in grain size that the parts can be quenched direct from the carburizing heat to harden the high carbon case, secure in the fact that the inner portions remain fine grained and tough.

The toughness of alloy steels, or the ability to absorb rapid blows, is also improved by the circumstance that those containing the carbide-forming elements listed two paragraphs above may be tempered or reheated after quenching to considerably higher temperatures than carbon steels of the same carbon content and still retain the hardness of the plain carbon steel, quenched and tempered at a lower temperature. Evidently the sluggish diffusion of alloying elements, trapped in solution in the freshly quenched martensite, requires a higher temperature and a longer time before the complex-carbides can re-form, in comparison with the formation of simple iron carbide (Fe<sub>2</sub>C) by diffusion of trapped carbon. Since the toughening due to tempering is largely a matter of relieving the high internal stresses in freshly quenched steels, and since this stress-relief is greater at higher temperature, it can be seen why alloy steels may give, after proper heat treatments. metal that is strong, hard and unusually tough

These sluggish changes in the complex alloy carbides are utilized in steels for high temperature, high pressure equipment Stable carbides enable the hot

of Mechanical Engineers' Boiler Code has tentatively proposed a working stress of 5,750lb. per sq in for plain carbon steels at 900° F, and 10,000lb per sq in (nearly double) for the same steels plus o 50% molybdenum.

Interchangeability of Alloy Steels.—From what has gone before one might properly conclude that a definite combination of strength, hardness, and toughness might be secured from any one of a large number of alloy steels, provided the size was not too large and the heat treatment properly adjusted. How true this is may be proved by transmission drive shafts in six leading American automobile plants. One firm uses o 60% carbon steel, oil quenched; another 1 75% nickel, 0 25% molybdenum, 0 20% carbon steel, carburized, two others use 1% nickel, 0 60% chromium, o 75% manganese, o 40% carbon steel, oil quenched, another uses o 25% carbon, o 80% manganese, o-20% molybdenum steel, carburized, and the last one uses 1% chromium, 0.75% manganese, o 35% carbon steel, oil quenched

It will also be noted that the above alloys are all low alloys, and this represents an undoubted trend in alloy practice, both in England and America, especially in the smaller sizes of forgings or machined gears where adequate penetration of hardness may be secured by not too drastic quenches. For the massive forgings, steels with higher content of alloys, and long continued heat treatments to permit the sluggish reactions, are still necessary

Gear Steels,-As a specific application of the above general principles, the problems of gear manufacture may be considered. for the choice of steel and its treatment depends very intimately on the design of the part and its intended duty. Large gears for rough service are frequently cast direct in gray iron or low carbon steel, but the irregularities in dimensions of wheel and gear teeth are such that speed and power transmitted must be relatively small, life is short and noise is great. An improvement as to accuracy and wear resistance consists in welding together a gear "blank" of appropriate shapes, the rim into which the teeth are to be cut being of medium carbon steel; after machining, the teeth surfaces are individually hardened by passage of an enveloping flame from oxy-acetylene torches, followed closely by quenching jets. In comparison with these, the high duty herringbone gear sets used on turbine-driven propeller shafts are marvels of precision; they are of cast alloy steels heat treated to relieve internal stresses and insure dimensional stability as well as induce as much hardness for wear resistance as is consistent with machinability. This hardness limit is somewhere about C-40 (Rockwell scale). The steels contain 0-50 to 0.60% carbon, but alloys are necessary to give proper depth of hardening and fine grain size Examples are 1.25% manganese plus one or more of the elements molybdenum (0:30%), nickel (1%), chromium (0.5%) and vanadium (0.15%). In large sections a quenched and tempered chromium-nickel-molybdenum cast steel will have the following physical properties indicating medium strength and hardness with great toughness. Yield point 105,000lb. per sq.in.; tensile strength 135,000lb, per sq in.; elongation 20% in 2in.; reduction of area 64%; Rockwell hardness C-32

In the smaller gears utilized for automobile transmissions and rear axle drives the mass effect or deep hardening effect is not so necessary. Requirements are very diverse and exacting, and these, together with the desire to save weight, and therefore to have gears as small as possible, have preserved this field to alloy steels. The original conception of a gear tooth was that it should have a hard surface to resist wear and a tough centre or core to

resist impact Following this idea, gears were cut from annealed blanks, forged from low carbon alloy steels (less than o 20% carbon), the machined gears were then carburized by heating in contact with carbonaceous solids or gases until their surfaces had come up to 0 90 or 1 00% carbon for a depth of 0-030 to 0 050in (about % the thickness of the tooth at the base) The subsequent heat treatment was at times rather intricate, consisting of a high temperature quench to refine the low carbon core, a lower temperature quench to harden properly the high carbon surface, and a tempering to improve the toughness. Steels widely used in this way included those shown in Table II. Representative properties of the core after an oil quench suitable to harden the carburized case are as shown Evidently here is a variety of steels suitable for any designer's requirements, where he balances cost (alloy content, machinability, and heat treatment schedule) against strength desired to carry the loads on the gear tooth, and toughness against impact loadings Probably the ultimate in properties, disregarding cost, is a so-called "armour plate" analysis with carbon 0 10%, nickel 4%, and chromium 1 5%, used for aircraft, heavy duty truck, and bus gears Its heat treatment is quite complicated, including an oil quench from 850° C and draw at 650° to make the forgings machinable, 24hr carburizing of machined gears at 940° F, annealing at 730° F and cooling slowly (8ohr ) to soften the case so the teeth can be finish-machined a few thousandths to remove distortion. The gears are then hardened by oil quenching from 760° C and tempering at 150° C

Carburizing all these analyses gives an outer surface containing 0 90 to 1.0% carbon, and since surface hardness of the quenched gear depends on carbon, rather than alloy, content, all of these teeth can be made "file hard"—that is, too hard to be bitten by a testing file whose hardness is Rockwell C-65 Experience has also proven that maximum resistance to abrasion is secured from such high carbon cases on steel containing chromium or molybdenum carbides. One serious objection to the practice outlined above is the cost of heat treatment after carburization, and this has been attacked by the use of the fine-grained steels which may be quenched direct from the carburizing heat and still possess a fine structure and considerable toughness. This practice was fairly common with the 1% chromium, o 15% vanadium steels, which are inherently fine-grained, before the special fine-grained steels were regularly produced by the steel mills One much used type is the nickel-molybdenum steel shown in the last line of Table II

Table II — Properties of Low Corbon Cores of Gent Teeth Carburized and oil quenched from temperature shows

<sup>\*</sup>Water quench

High speed transmission gears in automobiles must operate without much noise, and this requires a degree of accuracy of shape on the order of o-0005 inch. Warpage increases with the depth of carburization, so shallow cases were tried to give quieter gears. This was successful, but the hard case now tended to flake off, due to fatigue failure of the weaker low carbon metal at junction of case and core 'To strengthen this metal it has been necessary to increase carbon content, and the result is that in 1940 American automobiles the great majority of transmission gears are of steels that used to be called "oil quenching gear steels," high enough in carbon and alloy to quench to a file hard surface without carbunzation. An upper carbon limit is set by the demands of reasonable machinability. Whereas the old oil quenched gears were heated in molten lead for quenching (in order to avoid any trace of decarburized soft skin), the more modern practice is to hold them in a cyanide bath at 815° C. for about 25min. which is enough to induce a o co2-in case of carbides and nitrides, exceedingly hard and wear resistant, or to heat them in a controlled gas of carburizing nature A representative steel would contain 0.45% carbon, 1.25% nickel, 0.60% chromium. After the above quenching from cyanide and a 2-hr. draw at 235° C the core would have a tensile strength of 275,000lb. per sqin, and a correspondingly high fatigue strength. After such treatment the involute errors seldom would amount to 0 0004 inch It is seen that the result is a gear with high surface hardness to resist wear, high core strength just under the case to resist fatigue failure (flaking or pitting of the surface), high strength to carry the normal loads, moderate cost of the steel with its moderate alloy content, cheap heat treatment, and a quiet running gear "A soft, tough core to resist impact," once a prime requisite of a successful gear, is not contained within these specifications, as it has become amply evident that if design and shape are correct, a transmission gear set will operate normally without much impact Toughness is achieved by fine gram size rather than high tempering after quench; indeed, tempering is done at the minimum temperature to avoid letting down the hardness at the surface. Other 0.40 to 0.50% carbon fine-grained steels widely used in this improved practice con tain 1.75% nickel and 0.25% molybdenum, 1% chromium; 1% chromium with 0 18% vanadium. Here is a good example of that interchangeability of alloy steels mentioned in the preceding section, choice may depend more on personal preference than on demonstrated advantages

Austentité Steels.—Hadfield's cast 10% manganess steel, discovered in 1882, was remarkable in that it did not harden on quenching. It is, in fact, an austentic alloy, in the sense that the expected change from austenite solid solution to hard martensite does not occur at 200° C but the quenched austentie sysstable at room temperature Cobalt, but especially nickel, has similar effects One result of this is that the most useful of the stainless steels, known as 18-8 and containing 18% chromium and 8% mickel, su unhardenable by quenching

One characteristic of these commercial austenitic steels is that the austenite is not entirely stable. The small plastic movements in high manganese steel, associated with battering or attempted cutting, permit the martensitic reaction to occur in those restricted regions, causing intense hardness-hence their wear resistance in rough service. This is a favourable reaction, but many of the 18-8 steels are put into petroleum stills operating between about 450° and 850° C., and this temperature gives enough thermal agitation to the atoms so that chromium carbides form from the austenite solid solution, unfortunately not in a cloud throughout the mass to "key" and strengthen the metal, but localized at the gram boundaries, seriously depleting the surrounding matrix of its chromium necessary for corrosion resistance. This detenoration of 18-8 (even by the heat of welding) is prevented by introducing minor amounts of strong carbide-forming elements, like molybdenum, titanium or columbium. The latter two, especially, form carbides that are so insoluble in austenite that they act as mert non-metallic inclusions (See also Iron and Steel: Alloys: and the various types of steels under their own headings.)

Binitography.—Edgar C. Ban, The Alloying Elements in Steel (1939), Sir Harold Carpenter and J. M. Robertson, Metals (vol II, 1939). Comprehensive monographs critically appraising the literature on the various alloys are being issued by Alloys of Iton Research, New York.

STELION, a borough of Dauphin county, Pennsylvania, US, 3 mi. S.E. of Harrisburg, on the Susquehnan river; served by the Pennsylvania, the Reading and the Steelion and Highspire railways. Pop. was 12,654 in 1950 and 12,115 in 1940. It has vast steel works and various smaller manufacturing industries, and there is a large limestone quarry within its limits. A town called Baldwin was laid out there in 1866, and the present name was adopted for the borough in 1880.

STEEL WOOL, a mild abrasive commonly used to clean or polish metals and metallic objects. It is of great practical use in the japanning, plating and moulding rooms of factories. In rubbing down metallic articles to attain a fine finish, steel wool achieves much the same results as purnice Steel wool is also used to clean rusty and turnished hollow-ware STEELYARD, MERCHANTS OF THE, Hansa merchants who settled in London in 1250 at the steelyard on the riverside, near Cosin lane, now Ironbridge Wharf Henry III. in 1259, at the request of his brother Richard of Cornwall, king of the Romans, conferred on them important privileges, which were confirmed by Edward I. It was cheefly through their enterprise that the early trade of London was developed, and they continued to flouish till, on the complaint of the Merchant Adventurers in the reign of Edward II, they were deprived of their privileges. They succeeded in maintaining a footing in London till 1597.

STEEN, JAN HAVICKSZ (1656-1679,) Dutch subject-painter, was born at Leyden in 1626, the son of a brewer According to Houbraken he studied under Nicolas Knupfe, a German artist, at Utrecht, and under Jan van Goyen, whose daughter he married in 1649 In November 1646 he enrolled himself as a studient of the university at Leyden and in 1648 he was one of the founders of the Guild of St. Lukie in that city. He sestited at The Hague in 1649, and at Delft in 1654. In 1657 he is said to have been a hrewer at Delft. He is repeatedly mentoned in documents in the Delft archives during 1656-57. He was a resident of Haarlem during the years 1661-69. He then moved to Leyden, where he received permission to open a tavern in 1672. In 1673 he took a second wife, Maria van Egmont, the widow of a Leyden bockseller. He died at Leyden Fe S, 1679.

The works of Jan Steen are distinguished by correctness of drawing, adminable freedom and spirit of touch, and cleamess and transparency of colouring. But their true greatness is due to their intellectual qualities. In the wide range of his subjects, and their dramatic character, he surpasses all the Durch figurepainters, with the single exception of Rembrandt. His productions range from the stately interiors of grave and wealthy critizens to tavers scenes of joility and debanch. He painted chemists in their laboratories, doctors at the bedside of their patients, cardparties, marriage feats—even religious subjects, though in these he was least successful His rendering of children is especially delightful. Portraits from his brush are comparatively yare.

The National gallery contains three pictures by Jan Steen, of which the "Music Master" is the most important, and other excellent examples of his art in England are preserved in the Royal, the Bute, and the Northbook collections, at Apaley House and Bridgewater House, and in the galleries of The Hague, Amsterdam, and the Hermitage, St. Petersburg (Leningard). A remarkably fine example of his work is the "Grace Before Meat" in the collection of Charles Morrison, London.

STEENKIRK or STEENKERKE, a village in Belgian province of Hamaut, on the river Senne, pop. (1939) 494; battle of Steenkirk (Steinkirk, Estinkerke) fought here July 23-Aug. 3, 1692 between Allies (see GRAND ALLIANCE, WAR OF THE) under William III of England and the French commanded by the duke of Luxemburg. Previous to the battle the French army lay facing north-west, with its right on the Senne at Steenkirk and its left towards Enghien, while the army of William III was encamped about Hal. William, seeing the opportunity of surprising a part of the enemy's forces and having forced a detected spy to give Luxemburg misleading news, set his army in motion before dawn on Aug. 3 to surprise the French right about Steenkirk. The advanced guard, mainly English and Danish infantry, under the duke of Württemberg, deployed close to the French camps ere Luxemburg became aware of the impending blow; at this moment the main body of the army farther back was forming up after the passage of some woods. When the fight opened, Luxemburg was completely surprised, and could do no more than hurry the nearest foot and dragoons into action as each regiment came on the scene. But the march of the Allies' main body had been mismanaged; while Württemberg methodically cannonaded the enemy, waiting for support and for the order to advance, the Allies' main

body, which had marched in the usual order, one wing of cavalry leading, the infantry following, and the other wing of cavalry at the tail of the column, was being hastily rearranged in rear. A few battalions only had come up to support the advanced guard when the real attack opened (1.230). The advanced guard had already been under arms for mue hours, and the march had been over bad grounder that when the real three three the second of the secon

it The English and Danes stubbornly advanced, the second and third lines of the French infantry giving ground before them, but Luxemburg was rapidly massing his whole force to crush them, and meanwhile the confusion in the allied main body had reached its height. Count Solms, who commanded it, ordered the cavalry forward, but the mounted men, scarcely able to move over the bad roads and heavy ground, only blocked the way for the infantry. Some of the English foot, with curses upon Solms and the Dutch generals, broke out to the front, and Solms, angry and excited, thereupon refused to listen to all appeals for aid from the front. No attempt was made to engage and hold the centre and left of the French army, which hurried, regiment after regiment, to take part in the fighting at Steenkirk. William's counterorder that the infantry was to go forward, the cavalry to halt, only made matters worse, and by now the advanced guard had at last been brought to a standstill At the crisis Luxemburg had not hesitated to throw the whole of the French and Swiss guards into the fight, and as, during and after this supreme effort, more and more French troops came up, the Allies were driven back, contesting every step against weight of numbers. Those troops of the main body, foot and dragoons, which succeeded in reaching the front, served only to cover and to steady the retreat of Württemberg's force, and, the coup having manifestly failed, William ordered the retreat. The Allies retired as they had come, their rear-guard-of grenadiers from the British regiments-showing too stubborn a front for the French to attack. The latter were indeed in no state to pursue. Over eight thousand men out of only about fifteen thousand engaged on the side of the Allies were killed and wounded, and the losses of the French out of a much larger force were at least equal. Contemporary soldiers affirmed that Steenkirk was the hardest battle ever fought by infantry.

STEEPLECHASING: see Honese Racing and Beedding.
STEER, PHILIP WILSON, O.M. (1860-1942). English painter, born at Birkenhead. He was trained at the Gloucester school of art and afterwards in Parns at the Académic Julan, and in the École des Beaux Arts under Cabanel. After 1836, before which date he had shown three pictures at the Royal academy, practically the whole of his work was seen in the exhibitions of the New English Art club. In his early work he appears as an adherent of the French Impressionist movement, and as a teacher at the Slade school he exercised an important influence on the development of English art. His figure subjects and landscapes show great technical skill. He ded March 27, 1942.

STEEVENS, GEORGE (1736-1800), English Shakespearian commentator, was born at Poplar on May 10, 1736, the son of an East India captain, afterwards a director of the company He was educated at Eton and at King's college, Cambridge Leaving the university (1756) without a degree, he settled in chambers in the Temple, removing later to a house on Hampstead Heath, where he collected a valuable library, rich in Elizabethan literature. He walked from Hampstead to London every morning before seven o'clock, discussed Shakespearian questions with his friend, Isaac Reed, and, after making his daily round of the booksellers' shops, returned to Hampstead. He published in 1766 reprints of the quarto editions of Shakespeare's plays, entitled Twenty of the Plays of Shakesbeare, . . Dr. Johnson suggested to him the preparation of a complete edition of Shakespeare. The result, known as Johnson's and Steevens's edition, was The Works of Shakespeare with the Corrections and Illustrations of Various Commentators (10 vols., 1773), Johnson's contributions to which were very slight. This early attempt at a variorum edition was revised and reprinted in 1778, and further edited in 1785 by Isaac Reed; but in 1793 Steevens, who had asserted that he was now a "dowager-editor," was persuaded by his jealousy of Edmund Malone to prepare an edition of 15 volumes. He made somewhat reckless emendations, but the edition showed a wide innovelage of Elizabethan Hierature. Steevens was one of the foremost in exposing the Chatterton-Rowley and the Ireland forgreiss. He wrote an entirely fictitious account of the Java supstree, derived from an imaginary Dutch traveller, which impose on Erasmus Darwin, and he hoazed the Society of Antuquises with the tombstone of Hardicanute, supposed to have been ding up in Kennington, but really engraved with an Anglo-Sxon inscription of his own invention. He died at Hampetead on Jan. 22, 1800. A monument to his memory is in Poolar chanel.

Steevens's Shakespeare was re-issued by Isaac Reed in 1803, in 21 volumes, with additional notes left by Steevens. Thu, which is known as the "first vanorum" edition, was reprinted in 1813 Steevens's notes are also incorporated in the edition of 1821, or low by Edmund Malone and completed by James Boswell the younger

STEEVENS, GEORGE WARRINGTON (1869-1902). English journals, was borm et Sydenham, near London, on Doc 10, 1869, and was educated at the City of London school and Balliol college, Cofford, of which he was a school and Balliol college, Cofford, of which he was a school. In 1839, he was elected a fellow of Pembuoke college, Cofford. In September 1899 he went to South Africa and joined Sir George White's force in Natal as war correspondent, being subsequently besiged in Ledysmith Reided during the siege, of enterie fever, on Jan. 15, 1900. The articles he had sent home from South Africa were published posthumously in a volume called Prom Capetons to Ladysmith (1900). Another of his most interesting books was With Kutchemer to Karbosom. Steewess had a remataballe gift of seizing the saltent facts and principal characteristics in anything he washed to describe and putting them na varied may supplied the saltent facts and principal characteristics in anything he washed to describe and putting them na varied whem na varied whem na version washed to describe and putting them na varied whem na varied whem na varied whem na varied whem na varied to describe the control of the control

wasset to describe and putting tnem in a vivid way.

\*\*STEFANIE, BASSO NAEBOR or CHUWAHA, a lake of East Africa, lying in 37° E, between 4° 15° and 5° N., and measuring some 40 m. by 15. It is the southermost and lowest (1,856 ft,) of a series of lakes which he in the northeasterly (1,856 ft,) of a series of lakes which he in the northeasterly (1,856 ft,) of a series of lakes which he in the northeasterly (1,856 ft,) of a series of lakes which which have the series of the lakes which have no outlet, varies greatly according to the amount of water brought down by its principal feeder, the Dules, which enters at its north end, being there a rapid stream 50 yd wide and 3½ ft. deep.

Lake Stefanie was discovered by Count Samuel Teledid in 1881.

Lake Stefanie was discovered by Count Samuel Telekt in 1881, and has since, with others of the series, been explored by Donaldson Smith, V. Bottego, M. S. Welby, Oscar Neumann, Arnold Hodson and others. An agreement of 1907 with Great Britain recognized the lake as within the Abyssinian empire.

See Geographical Journal (Sept. 1896, Sept. and Dec. 1900, Sept. 1901, Oct. 1902, July 1922), L. von Hohnel, Discovery of Lakes Rudolf and Stefanne (1894); L. Vannutelli and C. Citerni, L'Omo (Milan, 1899); British War Office map, Africa, 12,000,000 (1924).

STEFANSSON, VILHJALMUR (1879- ), Arctic explorer, was born on Nov. 3, 1879, at Arnes, Manitoba, Canada, of Icelandic parents. He graduated from the University of Iowa and later studied theology and anthropology for three years at Harvard university. After two archaeological voyages to Iceland in 1904 and 1905 he turned to arctic research and had by 1928 spent altogether 10 winters and 13 summers in scientific work north of the polar circle. In 1906-07 he was ethnologist of the Leffingwell-Mikkelsen expedition on the north coast of Alaska and at the mouth of Mackenzie river; in 1908-12 he commanded an expedition on which he discovered certain Eskimo groups and visited others who had not seen a white man for half a century. From 1913 to 1918 he commanded an arctic expedition under the auspices of the Canadian government. During more than five years continuously north of the Arctic Circle (the longest arctic expedition on record) he explored vast regions north of Canada and Alaska, sometimes sledging for months over moving ice, accompanied by two or three companions and living exclusively by hunting. He discovered between 1915 and 1917 the islands now known as Borden, Brock, Meighen and Lougheed, and several smaller islands. In 1918 his then second in command, Storker Storkerson, taking charge while Stefansson was ill with typhoid fever, explored by sledge, with four companions, the Beaufort sea north of Alaska. They were absent from shore about eight months, during six of which they were encamped, and lived by hunting, on a floe more than five miles in diameter while it drifted with them 450 mi. over a previously unexplored ocean from 1 mi. to 3 mi. deep They found an abundance of seals everywhere, had therefore plenty of food and fuel, suffered no hardships, and reported on their return that they felt sure they could have spent several years on this floe safely. This confirmed the conclusions of all the previous sledge journeys of the expedition over the moving ocean ice: that seal life, and therefore probably other water life, does not necessarily decrease, as was previously beheved, farther north in the arctic. Stefansson laid stress on the economic value of the arctic regions, chiefly as meat-supplying countries through cultivation of the domestic reindeer and domestication of the ovibos or musk ox. In 1932 he became adviser on northern operations for Pan American Airways, During World War II he served the U.S. government in an advisory capacity, surveyed defense conditions in Alaska and prepared reports and manuals for the armed forces.

His principal publications are. My Life with the Eshimo (1913); The Friendly Arctic (1921), The Northward Course of Empire (1922); Hunters of the Great North (1922), The Adventure of Wrangel Island (1926); The Standardization of Error (1927); Unicolved Mysters of the Arctic (1938); Greenland (1942); Arctic Manual (1944).

STEFFANI, AGOSTINO (1653-1728), Italian ecclesiastic, diplomatist and musical composer, was born at Castelfranco on July 25, 1653 At a very early age he was admitted as a chorister at St. Mark's, Venice. Count Tattenbach took him in 1667 to Munich, where his education was completed at the expense of Ferdinand Maria, elector of Bavaria, who gave him a court appointment. He was sent in 1673 to study in Rome, where Ercole Bernabei was his master, and among other works he composed six motets, the original manuscripts of which are now in the Fitzwilliam Museum at Cambridge. On his return to Munich in 1674. he published his first work, Psalmodia vespertina, a part of which was reprinted in Martini's Saggio di contrappunto in 1674 In 1675 he was appointed court organist. The date when he was ordained priest, with the title of Abbate of Lepsing, is not precisely known. Steffani's first opera, Marco Aurelio, which was written for the carnival and produced at Munich in 1681, was followed by other works now lost. In 1688 he became Kapellmeister at the court of Hanover, where he made many friends. He wrote for the opening of the new opera house in 1680, an opera called Enrico il Leone, which was produced with extraordinary splendour. For the same theatre he composed La Lotta d'Ercole con Achilleo in 1689, La Superbia d'Alessandro in 1690, Orlando generoso in 1691, Le Rivali concordi in 1692, La Libertà contenta in 1693, I Trionfi del fato and I Baccanali in 1695, and Briseide in 1606. Elevation of Ernest Augustus to the electorate in 1602 led to difficulties with the various German courts; Steffani was sent round as an envoy in 1696 and as a result received from Innocent XI the bishopric of Spiga for his services in securing privileges for Hanoverian Catholics. In 1698 he was sent as ambassador to Brussels, and after the death of Ernest Augustus in the same year he entered the service of the elector palatine, John William, at Dusseldorf, where he held the offices of privy councillor and protonotary of the Holy See.

Steffani did not accompany the elector George to England; but in 1724 the Academy of Ancient Musick in London elected him its honorary president for life; and in return for the compliment he sent the association a magnificent Stabat Mater, for six voices and orchestra, and three fine madrigals. The manuscripts of these are still in existence, and the British museum possesses a very fine Confitebor, for three voices and orchestra, of about the same period. All these compositions are very much in advance of the age in which they were written; and in his operas Steffani shows a remarkable appreciation of the demands of the stage. Notable too are his beautiful chamber-duets, which, like those of his contemporary Carlo Maria Clari (1669-1745), are chiefly written in the form of cantatas for two voices, accompanied by a figured bass. The British museum (Add. MSS. 5,055 seq.) possesses more than a hundred of these compositions, some of which were published at Munich in 1670. Steffani visited Italy for the last

time in 1727 He died at Frankfurt on Feb. 12, 1728.

Steffini stands somewhat apart from contemporary Italian composers (e.g., Alessandro Scarlatt) in his mastery of instrumental forms. His opera overtures show a combination of Italian suavity with a logical conciseness of construction which is due to French influence. His vocal music and his famous duelst are hefore to those of Scarlatti, but his instrumental music is historically important as a factor in the artistic development of Handel.

STEFFEN, ALBERT, Swiss novelist and dramatist, was born at Murguntal (Canton Aargan) on Dec. 10, 1884. He is an unaginative, spiritual, mystical and idealistic writer, showing little of the concrete and disciplined methods that are so characteristically Swiss. His nearest spiritual kunsman is, perhaps, Dostoievel (q.n.). His special quality reveals itself in his novels, such as (q.n.); he has also something in common with Carl Spiritual (1912). His special quality reveals itself in his novels, such as Grad, alone, und Weresheek (1907), Due Backinsmung der Rohest (1912), Due Rechte Liebhaber des Schickkals (1915), Söyligh Meriana (1917) and Die Erneuerung des Bundses (new ed. 1915); in his shorter stones, such as Die Heilige mit dem Fusche (1913) and Verhäugusse (1927); in his plays, such as Das Vergett (1924) and Due Tohef des Generalistabs (1927); and nib sessays, such as Das Versiss im Lebon des Kunstlers (1922), Der Kunstler wuischen Westen and Osten (1925) and Begegnungen mit Rudolf Steiner (1926).

STEFFENS, HENRIK (1733-1484), German philosopher, of Norwegian extraction, was born on May a, 1773, at Stavanger He studied in Germany, and began to lecture at Copenhagen in 1760. His lectures were appreciated by Grundriys and Oelhen-schläger, but the authorities regarded them with disfavour, and Steffens removed to Germany, where he fought in the Napolonici wars on the German side. He was professor of physics at Breslau (1811-22) and at Berlin (1812-43). He died in Berlin on 18-013, 1248, Steffens was the friend and adherent of Schelling and Schleemracher. He had been the start of Schelling and Schleemracher. He had been to be start of the start

See M. Tietzen, Zur Erinnerung an Steffens (1871); Petersen, Henrik Steffens (1884); W. Dilthey, Leben Schleiermachers (1870). STEFFENS, LINCOLN (1866-1936), American journalist and political philosopher. In 1901, after graduate study in Germany and newspaper experience in New York, Steffens became managing editor of McClure's Magazine Here he published the influential articles later collected as The Shame of the Cities For ten years he was the leading figure among the writers whom Theodore Roosevelt called muckrakers, but he was more concerned with the causes of corruption than with specific reforms. and he became a student of revolution, first in Mexico and then in Russia, Barred from many American magazines by his unorthodoxy during and after World War I, he lived quietly and obscurely in Europe during the 1920s, pondering his experiences and observations. His conclusions finally found expression in his autobiography, which had a great success when it appeared in 1931. Although he supported many communist activities in the depression years of the early 1930s, he remained essentially a pragmatist, preferring to ask questions rather than to answer them. His characteristic achievement, both as muckraker and as autobiographer, was in persuading readers to examine for themselves the character of contemporary civilization.

STEGANOPODES or PELICANTFORMES, an order of birds characterized by the fact that the hind toe is united to the second toe by a web. Most species are gregarious and live on fishes; The order includes the pelicans, commants, gannets, shake/birds, frigate birds and tropic birds (qq.w.).

STEGOCEPHALIA, a term often applied to Palaeozoic and Triassic amphibians with solidly roofed skulls, mainly members of the Labyrinthodontia, (See AMPHBIA.)

STEGOSAURUS, the name given to a type of dinosaur

١

found in the late Jurassic of North America. The name (plated haard) refers to the armament of the reptile in the shape of a paired row of bony plates extending upward along the length of the back; the tail bore two pairs of bony spakes. Stegosturus was an inoffensive, small-headed vegetarian with a maximum length of 30 ft. The hind legs are much longer than the fore, suggesting a descent from bipedial ancestors. (See ReprillES; DINOSAURIA.)

(A. S. RR.) STEIBELT, DANIEL (c. 1764-1823), German pianust and composer, was born at the earliest in 1764 or 1765 in Berlin. He was indebted to the crown prince Frederick William for his musical education. Very little is known of his artistic life before 1700 when he settled in Paris and attained great popularity as a virtuoso by means of a pianoforte sonata called La Coquette, which he composed for Queen Marie Antoinette; his dramatic opera entitled Roméo et Juliette, produced at the Théâtre Feydeau in 1793, was equally successful. In 1796 Steibelt moved to London, where his pianoforte playing attracted great attention. In 1798 he produced his concerto (No. 3, in E flat) containing the famous "Storm Rondo"—a work that ensured his popularity In the following year Steibelt started on a professional tour in Germany; and, after playing in Hamburg, Dresden, Prague and Berlin, he arrived in May 1800 in Vienna, where he challenged Beethoven to a trial of skill. His discomfiture was complete and he retired to Paris, living alternately in that city and London during the next eight years. In 1808 he was invited by the emperor Alexander to St. Petersburg, succeeding Boseldieu as director of the royal opera. in 1811. Here he resided in the enjoyment of a lucrative appointment until his death on Sept. 20, 1823.

Besides his dramatic music, Steibelt left behind him an enormous number of compositions for the pianoforte. His playing, though brilliant, was wanting in the higher qualities which characterized that of his contemporaries, John Cramer and Music Clementi: but he was gifted with talents of a high order, and the

reputation he enjoyed was fully deserved.

STEIN, SIR AUREL (1862-1943), British archaeologist, was born at Budapest on Nov 26, 1862. Educated at Budapest and Dresden and at the Universities of Vienna and Tubingen. he went to England for further study and then to India, where he became principal of the Oriental college, Lahore, and registrar of the Puniab university in 1888. He was appointed in 1800 to the Indian Education service, and for the next two years carried out archaeological explorations for the Indian government in Chinese Turkestan. In 1906-08 he made further explorations in central Asia and western China. From 1910 he was superintendent of the Indian Archaeological survey, and in 1913-16 carried out explorations in Iran and central Asia, described by him in The Geographical Journal (1916), He was created K.C.I.E in 1912. In 1926 he continued his explorations on the northwest frontier and identified the site of Aornus, thus correcting Abbott's view, and between 1926 and his death explored Iran, Iraq and Trans-Jordan. He died in Kabul, Afghanistan, Oct. 28, 1043

in 1788 the previous close relationship between them came to an end although their friendship was later renewed. Goethe's letters to Frau von Stein form one of the most interesting volumes of the poet's correspondence. She was also a close friend of Schiller and his wife, and numerous interesting letters from her are to be found in Charlotte von Schiller und shre Freunde (vol ii, 1862). She became a widow in 1793 and continued to live at Weimar until her death there on Jan 6, 1827

Gethe's Brief an Fron von Stem aus den Jahren 1776-1820 was clited by A. Scholl (3 vols), 1848-1851, and ed by W. Fabitt, 1883-1885, 3rd ed by J. Wallet, 1900. Set H. Duntter, Charloise von Stem (2 vols), 1874); al. Charloite von Stein und Corona Schroter (1879), ed. H. Ostert, Charloite von Stein (1800. and New York, 1877), and A. Saure, Framenbider aus den Blutesti der deutschen Literatur (1889). W. Bods, Charlotte von Stein (1900.)

STEIN, GERTRUDE (1874-1946), expatriate U S author, was born in Allegheny, Pa, Feb 3, 1874, spent her infancy in Vienna and Paris, her girlhood in Oakland, Calif. She read Shakespeare at eight years. At Radchffe college, 1893-97, she specialized in psychology. William James is said to have considered her the most brilliant woman pupil he ever had She studied at Johns Hopkins Medical school, 1897-1902. Of independent means, she went abroad to live in 1903. Her home in Paris, 27 rue de Fleinus, was a centre for artists and writers for more than a generation After 31 years, she returned to the U.S for a lecture tour in 1934 Notwithstanding her German-Jewish origin, she continued living in Paris under nazi occupation

A literary "cubist," Gertrude Stein carried to extremes her weird, repetitious, and seemingly nonsensical manipulation of words and of words and of words. "Widely ridiculed and seldom enjoyed," comments Edmund Wilson in a chapter about her in Axel's Castle, "she has yet played an important role in connection with other writers who have become popular" Sherwood Anderson and Ernest Hemingway were two such. In The Autobiography of Alsce B. Toklas (1933), simply written and easily readable, Miss Stein, while ostensibly writing the life of her secretary and close companion since 1907, actually wrote her own In this book she appeared as one of her protégés, Bravig Ihms, called her in his Confessions of Another Young Man, a "vital, headstrong and cordial personality," with "an insatiable appetite for people' They came and went in an unending procession, year after year, some famous, some unknown, some to become famous later. Matisse, Cézanne, Pablo Picasso, Juan Gris, Mildred Aldrich, Clive Bell, Wyndham Lewis, Carl Van Vechten, Avery Hopwood, Ezra Pound, Ford Madox Ford, Bernard Faÿ, André Gide, John Reed, Elhot Paul, Jo Davidson, Paul Robeson, and scores of others.

"Flowing," said Carl Van Vechten, "is the one word that best describes Gertrude Stem." Sherwood Anderson likened her to "an American woman of the old school," plain and strong, who worked hard in her "kitchen" to make good things-out of words She was a substantial person, with a striking head and close-cropped hair. She dressed plainly. She laughed infectiously. When angry, she swore Her favourite song was On the Trail of the Lonesome Pine. Alice Toklas, so the Autobiography recounts, knew personally three geniuses in her lifetime: Picasso, Alired North Whitehead and Gertrude Stein. She died on July 27, 1946, in Paris.

The principal works of Gertrude Stein are Three Lives (1908); Tender Buttons (1915); Geography and Plays (1923); The Mak-Tender Dittons (1915); Geography and ruys (1923); He making of Americans (1925); Useful Knowledge (1928); Acquaintance with Description (1920); Ten Portraits (1930); Lucy Church Amably (1930); Before the Flowers of Friendship Faded Friendship Faded (1931); How to Write (1931); Operas and Plays (1932); Matisse, Picasso and Gertrude Stein (1932); The Autobiography of Alice B. Toklas (1933), Four Saints in Three Acts; an opera (1934); Portraits and Prayers (1934); Lectures in America (1935); Narration (1936); Everybody's Autobiography (1937), Picasso (1938); The World is Round (1939); Paris France (1940); Ida (1941); Wars I Have Seen (1945); Yes Is for a Very Young Man; a play (1946); Brewsie and Willie

STEIN, HEINRICH FRIEDRICH KARL, BARON VOM UND ZUM (1757-1831), German statesman, was born at the family

estate near Nassau, on Oct. 26, 1757 He studied law at Gottingen, Wetzlar, Regensburg and Vienna, and settled in Berlin in 1780. There he entered the Prussian service.

After holding various diplomatic and other appointments he became (1787) Kammerdirektor, ie, director of the board of war and domains for the king's possessions west of the river Weser; and in 1796 he was appointed supreme president of all the Westphalian chambers dealing with the commerce and mines of those Prussian lands Among the benefits of his administration was the canalization of the river Ruhr, which became an important outlet for the coal of that region. He also improved the navigation of the Weser, and kept up well the main roads committed to his care On June 8, 1793 he married the countess Wilhelmine von Wallmoden-Gimborn, daughter of a natural son of King George II of Great Britain

Stein's early training, together with the sternly practical bent of his own nature, made him completely impervious to the enthusiasm which the French Revolution had aroused in many minds in Germany He disliked its methods as an interruption to the orderly development of peoples. Nevertheless he carefully noted the new sources of national strength which its reforms called forth in France Under the untoward circumstances which followed the Peace of Basel Stein in 1804 took office at Berlin as minister of state for trade. He protested against the effects of the Gallophil policy of the chief minister, Haugwitz, and the evil influences which clogged the administration. Little, however, came of Stem's protests, though they were urged with his usual incisiveness and energy Prussian policy continued to progress on the path which led to the disaster at Jena (Oct 14, 1806).

The king then offered to Stein the portfolio for foreign affairs, which he declined, because he desired to see Hardenberg take that office and effect, with his own help, the necessary administrative changes. The king refused to accept Hardenberg, and, greatly irritated by Stein's unusually outspoken letters, dismissed him altogether, adding that he was "a refractory, insolent, obstinate and disobedient official." Stem now spent in retirement the months during which Napoleon completed the ruin of Prussia; but he saw Hardenberg called to office in April 1807 and important reforms effected in the cabinet system. During the negotiations at Tilsit, Napoleon refused to act with Hardenberg, who thereupon retired Strange to say, the French emperor at that time suggested Stein as a possible successor, and on Oct. 4, 1807, Frederick William

called Stein to office with very wide powers

Stein's strong convictions led him to press on drastic reforms in a way which could not otherwise have been followed. First came the Edict of Emancipation, issued at Memel on Oct 9, 1807, which abolished the institution of serfdom throughout Prussia from Oct 8, 1810. All distinctions affecting the tenure of land (noble land, peasants' land, etc.) were also swept away, and the principle of free trade in land was established forthwith. The same famous edict also abrogated all class distinctions respecting occupations and callings of any and every kind, thus striking another blow at the caste system which had been so rigorous in Prussia. Stein's next step was to strengthen the cabinet by wise changes and he also furthered the progress of the military reorganization which is connected more especially with the name of Schamhorst (q,v). Stein's efforts were directed more towards civil affairs; and in this sphere he was able to issue a measure of municipal reform (Nov. 19, 1808) which granted local self-government on enlightened and practical lines to all Prussian towns

In August 1808 the French agents, who swarmed throughout the land, had seized one of his letters, in which he spoke of his hope that Germany would soon be ready for a national rising like that of Spain. On Sept. 10 Napoleon gave orders that Stein's property in the new kingdom of Westphalia should be confiscated, and he likewise put pressure on Frederick William to dismiss him. The king evaded compliance; but the French emperor, on entering Madrid in triumph, declared (December 16) le nommé Stein to be an enemy of France and the Confederation of the Rhine, and ordered the confiscation of all his property in the Confederation. Stein saw that his life was in danger and fled from Berlin (Jan. 5, 1809) to Bohemia.

For three years he lived in the Austrian empire, generally at Brunn, but in May 18:1 be received an nuvitation from the emperor Alexander I to visit St. Petersburg, seeing that Austrian was certain to range herself on the side of France in the forthcoming France-Russian War. At the crisis of that struggle Stein may have been one of the influences which kept the tast determined never to treat with Napoleon. When the miserable remains of the Grand Army reclied back into Piussia at the close of the year, Stein urged the Russian emperor to liberate Europe.

Events now brought Stein iapidly to the front On Dec. 30, 1812, the Prussian general Yorck signed at Tauroggen a convention with the Russian general Diebitsch for neutralization of the Prussian corps at and near Tilsit, and for the free passage of the Russians through that part of the king's dominions The tsar thereupon requested Stein to act as provisional administrator of the provinces of East and West Prussia. In that capacity he convened an assembly of representatives of the local estates, which Feb 5, 1813, ordered the establishment of a militia (Landwehr). a militia reserve and a final levy (Landsturm). He took part in the drafting of a Russo-Prussian convention (March 19, 1813) respecting the administration of the districts which should be delivered from French occupation. During the varying phases of the campaign of 1813 Stein continued to urge the need of war à outrance against Napoleon. The Allies conferred on Stein the important duties of superintending the administration of the liberated territories After the battle of Leipzig (Oct. 16-19, 1813) Stem entered the city

He now desired to see Germany reconstituted as a nation, in a union which should be at once strong for purposes of defense and founded on constitutional principles. His statesmanlike projects were foliale, partly by the short-sightedness of German rulers and statesmen, but also by the craft with which Metternich guined the allance of the rulers of south and central Germany for the Austrian empire. During the Congress of Vienna Stein pressed in van for an effective union of the German people. Austra and the secondary German states resisted all proposals in this direction, and Stein blanded the Prussian chancellor Hardenberg for an indefiniteness of purpose which probably resulted from the decisie of all Presson statemens at that time to have Saxony wholly absorbed in their kingdom. In that, as in other matters, he was disappointed.

Stem passed into retirement after the Congress of Vienna, and as we that and disgust the postponement of the representative system of government which Prederick William had promised to Prussa in May 1812. His chief interest was in the sixed of listory, and in 1818-1820 he worked hard to establish the society for the encouragement of historical research and the publication of the Monumenta Germaniae Instorica, of which his biggrapher, Perts, became director. Stein died on June 29, 1831.

Possibly there has been a tendency to magnify the achievements of Stein. Research has shown that the credit for originating his reforms must be shared with Heinrich Theodor von Schon and many others. The king hmself rendered large services to this manual than the stein should be supported to the control of the stein should be supported to the stein should be supported by the stein should be su

human energy ensured the triumph of these principles.

STEINER, JAKOB (1796–1863), Swiss mathematician, was born on March 13, 1796, at the village of Ulcendorf (Berne). At egipteen he became a pupil of Helmich Pestalozar, and afterwards studied at Heidelberg Thence he went to Berlin and became one of the chief contributors to Crelle's Journal founded in 1846 in 1844 a new chair of geometry was founded for him This he occupied till his death on April 1, 1863.

Steiner was one of the great developers of synthetic geometry. In his Systematische Entwickelung der Abhangigkeit geometrischer Gestalden von emmander he introduces the geometrical forms (the row, flat pencil, etc.), and establishes between their elements a one-one correspondence, or, as he calls it, makes them projective Sec C. F. Geiser's pamphlet, Zur Ernnerung an J. Steiner (Zurich, 1874).

STEINER, RUDOLF (1861-1925), German philosopher, was born on Feb. 27, 1861, at Kraljevic, Austria, the son of a minor railway employee, From 1890 to 1897 he worked in Weimar at the "Goethe-Schiller Archive," editing Goethe's works on natural history. In 1902 the German section of the theosophic association was founded and Stemer was called upon to become its spiritual leader. As such he developed for some years an astonishing activity as regards lectures and writings, but then became opposed to theosophy altogether, and was therefore excluded from the theosophical centre under English leadership. Steiner now developed his own teaching in a series of writings He called this "anthroposophy," : e , wisdom of humanity mankind is regarded as the centre of all perceptions of this "spiritual science," and an attempt is made to deduce the nature of the world from the nature of humanity. In 1913 the Anthroposophical society was formed to further spiritual research on Steiner's principles. In order to try his educational and political views in practice, Steiner founded the Waldorf school, near Stuttgart, and the "free high school for spiritual science" known as the "Goetheanum" at Dornach near Basle, which was burned a few years later All Steiner's works are published by the Philosophisch-anthroposophischer-Verlag, Berlin, and Der kommende Tag, Stuttgart. He died at Dornach on

March 30, 1925. His chief works include Goethe, als Vater einer neuen Aesthetik (1888), Eng ed. in preparation; Die Philosophie der Freiheit (1894), Eng trans. ed. H Collinson, The Philosophy of Freedom (1916); Friedrich Nietzsche (1895); Goethes Weltanschauung 1897), Theosophie (1904), Eng. trans by E D. STEINLE, EDUARD (1810-1886), Austrian painter, was born in Vienna on July 2, 1870. In 1838 he joined the "Nauarene" groups, started by Overbeck and Cornelius in Rome. It was not, however, a congenial atmosphere for one of his romantic temperament, and in 1833 he returned to Vienna, moying in 1838 to Frankfurt, where he was professor of historical painting at the

Steiner (1922).

iPhus Schön's memorandum on the aboliton of serdom was the basis of the law of emanicaption; and Stein's Politisehes Testamen, was also based on a draft by Schon. Schon was born in 1773, which is the state of the state of the state of the state of the virtual high ministerial appointment. Plays and attacked with \$750, and an extra of the state of the state of the state of \$751, of Marsenburg on his retirement in \$452, and died in \$850. The share claimed by him in Schur's reforms has been the subject of

Staedel institute from 1850, and where he died on Sept. 19, 1886. He had the freshness and poetical fancy of the Viennese, and his best work is found in such legendary subjects as "Loreley" (Shack gallery, Munich), "The Violinist," and the illustrations to fairytales by Brentano and others.

STEINMETZ, CHARLES PROTEUS (1865-1923). American electrical engineer, born at Bieslau, Germany, April 9, 1865 He was educated at Breslau, Zurich and Berlin, specializing in mathematics, electrical engineering and chemistry. His activities as a Socialist led him into difficulties with the authorities, and, after a short sojourn in other countries, he emigrated in 1880 to the United States and found work with the Osterheid and Eickemeyer factory at Yonkers. In 1893 when that factory was absorbed by the General Electric Co., Schenectady, he was given an appointment as consulting engineer. His knowledge won him speedy promotion and he soon became recognized as one of the outstanding electrical geniuses of America. After 1902 he served also as professor of electrical engineering at Union college. Stemmetz regarded his three greatest contributions to electrical science to be. (1) his investigations on magnetism resulting in his discovery of the law of hysteresis, which enabled losses of electric power due to magnetism to be accurately forecast before starting the construction of motors, generators, transformers, and other electrical apparatus employing iron; (2) the development of his symbolic method of calculating alternating-current phenomena which simplified an extremely complicated field, understood by few, so that the average engineer could work with alternatingcurrent, an accomplishment which was largely responsible for the rapid progress made in the commercial introduction of alternatingcurrent apparatus, (3) his investigation of lightning phenomena which resulted in his theory of electrical transients, and opened the way for his development of lightning arresters to protect highpower transmission lines Though primarily a mathematical genius and a student of theory, he had some 200 patents to his credit. including improvements on generators, motors, transformers, in electro-chemical operations, and the invention of the induction regulator, the method of phase transformation and the metallic electrode arc lamp. Besides a large number of scientific papers he was the author of a number of standard text-books. He died at Schenectady, N.Y., Oct. 26, 1923.

See J W Hammond, Charles Proteus Steinmetz, a Biography (1924), and J. N. Leonard, "Steinmetz, Jove of Science," in World's Work, vol. 53, nos 2, 3 and 4 (1929).

STEINMETZ, KARL FRIEDRICH VON (1796-1877), Prussian general field-marshal, was born at Eisenach on Dec 27, 1796 At the outbreak of the War of Liberation he and his elder brother made their way through the French posts to Breslau, where they at once received commissions The biothers took part in the hardest fighting of the campaign of 1813, the elder being killed at Leipzig and the younger being more than once wounded. After the peace he entered Paris but once, fearing to infringe upon the ten ducats that he saved monthly from his pay to send to his mother. His character and physique were strengthened by his Spartan way of life, but his temper suffered. From 1820 to 1824 he studied at the General War academy.

Steinmetz was promoted general of infantry in 1864, and led the V Corps to the war against Austria in 1866. This was the chance of his lifetime. His skilful and resolute leadership was displayed in his three battles, won on three successive days, of Nachod, Skalitz and Schweinschädel (see Seven Weeks' WAR)

At the outbreak of the war of 1870 Steinmetz was appointed to command one of the three armies assembled on the Rhine, the others being led by Prince Frederick Charles and the crown prince. Serious differences arose between Steinmetz and Prince Frederick Charles. After the battle of Gravelotte he was relieved of the command of the I Army and was sent home as governorgeneral of the V and VI Army Corps districts. In April 1871 he was retired at his own request, but his great services were not forgotten, and he was promoted to general field-marshal. He died at Bad Landeck on Aug. 2, 1877.

STELE, a nonstructural pillar or vertical slab of stone, metal or marble, usually set up for votive or commemorative purposes, sometimes decorated with bas-reliefs and bearing inscriptions, and generally terminated with a cresting enriched in classic examples with the anthemion plant with a small pediment. Stelae are common in Chinese tombs and temples, and usually these consist of an inscribed panel crowned by the dragon, and supported

on the back of a great turtle STELLAR CONSTITUTION AND EVOLUTION. Mere observation of the stars cannot tell us which are young and which are old, for all their changes are far too slow to detect. The only safe guide is a physical theory, which starts from knowledge of the general properties of matter and deduces the behaviour of great masses isolated in space through long intervals of time. Such knowledge first became available with the advance of atomic physics shortly after 1920 By 1945 the general constitution of the stars appeared to be fairly well understood-though only a beginning can be made toward deducing their history throughout the ages

Constitution of the Stars .-- An isolated mass of matter will settle down into a spherical form unless it is distorted by rotation (a complication which need not be considered in this sketch). The gravitational attraction of the body will produce a pressure, increasing toward the centre, which may be calculated for any assumed "model" defining the increase of density toward the centre The temperature at any point follows from the pressure and density, if the composition of the material is known, and the familiar gas laws may be assumed.

For bodies comparable in size and mass with the stars, the calculated temperatures come out in millions of degrees.

The properties of matter under these conditions are now fully understood, and are considerably simpler than at ordinary temperatures. All substances are volatilized, all compounds decomposed, and all but a few of the innermost electrons are stripped from the nuclei of the atoms. The simple gas laws may safely be applied unless the density exceeds a thousand times that of water The calculated temperature for a given pressure and density depends very little upon the composition, except that the presence of hydrogen lowers it considerably, and of helium to a smaller degree. At the centre of a body of the size and mass of the sun, the temperature is of the order of 20,000,000° C .-- varying with the density model and hydrogen abundance. At corresponding points in stars of the same composition, and built on the same model, the temperature is directly proportional to the mass, and inversely to the radius (Lane's law)

This theory is due mainly to Sir Arthur Stanley Eddington, who applied it with marked success to the study of the escape of heat from a star.

Stellar Luminosity.- Inside a star radiation is flying from atom to atom in all directions but going only a short distance before it is absorbed and re-emitted. On the average this results in a flow of energy from the hotter to the cooler parts, at a rate which is greater the more rapid the fall in temperature per mile; and less, the greater the opacity of the gas to radiation. The laws which govern the emission and absorption of radiation in a very hot gas are now well established, and the rate of escape of heat from the interior to the surface of a star can be calculated. The surface will automatically adjust its temperature so that it loses into space as much as it receives from below, so that this calculation gives us the total heat radiation, or luminosity, of the star

It is found (again following Eddington) that the luminosity of a star depends primarily upon its mass-increasing somewhat faster than the cube of the latter. This conclusion is fully confirmed by observations of hundreds of stars, which afford strong evidence of the essential soundness of the theory and the postulates on which it is based.

Changes in the size of a star have but a small effect on its calculated luminosity, which varies inversely as the square root of the radius.

The effect of changes in the density model is rather small-

rarely exceeding a factor of three Stars containing no hydrogen should be much brighter (in some cases root times) than those containing 50% hydrogen. (For stars composed almost entirely of hydrogen, the calculated brightness increases again: but no such cases appear to be known) A body of the sun's size and mass would shine as brightly as the sun if it contained 35% by weight of hydrogen, no helumn and 65% of heavier atoms; also with 31% hydrogen, 42% helum and 7% heavy atoms; and for a series of intermediate compositions.

The Contraction Theory .- The energy which a star radiates must be provided from some internal source. Before the rise of atomic physics, the greatest known supply was the gravitational potential energy, arising from the mutual attraction of its parts. These attractive forces tend to compress the star If they were not balanced by the internal pressure of the gases of the interior the star would contract, the gravitational forces would do work. and a corresponding amount of potential energy would be liberated, appearing as heat of compression in the gas. If, at a given instant, the internal pressures just balanced those due to gravity, nevertheless, as the star lost heat by radiation from its surface. the interior would tend to cool and the gas pressure to diminish Contraction would then begin and continue till enough heat had been produced to raise the pressure and restore the balance. The evolution of a star, on this conception, would be a gradual shrinkage-part of the heat liberated by transformation of the gravitational potential energy maintaining the internal equilibrium and the rest keeping up the radiation.

This first rational theory of stellar evolution owes its origin to Herman won Helmholtz. What proportion of the liberated energy is stored inside the star, and how much remains available to keep it shinning, can be calculated from the known laws of gases. Much of the internal energy is the kinetic energy of motion of the atoms of the gas, to which it owes its high temperature. Part is energy of iomization. The collisions between the atoms are so violent that the outer electrons which normally belong to their structure are detached and fly about independently. To remove them against the electrical attraction of the residue of the atoms demands a large expenditure of energy which would be released again if the gas should cool and the collisions become less violent. Finally, the radiation imprisoned within the star, flying from atom to atom and gradually working it way out to the surface, carries an amount of energy which, especially in the stars of greatest mass, is a considerable fraction of the whole.

All told, it appears that more than half of the energy liberated by contraction, and sometimes a good deal more, must be stored inside the star in these three forms; but that, under actual conditions, a surplus will be available to meet the loss by radiation.

Age of a Star—When the length of a star's life comes to be considered, the contraction theory meets with grave difficulties. The amount of gravitational energy which would have been re-leased by the contraction of the sun, for example, from an indefinitely great size to its present dimensions is readily calculable, and is found to amount to as much as would supply the present rate of radiation from the surface for 46,000,000 years. More than half this must still be stored inside the sun, and 20,000,000 years' supply at most can be counted available for radiation. This was sointed out long are by Lord Kelvin.

But there is now abundant evidence from radioactive data that the oldest sedimentary rocks recognized by geologists are more than 1,000,000,000 years old (probably somewhat more), and that, during all this interval, the temperature of the earth's surface has been closely the same as at present. The sun has therefore, during geological time, dissipated in radiation more than 50 times as much energy, as it could have derived from gravitational sources, and yet has remained of about the same brightness all the time. For the giant red stars of low density the case is even stronger. The gravitational energy available for a star's even stronger. The gravitational energy available for a star's upon the star of the sun, and 40 probably only 30 or 40 primes as great, as for the sun, and 40 probably only 30 or 40 primes are to a star of the sun, and 40 probably only 30 or 40 primes are to a star of the sun, and 41 to 2000 time the sun's rate, so

that its whole past history, if gravitational energy only were available, would occupy only 6,000 years.

Subatomic Energy—Such arguments have convanced practically all workers in the field that the sun, and the stars in general, must draw to maintain their radiation upon some vast supply of energy whose very existence was previously unsuspected. The only storchouses in the known universe small enough to hold so much energy are the tiny nuclei of the atoms, or perhaps the still smaller protons and electrons of which they are composed. For particles at greater distances, such as those at the periphery of an atom, the forces are not great enough to do so much work. The main source of stellar energy appears therefore to be of "sub-stonic" nature.

Loss of Mass .-- A second conclusion follows from the theory of relativity. According to this all energy possesses mass, and mass and energy are, to some degree at least, interconvertible, in a definitely known ratio. To m grams of matter correspond mc2 ergs of energy (where c is the velocity of light). Translated into more familiar units, this means that it is as legitimate to speak of a pound of heat as of a pound of iron. But a pound of heat is a very large amount, measured by ordinary standards; it would suffice to raise 20,000,000 tons of rock to a temperature of 1,500° C. and melt it into incandescent lava. The amounts of heat involved in all ordinary thermal changes are therefore of such small mass that it is still usually permissible to treat heat as "imponderable", but when it comes to the radiation of the stars the case is different. The sun radiates energy into space at the rate of 3.8×1033 ergs per second—a number too great to be directly appreciable even by the physicist. Expressed as mass, this means that the sun is getting rid of 4,200,000 tons of heat every second No other mode of statement comes so near to conveying to human apprehension the tremendous activity of a star.

The sun's mass must actually be diminishing at this portentous rate, which might raise fears of its disappearance. But its present mass is so great (\* 198\cdot 100 argams) that the existing radiation would use up only a millionth part of it in 7,5000,000 years, and the consumption of a moderate fraction would give a life long enough to meet the wildest demands of geology.

The process of transformation by which mass disappears and energy is hierated within the stars must satisfy these conditions.

(1) it must be a nuclear reaction; (2) it must be capable of furnishing energy at the observed rate (usually a few ergs per gram per second) in the stellar gas at a temperature of the order of 20,000,000° C; (3) it must be self-regulars, so that stars of different masses can have different rates of supply, and stable—free from danger of catastrophe. The last requirement may be considered first, since it depends upon the properties of a star as a whole.

Stability—The rate at which heat can escape from a star changes but little with its size. If, in a given configuration, the rate of income of heat from subatomic sources is less than the rate of escape, the star will have to draw on its gravitational store, and contract; if the income exceeds the outgo, the process will be reversed, and the star will expand, storing up the excess energy by means of the work done against gravitation.

As a star contracts, the rate of expenditure of heat by radiation from its surface will slowly increase, and the temperature and pressure in its interior will also rise. If these changes increase the rate of liberation of subatomic energy fast enough, a star of deficient income, as it contracts, will find its income gaining upon expenditure, and will approach a state of equilibrium. Should it overshoot this and contract too far, the income would exceed the outge, and expansion would be forced, tending agant to restore equilibrium. In this case the equilibrium is stable; but if, after contraction, the outge gained upon the income, it would be unstable, and even a small unbalance would tend to increase indefinitely.

Eddington has pointed out that if this increase is too rapid the star will tend to pulsate (alternately expanding and contracting) to an increasing extent; but Cowling has shown that this pulsatory instability will not arise unless the rate of liberation of energy increases faster than the 20th power of the temperature, so that the margin of safety is wide

Nuclear Reactions,-Further progress depends upon a knowledge of actual reactions between nuclei Fortunately, it is possible, with the aid of the cyclotion and similar devices, to accelerate nuclei of hydrogen (protons), of deuterium (deuterons) and of helium (alpha particles) so that their collisions with other atoms are extremely violent, and a great variety of nuclear reactions, involving practically all the elements, have been observed In many of these, changes in the total mass of the reacting partycles occur; with corresponding liberation of energy; but these all involve transformations in which but a small fraction of the whole mass disappears. Annihilation, with the complete disappearance of the particles and liberation of all the corresponding energy, has been observed for positive and negative electrons, but never for particles of greater mass. It is to transformation, therefore, and not to annihilation of atoms, that the source of stellar energy is to be ascribed.

For example, the mass of a hydrogen atom is 1 co813 of the chemist's ordinary untst, and that of a helum atom 4 co386 A process, or set of processes, which resulted in the transformation of four hydrogen atoms into a helum atom would diminish the mass by 1/41 of the original amount. To liberate the 4,200,000 tons of energy which the sun radiates every second would require the transformation of \$90,000,000 tons of hydrogen not helum every second. At this rate, the hydrogen which is present in the sun would last for at least \$5,000,000,000 years.

Reactions between protons and many heaver nuclei have been studied in the laboratory. The helium nucleus alone is inert—too studied in the laboratory. The helium nucleus alone is inert—too stable to disturb For the others, the probability of a successful hit by a proton of given energy can be measured, and from this it is possible to calculate how rapidly each reaction would occur in a hot dense gas containing given proportions of hydrogen and the atoms concerned.

The most valuable nucleus is the deuteron (heavy hydrogen) which, in a body of the sun's mass would supply heat enough to supply the sun's radiation at a gas temperature of about 4,000,00° C. Lithium, the next lightest element, would be affected at about 2,000,00° C; and born and beryllimar at from 4,000,00° to 9,000,00° for different isotopes. In all these cases the reaction products break down, either at once or after a few intermediate stages, into helium nuclei, and no trace is left of the nuclei which originally reaction.

The Carbon Cycle.—Carbon behaves quite differently—taking part in a very remarkable cycle of reactions, discovered by Hans A. Bethe, which are so important that it is worth while writing down the equations which express them.

$$\begin{array}{cccccc} C^{12} + H = N^{13} + \gamma & N^{14} + H = O^{15} + \gamma \\ N^{13} & = C^{12} + e^{+} & O^{15} & = N^{15} + e^{+} \\ C^{15} + H = N^{14} + \gamma & N^{15} + H = C^{12} + H e^{4} \end{array}$$

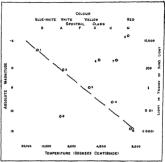

A proton H, entering an ordinary carbon nucleus C<sup>18</sup> (of mass 12), forms a pecultar kind of nitrogen N<sup>19</sup>, while excess energy is liberated as a gamma-ray, 7. This nucleus is radioactive, and breaks down in a few minutes, emitting a positive electron e, and turning into the heavier isotope of carbon C<sup>19</sup>. Two more proton penetrations follow, producing first ordinary nitrogen N<sup>18</sup>, and then a radioactive oxygen, O<sup>19</sup>, which decays into the rare isotope of nitrogen N<sup>19</sup>. When a proton hist his nucleus, He combined mass breaks up into two pieces, a helium nucleus, He<sup>4</sup>, and one of carbon like the ordinari one. Every one of these six reactions has been produced and studied in the laboratory, and there is no guesswork at any point. Energy is liberated at each step as radiation or by rapidly moving particles—and is speedily transformed to heat in the gas.

The distinctive feature of this process is that the carbon is regenerated ready to work again. The lighter nuclei play their part in consuming hydrogen but are consumed themselves at the same time, while carbon and its associated nitrogen work again and again and can catalyze the transformation of many times their own weight of bydrogen without being exhausted.

In a star like the sun, this cycle would furnish the needful energy supply at a temperature of about 20,000,000° C. (depend-

ing on the amounts of carbon and of hydrogen). For example, in the model already described, containing 31% of hydrogen, the presence of 3% carbon and ntrogen together would be sufficient It is now generally agreed that this is the process by which the sun's radiation is actually mantained.

Reactions between protons and heavier nuclei, such as oxygen and fluorine, are known, but they demand a higher temperature,

RELATIONS BETWEEN THE COLOUR AND BRIGHTNESS OF STARS
RELATIONS BETWEEN THE COLOUR AND BRIGHTNESS OF STARS
STARS OF OFFICE AND STARS OF STARS

and so would not have a chance to occur in a star containing carbon or nitrogen, which would get rid of its hydrogen before they came into play. Another process involving formation of deuterons by collision of two protons, and ultimately converting hydrogen with helium, is theoretically possible, and may occur in some stars of high density and low temperature, but its rate cannot yet be calculated with any accuracy.

Theoretical History of a Star.—We may now sketch a scheme of stellar evolution, based entrely on the known properties of atoms. Start with a large mass of low density, containing atoms of all sorts. It will come rapidly into a spherical form, under its own gravitation. If its mass is as much as roopool times that of the earth, it will be very hot inside, and enough heat will escape to the surface to keep this incandescent. It will be a star.

So long as the central temperature is low, no nuclear energy will be liberated and the star will draw on its gravitational energy and contract. With rising internal temperature, the reactions involving the lighter nuclei will successively be "unmer don." Contraction will practically cease when enough heat is liberated from the nuclear process—to be gradually resumed as the active constituent becomes exhausted. In this way all the light nuclei will be consumed in successive or overlapping stages until the carbon cycle comes into play. If, as seens probable, hydrogen was originally very abundant, there will be a prolonged halt in contraction, while the hydrogen tiself is being consumed.

So much is clear; but further details depend upon a question which has not yet been theoretically settled. If the gases inside the star are kept mixed by currents, turbulence, or the like, practically all the hydrogen will in time be transported to the hot centre and consumed. But, if there is little or no mixing of concentric layers, a core of eshausted material (helium and heavy nucle) will form, surrounded by a working layer in which nuclear reactions are occurring and this again by an outer part too cool to permit them. The theory of this model is complicated, and by 1945 had not been fully worked out.

Lithium, berylhum and boson are present in the sun's atmosphere, though m very small quantities, and must long ago have been completely consumed in its interior. Hence mixing has not been complete, but it may have been extensive

Assuming thorough manag, which is theoretically easier to work with the temperature made our hypothetical star would tend to rise as the percentage of hydrogen dimmished. Its radiation would also increase, and calculation shows that a slight increase of diameter would at first be required to prevent too great a liberation of energy. Finally, when the hydrogen was almost exhausted, contraction would begin. With the bydrogen gone, contraction would have to supply almost all the radiation, since the reactions which might happen between heaver nuclei at high temperatures would liberate relatively little energy.

Limiting Density .- The question whether any limit would be set by nature to such a contraction can be answered only by an appeal to fundamental principles of quantum physics. Sir Ralph Fowler showed in 1926 that such a limit would exist. There is a fundamental "exclusion principle" which prohibits the occurrence of any two electrons within an atom which are in exactly the same state, and accounts for the ground plan in which atoms are built, and on which their physical and chemical properties depend. Applied to a mass of gas, this same principle fixes a limit to the number of slowly moving particles which can occupy any given volume of space-say a cubic centimetre. Where this limit is reached, only faster moving particles can get in, and to crowd more and more of them into the same space requires an everincreasing pressure. So long as all the particles are shut up in this volume, their motions will not slow down below the average value set by this principle. Additional energy, if supplied to them, would set them moving faster, and increase the pressure. This excess could escape again as heat, but the "zero-point energy" cannot so escape, nor the corresponding pressure be reduced

In a mass of ionized gas, the electrons, which are the fastes moving particles, would be the first to suffer from this restriction, and become degenerate. The properties of a degenerate gas can be precisely calculated and then those of a body composed of it. It is found that a mass equal to the sum's and containing no hydrogen would, if completely degenerate, have a diameter of about 13,000 mm, and a mean density somewhat more than 1,000,000 times that of water.

In this condition, it would have lost all the heat which it might have contaned when larger and all that which would be liberated by contraction, except for the irremovable zero-point energy, and could contract no further. At the limit it would be cold and other, and "fixed in an eternal state" apart from the chance of collision with another body. A very this surface layer would still consist of ordunary nondegenerate matter, but would form a negligible fraction of the whole body.

For smaller masses, the calculated limiting diameter is larger, and the limiting density smaller. For larger masses the calculated velocities of the electrons approach those of light, and relativistic theory must be applied. S. Chadrasekhar, after a thorough study, has concluded that for masses more than 1.5 times the sum's, and containing no hydrogen, the velocity which the electrons must have to support their share of the gravitational pressure will ach ways be greater than the zero-point velocity, so that the gas an never become completely degenerate, and no limit can be set to its contraction.

Present theory, therefore, presents this picture of the later history of a star. After the hydrogen has been enhanted by the carbon cycle, the body contracts, growing very much hotter finish and considerably hotter on the surface, and increasing in humonsity. This stage probably occupies but a small portion of the star's history. For smaller masses, maximum internal and external temperatures will be reached at a diameter probably about five times the limit just discussed. After this the star cools and grows fainter, still shrinking slowly until it settles down toward the dense degenerate state and, at long last, becomes an inert dark body. Stars of larger mass continue to contract beyond the power of present theory to follow them.

It should be especially notized that this long account has been derived entirely from general physical theory. No use has been made of actual observations of the stars except to define in a general way the masses, sizes, and composition of the type of bodies with which we are dealing, and to calculate illustrative examples for a body comparable with the sun (except for a few incidental notes, unimportant to the course of the argument)

notes, manipora with Observation—a significant, these predictions with the actual properties of the stars, some stream the stead properties of the stars, some stream the steady test those which can be found by observation for large numbers of them. The most studable characteristics are the luminosity (of the absolute magnitude, which is another way of describing the same things) and the surface temperature (for which the colour of the light or the type of spectrum may be substituted), since all these are very closely correlated

Plotting the absolute magnitude vertically and the spectral type horizontally, diagrams have been prepared showing the relations for thousands of stars. It is found that the points on the diagram

are very far from being distributed at random.

The Man Sequence.—The majority of the points are concentrated into a rather narrow band, running downward to the right across the diagram, as illustrated schematically by the heavy broken line in the figure. The corresponding stars form a great group called the mans sequence, including all colours and all degrees of brightness, but with all the faint stars red, all those of medium brightness yellow (the sun belongs here) and all the bright ones white. The extreme range of brightness is much more than a millionfold. That in the diameters (which may be readily calculated) is thirty or fortyfold, and in the masses a hundredfold (agreeing with Eddington's relation)

With the density model indicated by the laws of radiative equilibrium, the central temperature comes out about 25,000,000° C for the sun, 35,000,000° or 40,000,000° for the great white stars at the top of the sequence, and 75,000,000° or 20,000,000° for the faint red ones at the bottom. There must be a reason for this similarity.

It has already been mentioned that Bethe's carbon cycle suffices to account for the source of the sur's energy. When smillsr calculations are made, it is found that it will account for all the main sequence stars—the higher naternal temperatures in the hotter stars being just enough higher to provide the much greater amounts of energy per nut mass which they radate. The agreement is so striking that it is now generally agreed that the main sequence consists of stars whose energy is supplied by the operation of the carbon cycle. If all these stars contained exactly the same percontages of hydrogen and carbon, the points representing them perconages of hydrogen and carbon, the points expressing them if the percentages were different, the points specified in the carbon contained and the contained that the stars of the diagram, such as the star of the star of the contained that the stars contained exact the same cach also of this line, and form a strip extending diagonally across the diagram, as they actually do, even after allowance for the effect of errors in the observed data.

The existence of this great sequence of luminaries could have been predicted, and the place which the points representing them have on the diagram pretty closely defined, by applying general principles of physics, without ever having seen a star.

The White Duaris.—The point numbered 9 in the figure represents a star of a very different soit—the fails companion of the bright star Strius (which itself belongs to the main sequence). This star, though less than 1/300 as bright as the sun, is much hotter on the surface, and its diameter has been estimated as 1/30 of the sun's. Its mass is very nearly equal to the sun's, and its calculated men density 173,000 times that of water When these values were first calculated, they appeared unbelievable, but they are just what might be expected for a star which was almost completely in the degenerate state, though enough energy above the zero point still remained to keep it shining feebly.

About 40 "white dwarf" stars of this sort are now known. They differ considerably among themselves in brightness and colour, as is again to be anticipated theoretically. Such stars must be very numerous in space, but they are so faint that we can detect only the nearer ones.

The Giants and Super-Giants .- Many of the stars most con-

and are of high luminosity These bodies are of large diameterthat their masses agree fairly well with Eddington's relation

Their internal densities must then be very low, and their temperatures probably only a few milhon degrees, even at the centre. This is much too low to "turn on" the carbon cycle, but high enough to activate nuclear reactions involving the light elements.

the diagram by groups of points lying along several lines above the main sequence but parallel to it, and corresponding to reactions involving different elements. The points actually congregate in a rather wide strip extending upward to the right, as indicated by points 6, 7 and 8 in the figure. There are also "super-giants of very high luminosity, among which all varieties of colour and spectral type may be found.

At the time of writing (1945) the physical processes which supply these stars with energy were not fully understood. It could hardly be expected that the whole problem of the inner economy the physical field

the physics of the stars, the problem of their evolution remains full of difficulties. The chief complication arises from the very

The sun, according to the best present estimate of its composition, has reserves of hydrogen sufficient to keep it shining at its present rate for more than 30,000,000,000 years in the future, and helium enough to have required almost as long to accumulate. For a faint red star of the main sequence, the calculated life would be 15 or 20 times as long. Now there is much concordant evidence from different sources-ranging from radioactive production of lead in terrestrial minerals to the recession of the universe has been in its existing state for not more than 3,000,occ.coc years.

have passed through only a very small fraction of their whole career. If the white dwarfs have passed through earlier stages of normal density (as sketched above) their whole careers should have been even longer.

The stars of great luminosity, however, are spendthrifts. For example, each component of the eclipsing pair Y Cygni (at the very top of the mam sequence) has 17 times the sun's mass and about 30,000 times the sun's luminosity. The transformation of its whole mass from hydrogen into helium would keep it shinsuper-giants in general, the situation is similar, though not so acute.

The chief difficulties of a theory of stellar evolution, therefore, appear to be to explain why there are any super-giants still and any white dwarfs yet.

The most promising suggestion in the first case comes from work by L. Spitzer and F. L. Whipple, who have independently shown that dust and other small bodies, situated in a rotating system like the Galaxy, would tend to accumulate close to its equatorial plane. It is conceivable, though far from being proved, that such matter might have concentrated into great masses, and so started huge stars upon their lives as luminaries, at a relatively recent date in cosmic history-in which case those stars-as stars -are really young. No process for accelerating the development of a white dwarf has yet even been suggested, and we are left to the belief that they-and the faint stars in general-have been very much as they are now back to the remotest time to which we dare at present to extrapolate the past history of the universe (H. N. R.)

# STELLAR DISTRIBUTION: See STAR.

STELLENBOSCH, a town 31 mi. E. of Capetown by rail, and, next to the latter, the oldest town in the province; 33° 54' S., 18° 48' E.; altitude 364 feet. It was founded in 1681, and

spicuous to the eye are yellow and red, but lie at great distances named after the governor, Simon van der Stel, and his wife, whose maiden name was Bosch. The town is built in a valley, and its a few of them as big as the earth's orbit—but there is evidence streets are lined with oak trees and open channels of water Many of the houses with heavy, thatched gables date from the 17th century The Dutch church in the market square is also thatched. Stellenbosch is the centre of a rich fruit and wine producing area, and the headquarters of the Cape branch of the Dutch Reformed church, with a Dutch theological seminary There are several high schools in the town, a normal training If this were the whole story, we should find them represented on college and a self-contained university, in which the study of the Afrikaans language and literature 1s emphasized. The population in 1936 was 8,782, of whom 4,995 were Europeans, 3,558 "coloured," 52 Asiatics and 177 Bantu natives

STEM, in popular language the stalk of a plant or trunk of a tree. In botany a stem may be defined as an axis bearing leaves The stem with its leaves is known as the shoot. Structurally it differs from a root in having no cap (rootcap) over the growing point, in terminating in a bud and in having nodes and internodes. Even when the stem has a superficial resemblance to a root, as in some subterranean forms, it can be distinguished from one on of the stars should be solved at one blow by the first advances in the basis of its internal structure. The chief difference is the spatial relationship of the primary vascular tissues (xylem and Stellar Evolution.-With all this advance in knowledge of phloem) which is usually collateral or bicollateral in stems of gymnosperms and angiosperms and radial in roots. There are also differences in the manner in which the primary xylem is different rates at which stars of different masses should lead their differentiated in the two organs (e g, mesarch or endarch in many lives. Anatomy of Plants ) In general, the habit of the stern is erect or ascending, but it may lie prostrate on the ground, thus becoming procumbent as in the sweet potato and strawberry The scandent stem may climb on rocks or plants by means of rootlets as in wy; other vines have twining stems which twist around a supporting plant in a spiral manner like morning glory Twining plants turn either anticlockwise, as in Convolvulus, dodder and gourd, or clockwise, as in honeysuckle, twining polygonum and hop. In extra-galactic nebulae-which indicates strongly that the stellar other cases climbing plants are supported by tendrils which may be specialized stems as in the grape and passion flower, tendrillike leafstalks, as in clematis, or specialized leaflets, as in the pea During this interval, stars of small mass and luminosity should In warm climates twining plants (lianas) often form thick woody stems, while in temperate regions they are generally herbaceous In some plants the stem does not clongate during its early development but forms a short conical structure from which a crown of leaves arises These may form a bulb (onion, lily), a head (cabbage, lettuce) or a rosette as in dandelion and plantain Later this type of stem may grow rapidly into an elongated axis Subterranean stems include rhizomes, corms and tubers. These are described in a later section.

The character of the stem may be related to the longevity of ing at its present rate for only about 60,000,000 years. For the the plant, Thus many herbaceous plants or herbs are annuals and complete their life cycle in one growing season, after which the entire plant dies. In biemual herbs the whole plant dies after two years, the lower part of the stem or crown persists after the first growing season and bears buds from which an erect stem arises the second season. In perennial herbs the short crown stem may produce new shoots for many years. Plants producing permanent woody stems are called trees and shrubs. The latter produce branches from or near the ground, while the former have conspic-

uous trunks. Shrubby plants of small stature are called undershrubs or bushes. The limits between these different kinds of stem are not always well defined; and there are some plants occupying an intermediate position between shrubs and trees, sometimes called arborescent shrubs.

TESTA OR SEED COAT EMPRYO TWO FLESHY COTYLEDONS OR SEED LEAVES

FIG. 1-EMBRYO OF BEAN WITH COTYLEDONS SEPARATED

The stem is not always conspicuous. Plants with a distinct stem are caulescent; those in which it is inconspicuous are acaulescent, as the primrose, cowslip and dandelion. A similar term is given in ordinary language to plants whose stems are buried in the soil such as cyclamen and Primula Some plants are truly stemless. These may be

STEM 380

thallophytes or bryophytes (See ALGAE: FUNGI )

Development of Stem .- The first rudiment of the young shoot of the embryo appears from the seed after the radicle (young root) has protruded It is termed the plumule, and differs from the radicle in the absence of a rootcap and in its tendency to

ascend. (See SEED.) The apical growing portion constitutes the terminal bad of the plant, and by continued development the stem increases in height; projections appear at intervals, which are the rudimentary leaves. Lateral buds are produced which develop into lateral shoots more or less resembling the parent stem, and by these the branching of the plant is determined A bud may be found in the axil of a previously

in the angle formed between the

formed leaf; or, in other words, Fig. 2 -APEX OF SHOOT OF PHAN-EROGAMIC PLANT STEM

stem and leaf. Such buds are called axillary and are produced like the leaves from the tissues of the stem. During their development vascular bundles are formed which are continuous with those of the stem Ultimately branches are produced that in every respect resemble the axis from which the bud was differentiated. The place of origin of the leaf is called a node; the intervals between nodes are called internodes.

Functions of the Stem.

The primary functions of the stem are support of the leaves, conduction of water and nutrient substances to the leaves and movement of elaborated foods from them. Other functions which may be performed by stems are storage of reserve food, photosynthesis and vegetative reproduction. The regular arrangement of leaves on the stem distributes them in such a manner that they are equally exposed to the light, as is necessary for photosynthesis, (See LEAF: Phyllotaxis.) The stem also supports the flowers in a position for Fig. 3.-Twig pollination and the subsequent

BROOM (RUSCUS)

dissemination of seeds. Conduction of water and nutrient salts from regions of absorption in the roots to the leaves takes place through certain vascular elements of the xylem (tracheae and tracheids) while the movement of synthesized foods from the leaves to other organs of the plant occurs chiefly through the phloem. Radial movement of food within the stem may take place through ray and other parenchymatous cells. Storage of food and water frequently occurs in stems. Examples of food-storing stems are specialized forms such as tubers, corms and rhizomes, and the woody stems of trees and shrubs. Water storage in stems is developed to a high degree in the Cactaceae. All green stems carry on some of the photosynthetic work of the plant, but in most cacti this function is performed chiefly by the stem, the leaves being often present only for brief periods or as

spines. Other plants in which food making is carried on in large measure by the stem are Asparagus and various species of Euphorbia. Where the stem is specialized so that it is flattened and leaf-like it is termed a cladophyll as in butcher's broom or asparagus. Vegetative reproduction is accomplished by many underground stems and is especially common among the Fig. 4.-TRANSVERSE grasses and many members of the lily section of family.

LEAF BUD

Growth and Bud Formation.-Growth in length of the

stem is due to the activity of the apical meristem and to elongation of the internodes; the zone of most rapid growth is at some distance below the apex; below this the rate of growth gradually diminishes until the portion is reached where growth in length no longer takes place. In some cases, as in the stems of grasses, growth in length persists for a longer time in a small re-

gion at the base of the internodes; this is known as interculary growth. In shoots of limited growth, such as those of the larch, the internodes elongate only slightly and the leaves remain close together. Lateral buds give rise to branches, from which others, called branchlets or twigs, arise The terminal bud sometimes dies at the end of one season. and the whole plant, as in annuals, perishes; or part of the axis is persistent, and remains for two or more years, each of the leaves before its decay producing a bud in its axil which continues the growth in spring. In ordinary trees, in which nu-merous lateral buds are formed, any in-Fig. 5.—BRANCH OF jury done to a few branches is easily re-

SLOE (PRUNUS)

paired; but in palms, which form mainly terminal buds, and have no other provision for a lateral formation of them, destruction of the terminal bud results in no further growth of the tree. In the trees of temperate and cold climates the buds which are developed during one season he dormant during the winter, ready to open in the spring. They are generally protected by specialized

leaves in the form of scales, which frequently exhibit a firmer and coarser texture than the foliage leaves. They serve a temporary purpose, and usually fall off sooner or later, after the leaves are expanded. The bud is often protected by a coating of resinous matter, as in the horsechestnut and balsam poplar, or by a thick downy covering, as in the willow. In plants of warm climates the buds are often devoid of any protecting appendages; such buds are called naked. When the terminal bud is injured or ar-

rested in its growth the elongation of the main axis stops, and the lateral branches often acquire increased activity. By conbranches, a woody plant is made to assume Fig 6 - OPUNGIA MONAa bushy appearance, and thus pollard trees CANTHIA are produced. The peculiar bird-nest appearance often presented

by the branches of the common birch depends on an arrestment in the terminal buds, a shortening of the internodes, and a consequent clustering or fasciculation of the twigs. (See GALLS.)

Branching.-The mode in which branches come off from the stems gives rise to various forms of trees, as pyramidal, spreading or weeping-the angles being more or less acute or obtuse. In the Italian poplar and cypress the branches are erect, forming acute angles with the upper part of the stem; in the oak and cedar they are spreading, forming nearly a right angle; in the weeping ash and elm they develop at an obtuse angle; while in the weeping willow and birch they are pendulous, owing to their flexibility The comparative length of the upper and under branches also gives rise to differences in the contour of trees, as seen in the conical form of spruce, and the umbrella-like form of the Italian or stone pine (Pinus pinea).

Branches are sometimes long and slender, and run along the ground, producing buds and adventitious roots at their extremity. This is seen in the runner of the strawberry. In the houseleek (Sempervivum) there is a similar prostrate branch of a shorter and thicker nature, known as an offset, producing a bud at its extremity capable of independent existence. In many instances the branch decays, and the young plant is separated from the parent

Gardeners propagate plants by the process of layering, which

consists in bending a twig, fixing the central part of it into by thin membranous scales. A corm is often only of one year's the ground, and, after the production of roots, cutting off its connection with the parent. A stolon is a branch which curves towards the ground, and, on reaching a moist spot, takes root and forms an upright stem, and ultimately a separate plant This is a sort of natural layering, and the plant producing such hanches is called stoloniferous. In the rose and mint a subterranean branch arises from the stem, which runs horizontally to a certain extent, and ultimately sends up an aerial stem, which may become an independent plant. Such branches are denom-inated rhizomes or suckers, and the gardener cuts the connection between the sucker and the parent stem, to propagate these

In asparagus and other plants which have a perennial stem below ground, subterranean buds are annually produced which appear above ground as shoots or branches covered with scales at first, and ultimately with cladophylls resembling true leaves. These branches are herbaceous and perish annually, while the main stem remains below ground to send up fresh shoots next

In bananas and plantains the aerial stem is a shoot sent up by an underground stem, and perishes after fruiting. Branches are sometimes arrested in their development, and, in place of forming leaves, develop as spines or thorns, as in the hawthorn. Plants which have spines in a wild state, as the apple and pear, often are less spiny when cultivated; in some cases, as in the sloe (Pranus spinosa), a branch bears leaves at its lower portion, and terminates in a spine.

Rhizomes, Corms, Tubers and Bulbs,-Stems are sometimes compressed or flattened laterally, while at other times they are angular. Various terms are applied to the forms of stems, as cylindrical or terete, quadrangular or square, jointed or articulated, etc. The following are some of the more important modifications of stems. A rhizome or rootstock is a horizontal stem

FIG. 7 -RHIZOME OF POLYGONA-

usually sending out numerous adventitious roots and leaf buds from its upper surface. It occurs in ferns, iris, Acorus or sweet flag, ginger, waterlily, many species of Carex, rushes, grasses, anemone, etc. The leaves develop as scales and by their presence, the absence of a rootcap and the presence of a bud at the apex, a rhizome can be distinguished from a root.

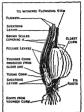

A rhizome such as occurs in Solomon's seal is not the product of a single bud, but is composed of portions of successive axes, the aerial parts of which have died off, leaving their scars. A rhizome sometimes assumes an erect form, as in Scabiosa succisa, in which the so-called praemorse root is in reality a rhizome, with the lower end decaying. The erect rhizome of Cicuta virosa (water hemlock) has hollow internodes, separated by partitions.

In the coral-root orchid Corallorhiza, which grows in soil rich in humus, no roots at all are developed, the coral-like branching rhizome acting as the absorbing organ A tuber is a short thickened stem or branch in which there is little internodal elongation, as in the potato. The eyes of the potato are leaf buds. Tubers are sometimes aerial, occupying the place of branches. The ordinary herbaceous stem of the potato, when cut into slips and planted, sends off branches from its base, which assume the form of tubers. Tubers GORM OF MEA- frequently store up a quantity of starch, as in Maranta arundinacea, whence West

Indian arrowroot is derived. Another form of thickened underground stem is the corm, as seen in the autumn crocus (Colchicum), gladiolus, etc. Structurally it is composed of a solid more or less rounded axis covered

duration, giving off buds annually in the form of young corms. In the axil of the uppermost leaves the flowering stem develops and bears the flowers. The flowering stem dies down, and the young corm from which it arose enlarges greatly at the expense

STEM

FIG. 9 --- CORMS OF COLCHICUM AUTUMNALE

of its parent corm, which thus becomes shrivelled In spring the leaves produced on it, which were merely rudiments in autumn, appear above ground as conspicuous large leaves. At the end of spring these leaves die down, the bases of the lower ones alone remaining as thin brown scales around the corm. Meanwhile, the young bud corm in the axil of the middle leaf grows rapidly at the expense of its parent corm, but it does not attain a great size. In autumn it produces new leaves, which remain small, but from the axil of the upper the flowering stem rises up and bears flowers; while in the axil of one of its middle leaves a new bud corm appears, which will the fol-

AUTUMNALE lowing autumn produce young leaves, flowering stem, and a new bud corm, and thus the cycle

The bulb is a bud which is often subterranean. The axis in this case is much shortened, and the internodes are unelongated. The bases of the leaves rising from the stem are close together, and become succulent and enclose the axis. In the lily the thick and narrow scales are arranged separately in rows, and the bulb is

another in a concentric manner, the outer ones being thin and membranous, and the bulb is tunicated. In the axils of these fleshy scales new lateral shoots arise, forming new bulbs. The lateral buds sometimes remain attached to the axis, and produce flowering stems, so that apparently the same bulb continues to RIFEROUS LILY flower for many years, as in the hyacinth

called scalv: while in the leek, onion and

tulin the scales are broad, and enclose one

and tulip; at other times the young bulbs form separate plants. In the axil of the leaves of Lilium bulbiferum, Dentaria bulbijera, and some other plants, small conical or rounded bodies are produced, called bulbils or bulblets. They resemble bulbs and con-

sist of a small number of thickened scales enclosing a growing point. These scales are frequently united closely together, so as to form a solid mass. The scales in bulbs vary in number. In Gagea there is only one scale: in the tulip and Fritillaria imperialis they vary from two to five; while in lilies and hyacinths there are a great number of them.

PHYLLUM CALYCINUM

Adventitious Shoots.—Adventitious shoots are those which arise elsewhere than in the normal place, as from old stems or roots. Such shoots are frequent on the roots of elm, poplar, plum and other fruit trees. Occasionally adventitious

buds are produced on the edges of leaves, as in Bryophyllum calycinum, Malaxis paludosa, and various species of Asplenium, and on the surface of leaves, as in Ornithogolum thyrsoideum. These are capable of forming independent plants. Similar buds develop on the leaves of Begonia, Gesnera, Gloxinia and Achimens, by wounding various parts of them, and placing them in moist soil; a method pursued by gardeners in their propagation.

other material cut or pierced with a pattern or design, this is laid upon a surface and colour or ink is brushed or rubbed over it, thus leaving the ground colour of the surface imprinted with the design or pattern cut out. In ceramics the stencil is produced by coating the biscuit with a preparation which prevents the transferpaper or enamelling from adhering to the surface at those parts where the original colour of the biscuit is to be preserved

STENDAL, a town in the province of Prussian Saxony, Germany, on the Uchte, 70 mi. W. of Berlin on the main line of railway to Hanover and at the junction of lines to Bremen, Magdeburg and Wittenberge. Pop (1939) 35,691. Stendal was founded in 1151 by Albert the Bear, on the site of a Wendish settlement, and soon afterwards acquired a municipal charter Becoming capital of the Altmark, it rose to a considerable degree of prosperity, in part recently restored to it by its railway connections. The original Wends were gradually fused with the later Saxons.

STENDHAL (1783-1842) the pseudonym of Marie Henri BEYLE, who borrowed the name from a small German town, the birthplace of Winckelmann, and who chose for his epitaph, Qui giace, Arrigo Beyle Milanese; visse, scrisse, amd. He was one of the most original and distinguished of French essayists and novel-

ists. He was born at Grenoble on Jan 23, 1783

From Nov 1796 to 1799, he attended the Ecole Centrale at Grenoble, where he was brilliantly successful. Here he was initiated into mathematics and accurate thinking. He arrived in Paris soon after the 18th Brumaire to study for the Ecole Polytechnique, but he soon gave up this scheme. Pierre Daru, the future grand administrateur of the empire, was a relation and his patron, and obtained a post for him in the War Office; later, in 1799, he sent him to Italy which became the chosen country of this cosmopolitan. He lived at Novara and Milan, in the autumn of 1800 became a sub-lieutenant, but resigned in 1802 and lived in Pans, where he frequented the salons and the theatres After attempting business in Maiseilles, in Aug. 1805, out of infatuation for an actress, he became a deputy to the commissaire des guerres (1806). He then hved for two years beyond the Rhine in Brunswick. He asked vainly for a post in Spain, was appointed auditor to the Conseil d'Etat in 1810, took part in the Russian campaign and became intendent at Sagan in 1813 He had received his baptism of fire in the Alps; he had heard the cannon at Marengo, and seen close at hand the horrors of war at the burning of Ebersberg, Smolensk and Moscow. During the tragic hours at the Beresina, he presented himself, freshly shaved, to Daru, who by this recognized in him an homme de coeur. After the empire fell, having lost all hope of being appointed a prefect, he went to live in Italy (1814-21); he spent six years in Milan, where he became acquainted with Byron, Madame de Stael, Silvio Pellico, Manzoni and Monti, whom he calls "the greatest living poet."

In 1814, he published in Paris les Lettres écrites de Vienne en Autriche sur le célèbre compositeur, Joseph Haydn, suivies d'une vie de Mozart et de considérations sur Métastase et l'état brésent de la musique en France et en Italie, par L. C. A. Bombet. Herein he pillaged Carpani, Schlichtegroll, Winckler and Cramer His plagiarisms would have brought him less reproach if he had acknowledged them more generously. L'histoire de la peinture en Italie, par M.B.A.A. (Beyle, ancien auditeur), appeared in 1817. Stendhal explains and animates the works of the abbé Lanzi and Vasari; he adds trivial or profound reflections to his borrowings from Lavater and Bossi. In Rome, Naples et Florence (1817), Stendhal supplemented his recollections with abundant documentary research; the work contains a wealth of fine, ingenious and vivid impressions on life, music, Italian patriotism, and on the charm of the delicious life he was enjoying. In this respect, this work seems to contain the matter of and to be a commentary on La Chartreuse de Parme.

In 1821 Stendhal was suspected of carbonarisme and espionage, and had to return to Paris. Exiled from his terrestrial paradise in Italy, he visited the houses of La Pasta, de Tracy and Delécluze, and made friends of Mérimée and Jacquemont. A brilliant and paradoxical talker, he both pleased and scandalized. He attempted to reconcile his dandyism with his poverty. He travelled in Eng-

STENCIL, a thin plate or sheet of metal, leather, paper or land in 1821 and 1826 and sent regular accounts and articles to the various English reviews, and to French journals.

He continued to publish literary hack-work the amusing and anecdotal Vie de Rossim (1823) in which his dilettante spirit demanded from music a sentimental pleasure and poetic reverie Les Promenades dans Rome (1829) was a partial success The "cicerone of intelligence and taste" was not content with anecdotes, he described manners, customs and the art of the "chasse au bonheur" in Italy, and the guide may again be seen in the account of the landscapes and monuments which enchanted the author In 1838 appeared Les Mémoires d'un Touriste Stendhal had travelled extensively through France, either alone or in company with Mérimée, who instructed him in the Gothic. In addition to choses vues, the description of his native province, the Dauphiné, and the fair of Beaucaire, the work contains many stories clipped from journals or taken from the impressions of others But it is saved by its vivid and feeling style, and by its "precious nothings" Stendhal also wrote some more original works De Pamour (1822) constitutes under the guise of a psychological and documented analysis, a study and a preface for his novels; physiology is mingled with psychology. In it is also found a curious and original theory of "crystallization," a symbolic picture of the birth and growth of love

Stendhal's first novel was an interesting study of this "crystallization," Armance ou quelques scènes d'un salon de Paris en 1827 (1827) This was followed by a novel dealing with love and ambition—Le Rouge et le Noir (1830). In reading the Gazette des Tribunaux, which he cymcally called "the golden book of French energy in the 19th century," Stendhal had noticed a tragic incident. The son of a farrier of the Dauphine, a former seminarist, had been guillotined at Gienoble on Feb 23, 1828, for having shot and wounded a lady whom he loved On this scandalous material the novelist constructed his story and even wove in some personal confessions, for his Julien Sorel sometimes resembles the author The interest of this novel is found in the energetic spirit of his characters, full of intense and unscrupulous life, in the dramatic adventures, traits of character and passion noted with precision and clearness, and in its psychological analysis

Stendhal had already shown himself to be a pamphleteer was by a real pamphlet that he took his position in the Romantic battle, when he published in 1823 Racine et Shakespeare, which was re-published in 1825 with more vigour and more mordancy than ever. This work was impregnated with the Italian Romanticism of Manzoni, Visconti and Berchet, Stendhal attempted to free the theatre from the "unities" of place and time. He condemned Alexandrine verse and recommended a national tragedy which would be modern, even topical, and by preference liberal These ideas were not all new, but the tone and the accent were completely personal Stendhal had protested against the industrialism of Saint Simon in his witty work D'un nouveau complot cont, e les industriels (1825)

Shortly after the revolution of July 1830 Stendhal was appointed consul at Trieste, but since Metternich refused him his exequatur, he was sent in April 1831 to Civita-Vecchia There he longed for Paris, the city of conversation. He wandered about Naples, made excavations in the papal territory, continually visited Rome and took holidays in Paris between 1836 and 1830. He had not yet had any true success when he was hailed as a great novelist by Balzac in an article published on Sept. 25, 1840, in the Revue Parisienne, on the Chartreuse de Parme. He had just completed an advantageous contract with the Revue des deux Mondes for "nouvelles" when he was overcome on the boulevard by an attack of apoplexy on March 22, 1842 Three friends, including Mérimée, followed his funeral to the cemetery of Montmartre. He counted on obtaining a little glory about 1880 or even later. "I take a ticket in the lottery, the grand prize of which may be summed up as-to be read in 1935.

He was read long before this, and La Chartreuse de Parme is one of the great romances of the 19th century. The hypothesis which saw in it only an ingenious reproduction of ancient Italian chronicles which Stendhal had dug out of the libraries bas been exploded. The value of the novel lies in the analysis of the grandes

bassions and in his pictures of contemporary manners. It differs widely from the rude and simple stories which he liked to take as his inspiration Stendhal has put in this book his experiences and intimate feelings, his impressions of Italy revived by nostalgia This book was seven years in contemplation and it was finally written in Paris in seven weeks, appearing in April 1839 The first part of the book consists of memories rearranged by the authorof Milan on the morrow of Lodi, of the adventures of Fabrice. present at a great battle without seeing much of it, of France after Waterloo, of the intrigues of a little Italian court in 1820 The book is full of Stendhal's reading on Italy of former days which gives rise to certain discrepancies. The actors are original characters, even if one sees the prototype of Count Mosca in Metternich or in Count Sauron, the governor of Lombardy The Duchess of Sanseverma differs greatly from la Vannoza, the mistress of the future Pope Alexander VI., and Fabrice del Dongo, the Napoleonic marquis who became a priest after taking part in a consuracy, has more resemblance to Julien Sorel than to Alexander Farnese Stendhal excels in the delineation of souls and of exceptional and complex characters, scheming and energetic Portraits, landscapes and Italian life play a large part in this crowded and disconcerting romance. The style is always natural, clear and hmoid. The "little precise phrases, worthy of a code or of algebra" raised the enthusiasm of Taine who regarded Stendhal as a

From his "Italian chronicles" he repeatedly drew dark and bloody stories and hornble and romantic novels. He was amused by these stories which he published between 128.9 and 138.9 in the Revuse de Pars. Vanina 'Parus, Le cofre et le revenud. Le Philtre. Vittoria Accormbons, Les Cenci, Le duchesse de Palidon, L'Abbass de Castro, San Francesco a Rije, appeared in the

Revue des deux Mondes (1837-53)

"superior spirit'

Skendhal's admirers have published his unpublished works and even some illegible fragments preserved in the bloray at Gerosolic. With audacous disqueeting sincerty, sometimes bordering on cyndism, Stendhal wrote authorigaphies entitled La Vis d'illent Brutard (1890), Souvenir d'Egotisme (1892), Lucien Leuwen (1894), Journal d'Itale (1911), in order to enjoy his past and to rescue from oblivion his "so different" personality. Lames (1889) is a romance in the style of Blasta and Suc et a founding-child of a edituced peasant woman. In his correspondence, vivid, primitive, amusing, passing from roury to tendences, he patre himself with somewhat crude freedom. It is a feast for lovers of human documents. A place apart must be given to the Letter's Planting, the confident. La Vis de Napoléon (1876) is less original than might have been expercied. History is minzeled with letteral and onsoin

Stendhal, the "husar of romanticam," independent of all schools, was to none behind the times and a pioner Disciple of the ideologues and even of the philosophers of the 18th century, he nevertheless seems to have been in advance of our own generation. Almost unknown during his lifetime, Stendhal the psychologist, an expert in unarveiling and analyzing the sentiments of the imman heart, curious about the "little true facts," careful to "write philosophically" for a statistion dilite, for the "happy few," was one of the introducers of romanticism and of the psychological novel. It was all very well for him to write that "a novel is a mirror taking a walk along the high road"; his mirrors possessed a strange magic, Of him more than anyone else it may be said that the was original. There are "Stendhallens" and "anti-Stendhallens". Heart Beyle lives to-day more than 100 years ago.

BILLIOGRAPHY.—Stendhal's works have been published in 17 vols. by Michel Levy (1858–85). They were republished from 1703 under the direction of Paul Arbeite and Educard Champein (1958–195). The following the control of the paul Stender of the Caucard of th

or also a single stroke. The keys are so

arranged that the initial consonants are under the fingers of the left hand, the vowels under the thumbs, and the final consonants under the fingers of the right hand Duphcation of consonants accounts for the five additional keys. The machine weighs only

about 54lb. and is correspondingly small.

STENTOR, one of the Greeks before Troy (Iliad v. 783),
whose "stentorian" voice was as loud as that of so men

STEPHAN, HEINRICH VON (1831-1897), German statesman, was born at Stolp, Fomerana, on Jan. 7, 1831. He entered the Prussian postal service, in which he rose sapidly. He was the first postmaster-general of the German Empire and was the chief promoter of the International Postal Union, presiding at the first conference, at Bern, m 1874. He died on April 8, 1897. See E Knickeberg, H. v Stephan (1897).

STEPHANITE, a mineral consisting of silver subphantimonite, AgaSbS; containing 68 5% of silver, and sometimes of importance as an one of this metal Under the name Schwarzerz (black ore) it was mentioned by G. Agricola in 1346 The stephanite mineral has a hardness of a-5 and is very brittle, the specific gravity is 6-3. It occurs with other ores of silver in metalliferous veins, as in the Comstock lode in Nevada

STEPHANUS BYZANTINUS (SYEPHEN OF BYZAN-TULK), the author of a geographical dictionary entitled Ebongorius, of which, apart from some fragments, we possess only the meagre entitome of one Hermolaus, dedicated to Justinian; whether to the first or second emperor of that name is disputed. Stephanus probably flourished in the earlier part of the 6th century, under Justinian I The chief fragments remaining of the original work (which contained quotations from classical authors and topographical and historical details) are preserved by Constantine Porphyrogenetics, De administration imperior, ch. 23 (the article 'Tāpilau bio) and De thematibus, ii to (an account of Sicily); the latter includes a passage from the comic poet Alexis on the Seven Largest Islands, Another fragment, from the article Δiphy to the end of A, exists in a mos of the Sequerian library.

See E. H. Bunbury History of Ancient Geography, 1, 102, 135, 169; ii. 669-671 (1883), Riese, De Slephani Byzant. auctoribus (Kiel, 1873); J. Gefficken, De Stephano Byzantio (Göttingen, 1886).

STEPHEN, in some senses the greatest figure in primitive Christianity prior to Faul's conversion, was one of "the Seven" (Acts xxi. 8, nowhere called "deacons") set over the "daily miniration" towards the needy members of the Jerusalom community. Like Philip and perhaps others of his colleagues (vi. 3), he had higher gifts than his office would suggest He was "full of faith and of holy Spirit"; and as his spiritual power showed itself in mighty deeds as well as words (vi. 5, 8), he became a harked man in Jerusalem Himself a Jew of Greek culture, he naturally tried to win over his fellow Hellenists (vi. 9).

It is here that Stephen's advance upon prior Apostolic teaching becomes apparent. His special "wisdom" lay in greater insight into the merely relative nature and value of the externals of Israel's religion, particularly those connected with the Temple. His fellow Hellenists, as a body, were eager to disprove the feel-

ing of the native "Hebrews" that they were only half Jews Hence teaching which minimized the value of the sacred "customs which Moses had delivered" (vi. 14), by making "salvation" depend simply on faith in Jesus as Messiah, would cause deep resentment in such circles, in spite of their more liberal attitude to things non-Jewish. For in Jerusalem the Temple overshadowed men's thoughts touching the Divine presence To this he would reply in the spirit of the prophets, that the heart is the true seat of the Shekmah; and that if they refused God manifest in His Messiah, no holy "customs"-no, not the Temple itself-could save from the displeasure of the living God Nay, he argued, quoting words of Jesus (Matt xxvi 61, Mk xiv 58, Jo ii. 10) which were easy to misquote (Acts vi 14), that the Temple might even be destroyed, as it had been in the past, without loss to true religion. But they could not rise to this conception and treated his words as "blasphemous," and roused "the people and the

384

elders and the scribes" against him He was seized and brought before the Sanhedrin on the charge of speaking "against the Temple and the Law" (vi II-I4). His defence took the form of a survey of Israel's religious past, with a view to show: (1) that "the God of Glory" had covenant rela-tions with their forefathers before they had either Holy Place (Land or Temple) or Law (vii. 1-17); (2) that the first visible meeting place between God and His people was far other than that for which absolute sanctity was now claimed. Indeed, the form of "the tabernacle of testimony in the wilderness" (no Holy Land) had more divine sanction than any later Temple (44-47); (3) that, after all, the presence of "the Most High" was not bound up with any structure of human hands, as Isaiah witnessed (48-50). The moral of all this was plain: Israel's forms of fellowship with the Most High had all along been relative and subject to change. Hence there was no "blasphemy" in suggesting that in the Messianic age yet another change might come about, and that observance of Temple services could prove little as to acceptance with God. But there is another and more urgent line of pleading. This is found in the elaborate section dealing with the person and work of Moses, the great lawgiver (17-38)-a section full of extra-biblical touches-followed by one on Israel's hardness of heart towards him, together with its result, the Exile (39-43). Pure and original Mosaism is represented as something which in its full spiritual intention had been frustrated by Israel's stiffneckedness (39, 42 seq.). The figure of Moses is made to stand forth in ideal outlines, the thinly-veiled Christian application shining through. "This is that Moses who said unto the children of Israel, 'A prophet shall God raise up unto you . . . like unto me.' who received living oracles to give unto us: to whom our fathers would not be obedient, but thrust him from them, and turned back in their hearts. . . . " (38 seq.). Here we have the very situation as between Stephen and his hearers, and it is made unmistakable by the speaker's closing words (51-53). Had they kept the Law dutifully, they would have believed on Him in whom true Mosaism was fulfilled and transcended. The author of Acts probably owed his report of Stephen's speech (as of his whole story) to Philip the "evangelist," who had been one of the Seven (xxi 8). Possibly also Paul had spoken in Luke's hearing of Stephen's death and his own part in it (vii. 58, 60, cf. vi. 9).

Stephen's martyrdom is described as tumultuary in character, though the legal forms of stoning for blasphemy were observed (via. 58); nor is it inconceivable that an act exceeding Jewish rights under the Romans should have taken place at the sudden impulse of religious fanaticism.

STEPHEN, the name of nine popes.

STEPHEN I., bishop of Rome from about 254 to 257, followed Lucius I. He withdrew from church fellowship with Cyprian and certain Asiatic hishops on account of their views as to the necessity of rebaptizing heretics (Euseb. H. E. vii. 5; Cypr. Epp. 75). He is also mentioned as having insisted on the restoration of the bishops of Merida and Astorga, who had been deposed for un-faithfulness during persecution but afterwards had repented. He is commemorated on August 2. His successor was Sixtus II

STEPHEN III (II), pope from March 752 to April 757, was in deacon's orders when chosen to the vacant see within 12 days after the death of Zacharias 1 The main difficulty of his pontificate was in connection with the aggressive attitude of Aistulf, king of the Lombards The death of Stephen took place not long after that of Aistulf He was succeeded by Paul I

STEPHEN IV (III), pope from Aug. 7, 768, to Feb 3, 772, was a native of Sicily, and, having come to Rome during the pontificate of Gregory III, gradually rose to high office in the service of suc-

cessive popes He was succeeded by Adrian I.

STEPHEN V (IV), pope from June 816 to Jan. 817, succeeded Leo III He did not continue Leo's policy, which was more favourable to the clergy than to the lay aristocracy. Immediately after his consecration he ordered the Roman people to swear fidelity to Louis the Pious, to whom he found it prudent to betake himself personally in the following August After the coronation of Louis at Reims in October he returned to Rome, where he died in the beginning of the following year. His successor was Paschal I.

STEPHEN VI (V), pope from 885 to 891, succeeded Adrian III, and was in turn succeeded by Formosus In his dealings with Constantinople in the matter of Photius, as also in his relations with the young Slavonic Church, he pursued the policy of Nicholas I.

STEPHEN VII (VI), pope from May 896 to July-August 897, succeeded Boniface VI, and was in turn followed by Romanus. His conduct toward the remains of Formosus, his last predecessor but one (see Formosus) excited a tumult, which ended in his imprisonment and death by strangling.

STEPHEN VIII (VII) (Jan 929 to Feb. 931) and STEPHEN IX (VIII) (July 939 to October 949) were virtually nonentities, who held the pontificate while the real direction of the pontifical state was in the hands of Marozia and, afterward, of her son Alberic,

senator of the Romans

STEPHEN X (IX), pope from August 1057 to March 1058, succeeded Victor II (Gebhard of Eichstädt) His baptismal name was Frederick, and he was a younger brother of Godfrey, duke of Upper Lorraine, marquis of Tuscany (by his marriage with Beatrice, widow of Boniface, marquis of Tuscany) Frederick, who had been raised to the cardinalate by Leo IX., acted for some time as papal legate at Constantinople, and was with Leo in his unlucky expedition against the Normans He shared his brother's fortunes, and at one time had to take refuge from Henry III. in Monte Cassino Five days after the death of Victor II he was chosen to succeed him He showed great zeal in enforcing the Hildebrandine policy as to clerical celibacy. He died at Florence on March 29, 1058.

STEPHEN (1097?-1154), king of England, was the third son of Stephen Henry, count of Blois and Chartres, and, through his mother Adela, a grandson of William the Conqueror. Born some time before 1101, he was still a boy when he was taken into favour by his uncle, Henry I. of England, and received the honour of knighthood and the county of Mortam. In 1118 he severed his connection with Blois and Chartres, renouncing his hereditary claims in favour of his elder brother Theobald But he acquired the county of Boulogne by marrying Matilda (c. 1103-1152), the heiress of Count Eustace III and a niece of Henry's first wife. The old king arranged this match after the untimely loss of his son, William Atheling, in the tragedy of the White Ship; until 1125 Stephen was regarded as the probable heir to the English throne. But on the return of the widowed empress Matilda (q.v.) to her father's court, Henry compelled Stephen and the rest of his barons to acknowledge her as their future ruler (1126). Seven years later these oaths were renewed; and in addition the ultimate claims of Matilda's infant son, Henry of Anjou, were recognized (1133). But the death of Henry I. found the empress absent from England Stephen hurried across the Channel and began to canvass for supporters, arguing that his oaths to Matilda were taken under coercion, and that she, as the daughter of a professed nun, was illegitimate

He was raised to the throne by the Londoners, the official <sup>1</sup>A priest named Stephen, elected before him, died three days after, without having received the episcopal consecration. haronage and the clergy, his most influential supporters were the old justiciar, Robert, bishop of Salisbury, and his own brother Henry, bishop of Winchester Innocent II, was induced by Bishop Henry to ratify the election, and Stephen thus cleared himself from the stain of perjury. Two charters of liberties, issued in rapid succession, confirmed the King's alliance with the Church and earned the good will of the nation. But his supporters traded upon his notorious facility and the unstable nature of his power. Extortionate concessions were demanded by the great barons, and particularly by Earl Robert of Gloucester, the half-brother of the empress The clergy insisted that neither their goods nor their persons should be subject to secular jurisdiction. Stephen's attempt to create a mercenary army and a royalist party led at once to a rupture between himself and Earl Robert (1138), which was the signal for sporadic rebellions Soon afterwards the king attacked the bishops of Salisbury, Ely and Lincoln-a powerful family clique who stood at the head of the official baronageand, not content with seizing their castles, subjected them to personal outrage and detention The result was that the clergy, headed by his brother, the bishop of Winchester, declared against him (1139).

Stephen was thoroughly discredited when the empress at length appeared in England (Sept. 30, 1139) Through a misplaced sense of chivalry he declined to take an opportunity of seizing her person. She was therefore able to join her half-brother at Gloucester, to obtain recognition in the western and south-western shires, and to contest the royal title for eight years Stephen's mitial errors were aggravated by bad generalship. He showed remarkable energy in hurrying from one centre of rebellion to another, but he never ventured to attack the headquarters of the empress In 1141 he was surprised and captured while besieging Lincoln castle. The empress in consequence reigned for six months as "Lady (Domina) of the English"; save for her faults of temper, the cause of Stephen would never have been retrieved. But, later in the year, his supporters were able to procure his release in exchange for the earl of Gloucester. After an obstinate siege he expelled Matilda from Oxford (Dec. 1142) and compelled her to fall back upon the west.

The next five years witnessed anarchy such as England had never before experienced England north of the Ribble and the Tyne had passed into the hands of David of Scotland and his son, Prince Henry; Ramilf eral of Chester was constructing an independent principality; on the west the rauds of the Angevin party, in the east and midlands the excesses of such rebels as Geoffrey de Mandeville, earl of Essex, turned considerable districts into widelensesses. Meanwhile Geoffrey of Anjou, the bushand of the empress, completed the conquest of Normandy (r144). In 1747 the situation improved for Stephen; Robert of Gloucester, the ablest of the Angevin partisans, died, and the empress left England in despair. But her son soon appeared in England to renew the struggle (1749) and conciliate new supporters. Soon after his return to Normandy Henry was invested by his father with the duchy (1750). He succeeded to Anjou in 1751; next year he acquired Aquitaine by marrage.

Skephen struggled hard to secure the succession for Eustace, his elder son. But he had quarrelled with Rome respecting a vacancy in the see of York; the pope forbade the English bishops to consecrate Eustace (1751), and there was a general unwillingness to prolong the civil war. Worn out by incessant conflicts, the bowed to the inevitable when Henry next uppeared in England (1753). Negotiations were opened; and Stephen's last hesitations disappeared when Eustace was carried off by a sudden illness. Late in 1133 he king acknowledged Zurud and the superior of the superior of the superior of the property of the superior of the superior of the property of the superior of the superi

manthy; but Stephen died soon thereafter (Oct. 175).
On his great seal Stephen is represented as sall and robust, bearded, and of en open countenance. He was frank and generous; his occasional arts of duplicity were planned reluctantly and newer carried to their logical conclusion. In warfare he showed courage, but little generability; as a stateman he falled in his

dealings with the Church, which he alternately humoured and thwarted. He was a generous patron of religious foundations; and some pleasing anecdotes suggest that his personal character deserves more commendation than his record as a king

deserves more commendation than his record as a king See the Grist Stepham, Richard of Heicham, Aefred of Riewaux' Ratati de Standardo, aid the chronicle of Robert de Torigni, all London, 1884-99.) STEPHEN I. [ST STEPHEN] (977-1038), king of Hungary, was the son of Geas, duke of Hungary, and of Sarolta, one of the few Magyar Christian ladies. His tutiors included the German priest Bruno, the Cach priest Radia, and an Italian knight, Theodate of San Severino, who taught him arms and letters. In 96 Stephen married Gisela, the daughter of Duke Henry II of Bavaria. In the following year his father died and the young prince was confronted by a formidable pagar reaction between the Drave and Lake Balaton. Stephen hastened against the rebots bearing before him the banner of St. Martin of Tours, whom how chose to be his patron sant, and routed the rebels at Veszerre (998), assuming the royal title immediately afterwards.

The rest of Stephen's life was spent largely in a struggle against the pagan nobles, which engrosed his energies, and compelled him to adopt a pacific policy towards the emperors of the East and West, but when attacked by the emperor Conrad in 103 Stephen repelled the invasion successfully. He died at Exstergom in 1038 and was canonized in 1083. For an account of his reforms see Huxnaxy: History.

STEPHEN V. (1239-1272), king of Hungary, was the eldest son of Bela IV, whom he succeeded in 1270. In 1261, as crown prince, he had compelled his father, whom he had assisted in the Bohemian War, to surrender 92 counties to him, virtually dividing Hungary into two kingdoms; while afterwards he sexued the southern banate of Macso, which led to a fresh war between father and son in which the latter triumphed. In 1268 he invaded Bilgaria and assumed the title of king of Bulgaria. During his father's lifetime Stephen had a double matrimonial alliance with the Netpolitian princes of the House of Anjou, the chief partisans of the pope. He certainly needed exterior support; for on his accession to the Hungarian throne he encountered almost universal hostility owing to his alleged pagan leanings, due largely to the influence of his Cuman wite Elizabeth, to whom his father had married him for political reasons in 1255. The malcontents combined with Citakar II. of Bohemia, and invagded western Hungary; but Stephen routed Ottakur at Mosony (1271) and was preparing to recover his minat son Laddislaus whom the rebels

had kidnapped, when he died suddenly on Aug 6, 127; STEPHEN, SIR JAMES FITZJAMES, Boxr. (1829— 1894), English lawyer, judge and publicist, was born in London on March 3, 1829, the third child and second son of Sir James Stephen. He was educated at Elon, London university, and Trinity, Cambridge. He was already acquainted with Sir Henry Maine (zv.), six years his senior, and then newly appointed to the chair of civil law. This acquaintance now ripened into a perfect friendship, which ended only with Maine's death in, 1838.

Stephen was called to the bar in 1854, and in 1859 he was appointed recorder of Newark. In 1856 he published his General View of the Criminal Law of England (and recast ed. 1850). This was the first attempt that had been made since Blackstone to explain the principles of English law and justice in a literary form, and it had a thoroughly deserved success 'all this time Stephen kept up a great deal of miscellaneous writing, and the Goundation of the Pall-Madl Gasatte in 1865 gave him a new

field The decisive point of his work was in the summer of 1869, when he accepted the post of legal member of council in India. Fitzjames Stephen's friend Mame was his immediate predecessor in this office Guided by Maine's comprehensive genius, the government of India had entered on a period of systematic legislation which was to last about twenty years The materials for considerable narts of this india had been left by Maine

Stephen had the task of working them into their definite shape and conducting the bulls through the Legislative Council. This did with wonderful energy, with efficiency and workmanship adequate to the purpose, if sometimes rough according to English notions, and so as to leave his own individual mark in many places. The Native Marriages Act of 1892 was the result of deep consideration on both Maine's and Stephen's part. The draft of the Contract Act was materially altered in Stephen's shands begin also in 1872, it became law. The Evidence Act of the same year was entirely Stephen's part. The Contract also in 1872, it became law. The Evidence Act of the same year was entirely Stephen's part. The Contract also in 1872 in the came home in 1872.

Indua experience had supplied Stephen with the motive for his next piece of work, which historians of the common law may well regard as his greatest tutle to remembrance. The materials which Stephen had long been collecting took permanent shape in the History of the Criminal Law of England (1832), which, though not free from inequalities and traces of haste, must long remain the standard work on the subject. The Bills of Exchange Act (1832), the State of Goods Act (1832) and the Manne Insurance Act (passed 1906) are indirectly due to his efforts in 1879 Stephen became judge of the queen's bench division. He respired that office in April 1891, after a long life with a surprising amount of work, of which a large proportion was of permanent value. He married Mary Cunningham in 1855.

"See Ser Lesko Stephen, Life of Sr James Patiziones Stephen (London, 1855), with bibbegraphical appendix, a model biography; same author's article in the Dict. Not. Blog; Letter with biographical Notes, by his daughter, Canoline Emelas Stephen (1907). See also Sir C. P. Ilbert, "Sir James Stephen as a Legislator," Law Quert. Rev. X. 222.

STEPHEN, SIR LESLIE (1832-1904), English philosopher and man of letters, son of Sir James Stephen, was born in London on Nov. 28, 1832. He was educated at Eton, at King's college, London, and Trinity Hall. Cambridge. In 1854 Stephen obtained a Goodbehere fellowship, and was ordained deacon on Dec. 27, 1855, becoming a priest in 1859 In 1856 he was admitted to a junior tutorship at Trinity Hall. He was a good athlete and a mountaineer His first ascent was in 1857 (Col du Géant), and he made many others in the following years, until his first marriage in 1867. He was president of the Alpine club from 1865 to 1868, and editor of the Albine Journal from 1868 to 1871 His accounts of his mountaineering feats were published in various journals, and collected in The Playground of Europe (1871). In the meantime, during his residence at Trinity Hall, his philosophical studies led him to abandon the orthodox theological position, and in 1875 he relinquished his orders. He interested himself in university politics, and advocated the need for examination reforms. During the American Civil War he was greatly in sympathy with the North, and in 1863 visited America to investigate the situation On his return he published *The Times* and the American War by L. S. (1865), in answer to English arguments in support of the South. Stephen came to London in 1864, with useful recommendations from his brother Sir J. Fitzjames Stephen. He contributed for many years to the Saturday Review, and from 1865 co-operated with George Smith in the foundation of the Pall Mall Gazette. From Oct 1866 to Aug 1873 he contributed political articles to the Nation. His literary criticisms for the Cornlill Magazine (from 1866) were collected from time to time in separate volumes, as Hours in a Library (1874, 1876 and 1879). In 1871 he became editor of the Cornhill, and during the II years of his editorship the magazine made a reputation by its literary excellence. R. L Stevenson; Thomas Hardy, Henry James and Edmund Gosse were among his contributors. In his Essays on Free Thinking and Plain Speaking (1873) Stephen challenged the dogmas of popular religion His

Hastory of English Thought in the Eighteenth Century (2 vols., 1850), later extended unto The English Utilitations (1900), remains a standard work on the subject He married in 1857 the younger daughter of W. M. Thackersy, and in 1868 visited America with her, where he met Emerson and Oliver Wendell Holmes, the voumer

In Nov 1882 George Smith made Stephen editor of the Dictionary of National Biography, which he conducted until April 1801, continuing to contribute until 1901. His first wife died in 1875, and in 1878 he mairied again. In his later years he was greatly affected by the death first of his brother James (1894), and shortly afterwards (1895) of his wife. One of his daughters, Mrs Virginia Woolf, is separately noticed in this book. Stephen received many marks of distinction, and in 1902 was made K C B. He continued his literary work almost to the end of his life, and his last books were a monograph on Hobbes (1904), and his Ford lectures, English Literature and Society in the Eighteenth Century, published on the day of his death, Feb 22, 1004 His work, both philosophical and literary, is remarkable for the sincerity of the author's outlook, and for his unprejudiced Judgments He wrote also Social Rights and Duties (1896); Science and Ethics (1882): An Agnostic's Apology (1893); Studies of a Biographer (2 vols, two series, 1899 and 1902), and monographs for the "English Men of Letters" series.

See F W Maitland, Life and Letters of Leshe Stephen (1906), Sir Sidney Lee, Principles of Biography (the Leshe Stephen lecture, 1911).

STEPHEN (ISTVÁN) BÁTHORY (1533-1586), king of Poland and prince of Transvlvania Bathory spent his early years at the court of the emperor Ferdmand, subsequently attached himself to Janos Zapolya, and won equal renown as a soldier and diplomatist Zapolya rewarded him with the voivodeship of Transvlvania, where his defence of the rights of his patron's son, John Sigismund, incurred the animosity of the emperor Maximilian, who kept him in prison for two years On May 25, 1571, on the death of John Sigismund, Bathory was elected prince of Transvivania by the Hungarian estates, in spite of the opposition of Vienna He expelled the rival candidate, Gaspar Békesy, from Transylvania (1572) In 1579 the Polish nobility, at the instigation of Zamoyski (q.v.) elected Bathory king of Poland, in opposition to the emperor Maximilian, the candidate of the senate Báthory persuaded the Transylvanian estates to elect his brother Christopher in his stead, hurried to Cracow, espoused the princess Anne, the sister of the last Jamello, and was crowned on May 1.

The leading events of Stephen Báthory's reign can here only be briefly indicated All armed opposition colleged with the surrender of Danzig, after a six months' siege, on Dec. 16, 1577. Stephen was now able to devote himself to foreign affairs. The difficulties with the sultan were temporarily adjusted by a truce signed on Nov 5, 1577; and the Diet of Warsaw having voted supplies, Stephen embarked on war with Muscovy. Penetrating to the heart of the country, be besseged Pskov (Aug.—Dec. 1581), and forced Ivan the Terrible to cede him Polotsk and Livonia (peace of Zapoli, Jan. 15, 1582). The chief domestic event of Stephen's reign was the establishment in Poland of the Jesuits, in furtherance of his designs of uniting Poland, Muscovy and Transylvania into one great state The project was dissipated by his sudden death, of apoplexy, Dec. 12, 1586.

Hausyvania into the gical scale. The project was dissipated by his sudden death, of apoplexy, Dec. 12, 1586

See I. Polkowski, The Martial Exploits of Stephen Bdishory (Pol., Cracow, 1837); Paul Pletling, Un Arbitrage pontifical an xome siècle (Brussels, 1890); Lajos Saddorky, Stephen Bdishory's Election to the Crown of Poland (Hung; Budapest, 1887)

STEPHENS, ALEXANDER HAMIL TON (1812-1882). American statesman, were president of the Confederate States during the Civil War, was born in Wilkes (now Talanferro) country, Georgia, on Feb. 11, 132. He was a weak and sickly child of poor parents, and from his sixth to his 15th year, when he was left an orphan, he worked on a farm. After his father's death he went to live with an uncle in Warren country. The superintendent of the local Sunday school sent him to an academy at Washington, Wilkes country, for one year and in the following year (1848) he was sent by the Georgia Educational society to Franklin college (University of Georgia), where he graduated in 1832. Deciding

not to enter the ministry, he paid back the money advanced by view to discovering and examining the antiquities said to exist was admitted to the bar in 1834.

In 1836 he was elected to the Georgia house of representatives after a campaign in which he was vigorously opposed because he had attacked the doctrine of nullification, and because he had opposed all extra-legal steps against the abolitionists. He was annually re-elected until 1841; in 1842 he was elected to the State senate, and in the following year, on the Whig ticket, to the national House of Representatives In this last body he urged the annexation of Texas, chiefly as a means of achieving more power for the South in Congress He was denounced as a traitor to his party because of his support of annexation, but he later became the leader of the Whig opposition to the war with Mexico. He vigorously supported the Compromise Measures in 1850, and continued to act with the Whigs of the North until they, in 1852, nominated Gen Winfield Scott for the presidency without Scott's endorsement of the Compromise Stephens and other Whigs of the South then chose Daniel Webster, but a little later they joined the Democrats In 1854 Stephens helped to secure the passage of the Kansas-Nebraska Bill Before the Georgia legislature in Nov 1860, and again in that State's secession convention in Jan. "1861, he strongly opposed secession, but when Georgia seceded he "followed his state," assisted in forming the new government, and was elected vice president of the Confederacy Throughout the war, he was so concerned about States' rights and civil liberty that he opposed the exercise of extra-constitutional war powers by President Jefferson Davis lest the freedom for which the South was fighting should be destroyed. His policy was to preserve constitutional government in the South and strengthen the antiwar party in the North by convincing it that the Lincoln administration had abandoned such government; to the same end he urged, in 1864, the unconditional discharge of Federal prisoners in the South. Stephens headed the Confederate commission to the peace conference at Hampton Roads in Feb. 1865 In the following May, after the fall of the Confederacy, he was arrested at his home and taken to Fort Warren, in Boston harbour, where he was confined until Oct. 12 In 1866 he was elected to the United States Senate, but was not permitted to take his seat. He was a representative in Congress, however, from 1873 to 1882, and was governor of Georgia in 1882-83, dying in office, at Atlanta, on March 4, 1883.

From 1871 to 1873 he edited the Atlanta Daily Sun, and he published A Constitutional View of the Late War between the States (1868-70), perhaps the best statement of the Southern position with reference to state sovereignty and secession, The Reviewers Reviewed (1872), a supplement to the preceding work; and A Compendium of the History of the United States (1875; new ed., 1883)

STEPHENS, JAMES (1882-1950), Irish poet, was born in Dublin. He was earning his living as a clerk in Dublin when he made his name by the exquisite prose of the delightful fairy stories published as The Crock of Gold (1912). He shows a sense of fantasy and a delicate poetic talent in all his works. The later ones include Reincarnation (1918); Deirdre (1923); In the Land of Youth (1924); Collected Poems (1926) and Etched in Moonlight (1928). Stephens was an ardent Nationalist and supported the Irish Free State. He died in London on Dec. 26, 1950.

STEPHENS, JOHN LLOYD (1805-1852), American traveller, was born Nov. 28, 1805, at Shrewsbury, N.J. Having been admitted to the bar, he practised for about eight years in New York city. In 1834-36 he made extensive travels in Europe, STEPHENSON, ROBERT (1803-1859), English engineer, Egypt and Syria. In 1839 Stephens arranged with Frederick only son of George Stephenson (q.v.), was born at Willington

the society He was a schoolmaster for about two years, and then there. Supplies, meantime, was appointed to a mission to central America. Stephens published in 1841 Incidents of Travels in Central America, Chiapas and Yucatan. A second visit (1841) to Yucatan is described in Incidents of Travel in Yucatan (1843) Stephens died at New York on Oct 10, 1852

STEPHENSON, GEORGE (1781-1848), English engineer, was the second son of Robert Stephenson, fireman of a colliery engine at Wylam, near Newcastle, where he was born on June 9, 1781 In boyhood he was employed as a cowherd, and afterwards he drove the "gin-horse" at a colliery. At 14 he became assistant fireman to his father at a shilling a day, and at 17 he was appointed plugman, his duty being to attend to the pumping-engine. As yet he was unable to read, but stimulated by a desire to study the inventions of Boulton and Watt, he attended a night school and made rapid progress. In 1801 he became brakesman, in 1802 engineman at Willington Quay, where he took up watch and clock cleaning in his spare time. In 1804 he moved to Killingworth, where in 1812 he was appointed engine-wright of the High Pit at a salary of £100 a year. It was here in 1815 that he devised his miner's safety lamp, at the time when Sir Humphry Davy was also producing his lamp, a coincidence which led to much controversy.

In 1813 Stephenson was authorised to build a "travelling engine" for the tramroads between the Killingworth colliery and the port 9 mi away on the plan of one already running at Wylam The engine, which was named "Blucher," ran a successful trial on July 25, 1814, and in 1822 he persuaded the directors of the Stockton and Darlington railway (then in construction) to use steam instead of animal traction At the opening of this railway on Sept. 27, 1825, therefore, the first public passenger train in the world was drawn by Stephenson's locomotive "Active," which was subsequently renamed "Locomotion" His connection with the Stockton and Darlington led to his employment on the Liverpool and Manchester railway, whose track he carried successfully over Chat Moss When the line was nearing completion he persuaded the directors, who favoured haulage by fixed engines, to give the locomotive a trial They offered a prize of £500 for a suitable machine, and in the Rainhill trials in October, 1829, Stephenson's engine, "The Rocket," was chosen. (For a description see Steam Engine) On September 15, 1830, the railway was formally opened, the eight engines employed having been built at the works started at Newcastle in 1823 by Stephenson, his cousin Thomas Richardson, and Edward Pease Stephenson was engineer of the Grand Junction, London & Birmingham (with his son Robert), Manchester to Leeds, Derby to Leeds, Derby to Birmingham, and Birmingham to York railways; but he strongly disapproved of the "railway mania" of 1844. He was also consulted about the construction of railways in Belgium and Spain. The last years of his life were spent in retirement at Tapton Flouse, Chesterfield, in farming and horticulture, and there he died on Aug. 12, 1848.

See Life of George Stephenson, by Samuel Smiles (1857, new ed., 1881); and Smiles's Lives of the Engineers, vol v. (1873).

STEPHENSON, GEORGE ROBERT (1819-1905), British civil engineer, was born at Newcastle-on-Tyne on Oct. 20. 1819, and was the nephew of George Stephenson (1781-1848) (q.v.). After working in colliery workshops near Manchester, he was sent to King William's School, Isle of Man. After his father's death in 1837, he worked for his uncle in the drawing-office of the Manchester and Leeds railway. In 1860, when he was consulting engineer to the provincial government of Canterbury, New Zealand, the Lyttelton-Christchurch line was built under his direction. He returned to England, and with Sir John Hawkshaw in 1864 built the East London railway. He was partly responsible for the construction of the Victoria tubular bridge across the St. Lawrence, and designed many bridges in England and abroad. In 1859 he succeeded his cousin Robert Stephenson (q.v) at the locomotive works at Newcastle-on-Tyne, and at the Snibston and Tapton collieries He died at Cheltenham on Oct. 26, 1905.

Catherwood to make an exploration in central America, with a Quay on Oct. 16, 1803. He spent four years at school in New-

castle, and was then (1819) apprenticed to Nicholas Wood, a coal-viewer at Killingworth, after which he was sent in 1822 to attend science classes at the university of Edinburgh. He assisted his father in surveying the Stockton and Darlington and Liverpool and Manchester railways, and in 1824 he took charge of the engineering operations in South America of the Colombian Mining Association of London He resigned in 1827, and returned to England via New York in company with Richard Trevithick, whom he had met in a penniless condition at Cartagena Stephenson then undertook the management of his father's factory in Newcastle, and assisted in the improvement of the locomotive. His work extended to Sweden, Denmark, Belgium, Switzerland and Egypt. He specialised in the construction of railway bridges. especially those of the tubular girder type, and among his more notable examples are the Royal Border bridge at Berwick-on-Tweed, the High Level bridge at Newcastle-on-Tyne, the Britannia tubular bridge over the Menai Straits, the Conway tubular bridge, and the Victoria tubular bridge over the St. Lawrence at Montreal. In 1847 he entered the House of Commons as member for Whitby, retaining the seat till his death in London on Oct. 12, 1859 He was buried in Westminster Abbey. London on Cet. 12, 1859. He was butten in westerniser Probest. See The Story of the Life of George Stephenson, including a Memoir of his Son Robert Stephenson, by Samuel Smiles (1857; new ed. 1881); jeaffreson, Life of Robert Stephenson (2 vols., 1864); and Smiles's Lives of the Engineers, vol. v. (1873).

STEPNEY, an eastern metropolitan borough of London, England, bounded north by Bethnal Green, east by Poplar, south by the river Thames, and west by the City of London and Shoreditch. Pop. (est. 1938) 200,500; area, 2.75 sq mi. The thoroughfares of Mile End Road and Whitechapel Road and that of Commercial Road East traverse the borough from the east and converge near the City boundary, where stood the ancient Aldgate. In the north Stepney includes the districts of Spitalfields, Whitechapel and Mile End (where William Booth commenced the work of the Salvation Army, July 1868); and in the south Wapping, Shadwell, Ratcliff and Limehouse. The name appears in Domesday and later as Stevenhethe. The suffix is thus the common form hythe, a haven: but for the prefix no certain derivation is offered. At Mile End, so called from its distance from the City (Aldgate), Wat Tyler and Richard II met in 1381. The district of Spitalfields has an old association with the silk-weaving industry; a trade in singing birds is also characteristic of this district. Wharves and factories line the river bank. In the extreme west the borough includes within its bounds the historic Tower of London  $(q,v_*)$ , the Royal Mint and the Tower Bridge over the Thames, Stepney is a bishopric suffragan in the diocese of London. The metropolitan borough of Stepney returns three members to Parliament, one each for the Limehouse, Mile End and Whitechapel and St. George's divisions.

STEPNIAK, SERGIUS (1852-1895), Russian revolutionist, whose real name was Sergius Michaelovich Kraychinski, was born in South Russia, of noble parents. He became an officer in the artillery; but his sympathy with the peasants, among whom he had lived during his boyhood in the country, developed in him at first democratic and, later, revolutionary opinions. He began secretly to sow the sentiments of democracy among the peasants His teaching did not long remain a secret, and in 1874 he was arrested. He succeeded in making his escape—possibly he was permitted to escape on account of his youth—and immediately began a more vigorous campaign against autocracy. His sympathetic nature was revolted by the brutal methods adopted towards prisoners, especially political prisoners, and by the stern measures of repression of revolutionary sentiment. For a time he supported a terrorist policy, and in 1880 he was obliged to leave the country. He settled for a short time in Switzerland, and after a few years came to London. He was already known in England by his book Underground Russia, which had been published in London in 1882. He followed it up with other works on the condition of the Russian peasantry, on Nihilism, and on the conditions of life in Russia. Stepniak was killed by a railway engine at a level crossing at Bedford Park, Chiswick, on Dec 23, 1805.

STEPPE, the level treeless Russian plains and thence sometimes extended as a type-name for similar plains elsewhere;

specifically it is usually applied to the plains in the south and south-east of European Russia and in the south-west of Asaatic Russia, and in this connection the term connotes level grassy areas on which the slight summer rainfall with a winter deficiency

produces patches with semi-desert conditions. STERCORARIDAE: see Skua.

STEREOBATE, in architecture, the rough masonry substructure, or foundation, of a Greek temple.

STEREOCHEMISTRY. The term stereochemistry (Greek STEREOCHEMISTRY). The term stereochemistry (Greek Stell, et demants) is applied in a wide sense to all thereos so that the stereochemical compounds which are believed to be due to the relative positions of the different atoms within a single molecule, or to the relative positions of different molecules in a larger aggregate of material. In this article, however, the term is used in a narrower sense. The following discussion is almost entirely limited to such aspects of the subject as are included in the field of stereochemical properties of individual molecules or ions. (For other aspects of the subject, which are largely ignored here, see X-RAY AND CRYSTAL STRUCTURE; ELECTRON DIFFRACTION; SPECTRO-SCOPY)

important goal of the structural theory of organic chemistry (knowledgy of which is here assumed, see Christian Combistry (knowledgy of which is here assumed, see Christian Combistry (knowledgy of the Christian Combistry) (knowledgy of the Christian Christ

In more mathematical language, a structural formula gives only the topological relations of the atoms within the molecule or ion to which it refers

About the middle of the 19th century, it was discovered that in certain instances the methods of structural chemistry led to the assignment of the same structural (topological) formula to more than one compound. It was, therefore, evident that the rules of structural chemistry were, in these instances, insufficient for the complete identification of the compounds in question, The theories of stereochemistry (in the narrower sense) were devised as the corrections necessary to remedy this defect. It proved possible to account for the number of distinct compounds to be associated with each structural diagram if the assumption was made that two molecules of the same substance must have not only the same structure, but also the same arrangement of their atoms in space. This geometrical interpretation has received independent support from the data derived from studies of X-ray and electron diffraction and of spectra. Consequently, although the possibility of an alternative, nongeometrical explanation of the observed numbers of isomers by 1946 seemed never to have been seriously explored, the correctness of the geometrical interpretation was generally accepted without question. In the present article, it is assumed explicitly.

For the sake of definiteness, but at the expense of anticipating and duplicating a small part of the discussion in subsequent sections, a specific example may be given here of the way in which stereoisomers are considered to differ geometrically. The two different 1, a-dichlorocthylenes, which possess the same structure CHCI=CHCI, are thought to have the different geometrical forms represented by the planar diagrams I and II.

### EARLY HISTORY OF STEREOCHEMISTRY

Optical Activity—The original approach to the subject of stereochemstry arose from a study of certain optical phenomena In 1868, E. J. Malus discovered the polarization of high by reflection (see Lioutr), and three years later D F Arago discovered the fact that crystals of quarts are optically active (i.e., that they rotate the plane of polarization of plane polarized high). That this optical activity (or rotatory power) is not restricted to crystalline solids was demonstrated by J. B Biot, who found in 1817 that of of turpentine and acqueous solutions of tartaric and or of sugar are optically active, and in 1817 that even gaseous tumpenture is also active.

Specific Rotation.—For the characterization of an optically active substance, the so-called specific rotation (introduced by Biotin 1836) has proved useful This quantity is defined by the equation

$$[\alpha]_{\lambda}^{t} = \frac{\alpha}{tJ}$$

where  $[\alpha_i]_i^k$  is the specific rotation for light of wave length  $\lambda$  at the temperature  $P^2$ ; and  $\alpha$  is the degrees of rotation produced by passage of the light through a tube l decemetres in length, which is filled with the optically active substance (either pure or in soliton) at a concentration of d grams per cubic centimetre. The rotation is taken with the positive sign if it is to the right  $(x_0, x_0)$  in the sense which is clockwase when regarded in the direction contrary to that in which the light is travelling), and with the negative sign if it is to the left (i.e., in the opposite, counter-clockwase sense.

Ideally, the specific rotation, as so defined, should be a characteristic property of the substance to which it applies, and its value should be independent of the experimental conditions. In practice, however, it varies somewhat in magnitude with the wave length of the light, with the temperature, with the solvent (if any) and with the concentration. In a few matances, even the sign of rotation is found to change with conditions. Thus, the substance of structure III (ethyl propoliturates) has a positive

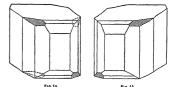

rotation if light of wave length less than about 4,909×Xr $^{\circ}$  cm. is used, but a negative rotation if light of wave length greater than about  $5,165 \times 10^{\circ}$  cm. is used material, aspartia acid, HO4C–CH<sub>T</sub>-CH(MH<sub>3</sub>)-CO<sub>5</sub>, has a positive rotation at  $20^{\circ}$  C. but a negative one at  $90^{\circ}$  C; the tartarn acid, HO4C–CHH-CHOH-CO-CO-H, which has a positive rotation in aquicous solution (see below) has a negative one in the crystalline form and also in a solution in a solution of the constant of the crystalline form and also in the control of the control of the control of the crystalline form and also as the control of the crystalline form and also are solved by the control of the crystalline form and also are appeared to the crystalline form and also are length to the crystalline fill and also are le

With colourless compounds, the variation in specific rotation with the wave length of the light used is ordinarily small, but nevertheless great enough to make necessary the precise statement of the wave length. The remaining variations are usually counteracted by standardization of the experimental procedure to as great an extent as possible. Thus, unless statements are made to the contrary, specific rotations are considered to apply to room temperature and to dilute solutions in specified solvents. Within these limitations, specific rotations may be employed for the characterization, identification and even quantitative analysis of optically active substances.

The Work of Pasteur.—After the discoveries of polarized light and of optical activity, the next important advance toward the indeed a stereochemical theories was made by Louis Pasteur

in a series of investigations on tariance and racemic acids, carried out chiefy during the years 1840-51. These two acids not only have dentical chemical compositions but also possess the same structure HO\_C-CHOH-CHOH-COH. Yet they show certain marked differences in properties. For example, racemic acid smuch less soluble in water than tariaric acid and crystallizes with water of crystallization, whereas tartaric acid separates in anhydrous crystalls, the most remarkable difference between the two substances, however, is in their effect on plane polarized plant. Tartaric acid and its salts (the tartates) are optically active; more specifically, they are dextrootatory (ie, their aqueous solutions rotate the plane of polarization to the right), on the other hand, racemic acid and its salts (the tartemates) are optically mactive.

Pasteur's discoveries arose out of a crystallographic investigation of tartaria card. He observed that there was a certain lack of symmetry in the crystalline form of this substance of such a kind that the crystal was nonsuperposable on its mirror image. The crystal and its image thus differ in the same kind of way as the right and left hands. He prepared and examined 1 yo direct salts of tartaric acid and found that each of these showed a simplar lack of symmetry in its crystalline form. Thus fig. is a repre-

FROM STEWART, "STEERS CHEMISTRY" (LONGWARD GREEN ( CO.)
FIG. 1 — (A & B) ENANTIOMORPHOUS CRYSTALS OF SODIUM AMMONIUM
TARTBATE

sents the crystalline form of one of these salts, sodium ammonium tartrate. If the crystal possessed the full symmetry of the system to which it belongs, two faces, corresponding with the two shaded areas, should be found in the positions indicated by broken lines. These faces, instead of occurring eight times in the crystal, occur only four times (there are of course two corresponding faces on the back of the crystal not shown in the figure); such faces, occurring only half as frequently as the full symmetry of the crystal demands, are termed hemihedral faces, The sodium ammonium tartrate crystal, on account of the presence of these hemshedral faces, is evidently nonsuperposable on its mirror image represented in fig 1b. In contrast to tartaric acid and the tartrates, racemic acid and such of its salts as Pasteur examined (with the exception of sodium ammonium racemate, see below) crystallize in symmetrical forms superposable on their mirror images. The optically active tartrates thus crystallize in dissymmetric forms, whereas the optically inactive racemates yield symmetrical crystals. (According to accepted terminology, an object is said to be dissymmetric if it is not superposable on its mirror image, and to be asymmetric if it possesses no element of symmetry whatever, see below. In discussions of stereochemistry, the word asymmetric is often used loosely in places where dissymmetric is intended; in the present article, however, the distinction is observed.)

Pasteur's chief discovery was made through investigating the exceptional racemate, sofium ammonum racemate, referred to above. Crystallized from water at a temperature below, 28° C., this sait yields crystals which, unlike those of the other necessate, yethic hemithedral faces; the crystals, however, are of two kinds. Some are identical in form with those of dextrootsarby sodium ammonium tartest (fg. 1a) and are in fact crystals of that sait. The other crystals differ from these only in that their hemithedrism is in the opposite sense; they are thus the

have the form represented in fig. 1b When picked out from the mixture and dissolved in water, they give a laevorotatory solution (i.e., a solution which rotates the plane of polarization to the left) The acid obtained from these crystals has a crystalline form which is the murror image of that of tartaric acid, and its solutions are laevorotatory. It is to be regarded as a second variety of tartaric acid

This new form of tartaric acid and the original one have exactly the same melting point and specific gravity, moreover, they exhibit exactly the same chemical reactivities toward all ontically inactive reagents. Two substances related in this manner are said to be enantiomorphs of each other. (The further expressions antimers and optical antipodes are also frequently used ) A more detailed discussion of the ways in which such pairs of substances resemble each other, and of those m which they differ from each other, is given below (see Enantiomorphs).

On the basis of his discoveries, Pasteur postulated that, in consequence of the arrangement of their constituent atoms in space. the individual molecules of any optically active substance must be nonsuperposable on their own mirror images (i.e., that they must be dissymmetric). Moreover, he postulated further that the molecules of any optically active substance must be superposable on the mirror images of the molecules of the enantiomorph of that substance. The situation visualized by Pasteur can be made more concrete with the aid of a rough analogy. The molecules of, say, dextrorotatory tartaric acid may be compared with righthand gloves, whereas those of its laevorotatory enantiomorph may be compared with left-hand gloves. No glove is identical with its own mirror image, but any right-hand glove is identical with the mirror image of any left-hand glove, and vice-versa. If the analogy is carried a step further, a crystal of racemic acid can be compared with a large package of pairs of gloves; since each pair consists of one right-hand and one left-hand glove, the package as a whole may be considered superposable on its mirror image These postulates of Pasteur form the basis of the following discussion; their justification lies in the fact that, as is shown below, they permit uniformly correct predictions to be made regarding the properties of, and relationships among, optically active substances.

### GENERAL DISCUSSION OF STEREOISOMERISM

The Symmetry Elements of Molecules,-It is desirable at this point to examine the characteristics of a molecule which make it dissymmetric, or prevent its being so, as the case may be.

The symmetry of any rigid body can be described with the aid of its so-called symmetry elements. These elements are of several different kinds, of which only the following need be mentioned here (1) An object is said to possess a plane of symmetry if a plane mirror can be imagined passing through it so that one-half of the object coincides with the reflection in the mirror of the other half. The plane of the mirror is then the plane of symmetry. (2) An object is said to possess an n-fold axis (or an axis of order n) if it possesses an axis, about which rotation by 360°/n brings the object into a position indistinguishable from its original one. The order n can take on any positive integral value, or it may be infinite if the object has, for example, the symmetry of a right circular cylinder. In general, n rotations by 360°/n bring the object into a position identical with, and not merely indistinguishable from, the original one. Any straight line passing through any object is clearly a one-fold axis; such one-fold axes may usually be ignored, however, in discussions of symmetry since an infinite number of them are always present. (3) An object is said to possess a centre of inversion (or of symmetry, or of reflection) if it contains a point within it, such that any straight line through that point encounters exactly the same environment in each of its two directions. Further discussion, with examples, of each of these types of symmetry element is given in the article CRYSTALLOGRAPHY. A number of additional examples are also mentioned below.

The above-mentioned plane and centre of symmetry are examples of elements with what may be termed reflection sym-

realization of the mirror image of sodium ammonium tartrate and metry. The most general type of element possessing this kind of symmetry is the so-called alternating (or mirror) axis, of which the plane and centre of symmetry are only special cases. Although no detailed description of alternating axes need be given here, mention should be made of the fact that an object may possess such an axis without having either plane or centre of symmetry.

Mathematical analysis has shown that an object is superposable on its mirror image if, and only if, it possesses reflection symmetry of some sort. In stereochemistry, this rule finds its only important applications in those instances in which the molecules have either planes or centres of symmetry, or both. No example had by 1946 been reported of an optically mactive substance, the molecules of which possess neither of these two symmetry elements. There is no theoretical reason why such a substance could not be prepared; it just happens that no chemist had by 1046 taken the trouble to do so. For this reason, the statement is often made that a compound must be optically active unless it is a mixture of enantiomorphs (like racemic acid) or else its molecules possess either planes or centres of symmetry. In practice, this simpler but incomplete form of the rule is adequate for most purposes. It is especially to be noted that the presence of simple (not alternating) axes of symmetry is not sufficient to ensure optical mactivity, or, in other words, that a molecule may possess an axis of symmetry and still be dissymmetric (For an example of a dissymmetric molecule with both twofold and threefold simple axes, see the cobalt compound XXXIX in the section below. Elements of Co-Ordination Number 6.

Enantiomorphs.—Since enantiomorphs have not only identical structures but also very similar configurations (s.e., atomic arrangements in space), the conclusion can be drawn that such pairs of substances should possess extremely similar properties. Indeed, in consequence of the mirror-mage relationship assumed to exit between enantiomorphs, the more precise conclusion can be drawn that each property of either enantiomorph must be (in the sense discussed below) the mirror image of the corresponding property of the other enantiomorph; or, in other words, that two enantiomorphs must be identical with respect to all those properties which are themselves (in this same sense) identical with their own mirror images, and can differ with respect to only those other properties which are different from their mirror images. For example, the melting point of any substance may be considered identical with its own mirror image, since the temperature at which solid and pure liquid are in equilibrium must be the same whether the experiment is viewed directly or by reflection in a mirror. Consequently, two enantiomorphs must have identical melting points. In a similar way, it can be shown that two enantiomorphs must have also identical vapour tensions at any specified temperature, identical boiling points at any specified pressure, identical densities under the same conditions, identical solubilities in any specified optically inactive solvent, identical rates of reaction with any specified optically mactive reagent (or reagents), identical equilibria in their reactions with any specified optically inactive reagent (or reagents), and so on. On the other hand, the mirror image of a rotation of the plane of polarization by a specified number of degrees to the right (or left) may be considered to be a rotation by exactly the same number of degrees to the left (or right), respectively. Consequently, two enantiomorphs, under identical conditions, must rotate the plane of polarization by equal amounts but in opposite directions. Similarly, the mirror image of right (or left) circularly polarized light is identical not with itself but instead with left (or right) circularly polarized light. Consequently, two enantiomorphs may be expected to possess different optical properties (e.g., absorption spectra, indexes of refraction, etc) when examined with circularly polarized light, but not when examined with ordinary light or even (except for the optical rotation) when examined with plane polarized light; conversely, the optical properties of a single optically active substance may be expected to be different with right and left circularly polarized light. The expected differences in spectrum have been observed experimentally (circular dichroism, Cotton effect); and the differences in index of re-fraction, although so small that their direct observation is diffi-

cult, are known always to exist since the observed angle of rota- pens that a set of stereoisomers contains both optically active and tion by an optically active substance can be shown to be proportional to the difference in the indexes of refraction for right and left circularly polarized light Moreover, since an optically active solvent is not identical with its mirror image, the solubilities of two enantiomorphs in such a solvent need not be the same, differences of this sort are found in practice, however, to be too small to be observed. On the other hand, measurable differences have been found in the rates and extents of adsorption (q,v) of enantiomorphs upon optically active solid adsorbents, and in the rates and equilibria of their reactions with optically active reagents (see Asymmetric Syntheses and Decompositions, below) Finally, the crystals of two enantiomorphs may be nonsuperposable mirror images of each other (cf. the enantiomorphic tartaric acids and tartrates, above); in many instances, however, the forms of the crystals of enantiomorphs are symmetrical and ıdentıcal

Diastereomers.-Examples of stereoisomers which are not enantiomorphs of each other are well known. In 1853 Pasteur discovered that the cinchonine (see Cinchona Bark, Alkaloms or) salt of either tartaric or racemic acid, when heated for sevor) sait of entire catalities account and matter as a certain out at 170° C, is transformed into the sait of still a different stereoisomeric acid. This acid, known as meso tartaic acid, resembles racemic acid in being optically inactive, but it differs from racemic acid in having a different melting point, different solubilities, etc., and also in not being separable into two enantio-morphic forms. The individual molecules of meso tartaric acid, therefore, must be symmetrical (se., superposable on their mirror images) The substance, although a stereoisomer, is not an enantiomorph, of either of the active tartaric acids.

In subsequent years, a large number of nonenantiomorphic stereoisomers have been discovered. An extreme example of this is provided by the aldohexoses (see Carbonydrates), of which the pyranose structure permits no less than 32 stereoisomeric forms, divisible into 16 pairs of enantiomorphs, all are known.

No general term had by 1946 been universally adopted for the description of the relationship between two stereoisomers which are not enantiomorphs of each other. The word "diastereomer" (or diastereoisomer, or diamer) is often applied to certain, but usually not to all, such pairs of substances. Thus, dextrorotatory tartaric acid and meso tartaric acid are considered diastereomers of each other, as are also any nonenantiomorphic 2 of the 32 aldohexoses; but fumaric and maleic acids are not usually considered diastereomeric. The reason for this distinction is that the isomerism of the tartaric acids and of the aldohexoses is of the type known as optical, whereas that of fumaric and maleic acids is of the type known as geometrical; most commonly, two nonenantiomorphic stereoisomers are said to be diastereomers of each other only if they are optical isomers, and not if they are geo-metrical isomers. The distinction between these two kinds of stereoisomerism is discussed briefly below in the section Optical and Geometrical Isomerism; here, it may be mentioned only that this distinction is not at all sharp since many pairs of substances are both optical and geometrical isomers at the same time. For this reason, and also for purposes of brevity and convenience, the word "diastereomer" is used throughout the remainder of this article to designate any nonenantiomorphic stereoisomer. Thus, even fumaric and maleic acids are said to be diastereomers of each other. It is to be noted, however, that, in this respect, the present article departs somewhat from the most customary terminology.

Unlike enantiomorphs, diastereomers (in the broad sense just defined) need not have closely similar physical and chemical properties. Indeed, they may differ as greatly as do structural isomers. For example, either of the optically active tartaric acids melts at 187° C., whereas meso tartaric acid melts at 143° C.; maleic acid melts at 130.5° C. and loses water at 160° C. to form an anhydride, whereas fumaric acid melts at 287° C and forms no anhydride (under sufficiently vigorous conditions, however, fumaric acid is transformed into the anhydride of maleic acid);

Meso Forms. As with the tartaric acids, it frequently hap-

optically mactive members. The mactive members of such sets are frequently distinguished from their active isomers by being called meso forms (This is, of course, the significance of the name "meso tartatic acid.") Meso forms are often referred to as internally compensated, since their individual molecules can be divided (in thought) into two halves, each of which is dissymmetric and the mirror image of the other half, the rotatory powers of these two halves exactly cancel each other, so that the entire molecule is inactive

Racemic Modifications.-- A mixture of equal quantities of two enantiomorphs, which is of course optically inactive, is known as a racemic modification. The name is derived from racemic acid, the first example of such a mixture to be carefully studied (This double use of the word "racemic" is found in practice to lead to httle if any confusion ) A racemic modification is sometimes said to be externally compensated (cf. the internally compensated meso forms). Any process by which an optically active substance is transformed into the corresponding racemic modification is known as a racemization, conversely, any process by which a racemic modification is separated into the two enantiomorphs is known as a resolution. (See Racemization and Resolution, below.)

In the liquid and gaseous states, a racemic modification seems always to be merely a mechanical mixture of its two components. In the solid state, however, three different situations have been encountered (1) Sometimes, as with sodium ammonium racemate crystallized from water at a temperature below 28° C. (see above), the solid is a conglomerate (or racemic mixture) consisting of separate crystals of the two enantiomorphic forms (2) Sometimes, as with the dimethyl ester (see ESTERS) of racemic acid, the two enantiomorphs form a 1.1 compound (or racemate) with each other. Such compounds, however, decompose into their constituents at temperatures above their melting points. (3) Sometimes, as with camphor oxime (see CAMPHORS; OXIMES), the enantiomorphs form a solid solution (q v.) (or pseudoracemic mixed crystal).

Occasionally the racemic modification is spoken of as a definite substance, as if it were distinguishable from the enantiomorphs of which it is composed Thus, the statement is sometimes encountered that there are altogether four stereoisomeric tartaric acids, viz., the dextro- and laevorotatory forms, the meso form and racemic acid. Such a mode of description is, however, not really correct. If the racemic modification is a compound, it has a greater molecular weight than the pure enantiomorphs, and so it is not strictly an isomer of them at all; on the other hand, if it is not a compound, then it is not a pure substance but a mixture of two substances, and so again it is not strictly an isomer of the enantiomorphs. In this article, the racemic modification is treated as a mixture and not as an additional stereoisomeric

A Word About Nomenclature.-Dextrorotatory and laevorotatory enantiomorphs were originally designated by the prefixes d and l, respectively, so that the dextrorotatory and laevorotatory tartaric acids, for example, were called d-tartaric acid and Ltartaric acid, respectively. Somewhat later, however, these prefixes were made to refer also to the so-called optically active series to which the substances belonged, as well as to the directions of rotation. (For the significance of these series, see Optically Active Series, below.) As a result of this ambiguity in nomenclature, many substances were found which had to be assigned the prefix d because they were dextrorotatory, and, at the same time, the prefix I because they belonged to the I-series (or vice versa). The confusion which was thus caused has been alleviated to some extent by the adoption of the convention that the prefixes d and l (or frequently D and L) refer only to the optically active series, and that the further prefixes (+) and (-) be employed to represent dextrorotation and laevorotation, respectively. Thus, the complete names of the two optically active tartaric acids are d(+)-tartaric acid and l(-)-tartaric acid, since the dextrorotatory and laevorotatory forms have been found to belong to the d- and l-series respectively. In this instance, the direction of rotation and the series coincide, in other instances, however, they do not do so, as with d(-)-lactic acid and its enantiomorph 1(+)-lactic acid, of structure CH3-CHOH-CO2H

Unfortunately, the convention just discussed is not always followed consistently by all chemists. If a substance does not belong to any of the accepted optically active series, the prefixes d and I are often used, as originally, to indicate the direction of rotation Thus, the naturally occurring laevorotatory quinine (q v.) is often referred to as l-quinine rather than as (-)-quinine. No confusion can arise in such instances since no d- and l-series have been defined for alkaloids like quinine However, an expression like "d-lactic acid" may refer either to the dextrorotatory form, which belongs to the l-series (see above), or to its enantiomorph in the d-series. Consequently, such an expression is configurationally meaningless, unless accompanied by a statement as to which convention is being employed. In this article, the prefixes d and l are used to represent only the optically active series, and the prefixes (+) and (-) are used always to represent the direction of rotation (even for substances like quinine, for which no series have been defined).

Optically inactive meso forms are frequently designated by the prefix i (for inactive) or m (for meso) Thus mesotartaric acid may be called either i-tartaric acid or m-tartaric acid Racemic modifications are similarly designated by the prefix r (for racemic) or dl (to indicate that the compound is a mixture of the two enantiomorphs). Thus, racemic acid may be called either r-tartaric acid or di-tartaric acid.

Racemization.-The ease with which an optically active substance can be transformed into the racemic modification varies within wide limits. On the one hand, the racemization of certain compounds (for example, an optically active paraffin hydrocarbon) is so difficult that no method is known by which it can be achieved at all; but, on the other hand, the racemization of certain other compounds (for example, a tertiary amine, see Stereochemistry of Nitrogen, below) is so easily accomplished that the optically active forms cannot even be obtained. Innumerable further compounds exist, however, with which the ease of racemization lies between these two extremes.

Such compounds can be separated (see Resolution) into the active enantiomorphs, which can then be racemized more or less readily.

The experimental conditions under which the racemization of racemizable substances can be effected also vary widely. In all instances, however, the racemization is presumed to occur as a result of a reversible transformation into an unstable substance of such nature that it is necessarily symmetric and so incapable of optical activity; the reverse transformation back from this hypothetical inactive intermediate then leads to the inactive (i.e., racemic) modification of the original substance.

The transformations which thus lead to racemization are considered most commonly to involve chemical reactions of familiar type, but occasionally to involve merely geometrical deformations.

The interconversion of diastereomers is closely analogous to the racemization of optically active substances; accordingly, the ways in which such transformations can be brought about, and the mechanisms by which they are presumed to occur, require no further discussion here.

Resolution .- Whenever a substance capable of optical activity is prepared under the usual experimental conditions from exclusively inactive reagents, the product obtained is always the inactive racemic modification. This is because, in view of the complete symmetry of the experimental situation, the probability that a molecule of the dextrorotatory enantiomorph will be formed is exactly the same as the probability that one of the laevorota-tory enantiomorph will be formed. Consequently, equal numbers of molecules of the enantiomorphs must be formed, so that the product must be recent. It an optically active product is desired instead, therefore, a recently english performed, so that the product must be recent. It an optically active product is desired instead, therefore, a recently englished be performed.

\*\*All a separation of a racemic modification into its two optically educated as in a particular product in the control of anatomorphis in apartic all their properties. A separation by grantiomorphis in apartic all their properties.

crystallization, for example, is impossible, because enantiomorphs have identical solubilities in all inactive solvents and also (within the limits of measurement) in all active solvents as well. A separation by fractional distillation is likewise impossible because enantiomorphs have identical boiling points at all pressures, and identical vapour tensions at all temperatures. In a small number of cases, however, partial separations have been effected by fractional adsorption on an optically active adsorbent.

Two important methods of resolution were developed by Pasteur. The first of these, known as the method of spontaneous separation, has already been described in connection with Pasteur's work on sodium ammonium racemate. It can be employed if the solid racemic modification is a conglomerate composed of observably different crystals. Only about a dozen instances in which this condition is satisfied have been reported in the organic chemical literature. Consequently, this method, although of great

historical and theoretical interest, is seldom applicable Pasteur's second method of resolution is of much greater generality than his first, and it is the only one commonly used. It is based upon the transformation of the mixture of enantiomorphs into a mixture of diastereomers, which, since they differ in physical properties, can be separated relatively easily This transformation requires the use of some previously obtained optically active substance. For example, Pasteur showed in 1853 that when racemic acid is treated with a naturally occurring optically active base, such as cinchonine, strychnine, brucine or quinine (see ALKALOIDS), the resulting salt is a mixture of diastereomers and no longer one of enantiomorphs. This is because (if, for definiteness, the base is assumed to be dextrorotatory) the salt formed from the (+)-acid and (+)-base is not the mirror image of the one formed from the (-)-acid and the same (+)-base. (The mirror image would instead be the salt formed from the (-)-acid and (-)-base.) The two salts present in the mixture may, therefore, be expected to have different solubilities and so to be separable by crystallization. After the separation has been carried out, the salt from the (+)-acid and (+)-base gives the pure (+)-acid when treated with a strong mineral acid, and the other salt gives the pure (-)-acid when treated similarly.

In the form just outlined, Pasteur's second method can be applied to the resolution of only racemic acids. Various modifications have been developed, however, which permit it to be greatly extended. Thus, a racemic base can be resolved by means of salt formation with an optically active acid, a racemic aldehyde or ketone can be resolved by means of hydrazone formation with an optically active hydrazine, and so on. Moreover, a racemic alcohol can be resolved if it is first transformed into the acid ester of a dibasic acid (such as phthalic acid, q.v), which is neutralized as before with an optically active base; the resulting ester salt can then be separated into the diastereomeric forms and finally hydrolyzed back to the alcohol.

Similar schemes of greater or less complexity can be devised for most remaining types of substance.

Asymmetric Syntheses and Decompositions.-If a compound capable of optical activity is prepared in a dissymmetric environment, the product obtained need not be completely racemic since factors are present which may favour the formation of one enantiomorph over that of the other. Such reactions are known as asymmetric syntheses (although dissymmetric syntheses might seem a more appropriate expression). For example, although the reduction of inactive phenylglyoxylic acid C<sub>6</sub>H<sub>3</sub>-CO-CO<sub>2</sub>H leads to completely racemic mandelic acid CoHo-CHOH-COoH, the reduction of the (-)-menthyl ester of the acid, followed by hydrolysis of the resulting menthyl mandelate gives a mandelic acid which is laevorotatory although it contains a considerable amount of the (+)-enantiomorph. This slightly active acid can be separated by crystallization into the "optically pure" (-)-mandelic acid and r-mandelic acid. A different type of asymmetric synthesis is illustrated by the base-catalyzed reaction between benzaldehyde C<sub>6</sub>H<sub>5</sub>-CHO and hydrogen cyanide HCN to give mandelonitrile C<sub>6</sub>H<sub>5</sub>-CHOH-CN. Since the reagents are optically inactive, the product is necessarily racemic if the basic catalyst is also inactive; however, if an optically active catalyst, such as

the alkaloid quinine, is used instead, the resulting mandelonitrile conceivably have started at such a time and place that the first is somewhat optically active

The asymmetric syntheses mentioned above are relatine, succee they require the previous existence of at least one optically active substance. A few absolute asymmetric syntheses, which are subject to this requirement, have been reported. These synthese are based upon photochemical reactions (see Photocutsateriv) initiated by circularly polarized light, since circularly polarized light is not identical with its own mirror image (see above), at the provides the necessary dissymmetric environment.

"Asymmetric" decompositions, either relative or absolute, can be performed under conditions analogous to those employed with the above asymmetric syntheses

Asymmetric syntheses and decompositions are of especially great importance in biological reactions, since the reactions which occur in living systems are so frequently brought about by optically active reagents or are catalyzed by optically active catalysts (enzymes) For example, the fact that green plants are able to transform mactive water and carbon dioxide into active carbohydrates (see Photosynthesis) is due to the occurrence of asymmetric syntheses. Similarly, the fact that the natural d(+)glucose (q v ) is easily digested by animals and is fermented by yeast, whereas its enantiomorph undergoes neither reaction, must be attributed to the occurrence of asymmetric decompositions An important application of such biological reactions was discovered by Pasteut, who found (1856-60) that the mould Pemcillum glaucum, when allowed to grow in the presence of racemic (tartaric) acid, destroys the (+)-enantiomorph preferentially, so that the acid which remains becomes laevorotatory This method of obtaining optically active substances is of considerable generality since other micro-organisms have been found to have similar effects, and since other racemic modifications have been found to be made active in similar ways; it has, however, serious limitations since many substances are not attacked by any known organisms, and since often the organism destroys just the enantiomorph which is desired. It should be noted that the method cannot be called a resolution since one of the two enantiomorphs is always destroyed. The Origin of Optically Active Substances in Nature .-

The frequent occurrence of optically active substances in animal and vegetable sources can be explained only as the result of asymmetric syntheses or decompositions. These reactions are made possible by the presence of pre-existing optically active substances, which must themselves have been made by asymmetric syntheses or decompositions; and so on. If life started on this earth many millions of years ago by the coming together of simple inorganic and optically inactive materials, there must have been a time at which the optical activity began. The question therefore arises how it came into being in the absence of any pre-existing optically active substance. (If life is assumed not to have started on this planet but to have come-from some other body, the difficulty is merely pushed back in time and not avoided!) Naturally, the answer to this question is unknown, and possibly unknowable. Scientists have nevertheless sociulated about if for many vears.

Two types of theory have been advanced to explain the origin of optical activity. The first of these is based upon the fact of spontaneous separation. It is not inconceivable that an optically active substance produced in small amount in this way may have been involved somehow in the origin of life. Thus, an early form of life may have happened to consume some d-th-y-sodium armonium tartrate, or to have lived on the surface of a crystal of (--)-quartz for this explanation is that it depends too much upon the operation of chance. There would on the average be just as much ((-)-a soft d'+)-sodium ammonium tartrate for the organism to consume, and just as many crystals of (-t)-a soft (-)-quartz for it to live on; the supposition that the universal and uniform occurrence of optical activity could have arise in such a manner seems unlikely a calcivity could have arise in such a manner seems unlikely as

The second kind of theory is based upon the existence of absolute; asymmetric syntheses and decompositions. For example, since light can be circularly polarized by reflection, life may

conceivably have started at such a time and place that the first organisms were more or less constantly subjected to the action of either right or left circularly polarized light. This theory avoids the difficulty of assigning too great a role to chance. It encounters a different one, however, in that the activities producible photochemically in the laboratory have always been extremely small, and also in that the natural circular polarization of light could at most be slight. A further theory, which assumes that the earth's magnetic held produced the necessary dissymmetric environment enjoys a similar advantage, but it suffers from similar disadvantages.

#### THE STEREOCHEMISTRY OF CARBON

The Tetrahedral Carbon Atom.—The above extremely general considerations require no assumptions in regard to the actual geometrical forms of the molecules under discussion. Such assumptions become necessary, however, if the attempt is made to account for the numbers of stereosomers corresponding to each structural formula. The first successful theory based upon explicit geometrical assumptions was brought forth simultaneously and independently in 1874 by J. H. van't Hoff and J. A. E. Bel. The ideas of van't Hoff were somewhat more definite than those of Le Bel, but they differed in no respect important to the present article. The following discussion makes no effort to follow either van't Hoff's or Le Bel's development very closely; it attempts instead to present the fundamental principles in logical rather than in historical order.

For the molecular formula CH4, only the single structure I can be drawn (if, as usual, carbon and hydrogen are considered to be quadrivalent and univalent, respectively), and only the

single substance, methane, is known. Similarly, for the formula CH<sub>2</sub>Cl, only the single structure II can be drawn, and only the single substance, methyl chloride, is known. Now, if one hydrogen atom in methane were different from any one of the others in any respect, the substance produced by the replacement of the strik hydrogen atom by a chlorne atom should be different from the one produced by the replacement of the second hydrogen atom. Consequently, at least two distinct substances, CH<sub>2</sub>Cl, should exist. The fact that only one such substance is known strongly suggests, therefore, that all four hydrogen atoms of methane are completely equivalent to each other, not only structurally (i.e., beologically, see above), but also geometrically

Alternative interpretations of the existence of only one substance with the formula CH2Cl can be imagined. Thus, several different substances with this formula might be theoretically possible, but only one of these might be stable enough to be isolated; or the various substances might be too closely similar in all their properties to be separated or distinguished from each other, or additional isomers might be obtainable if only suitable methods of preparation could be discovered; and so on At one time, chemists made serious efforts to establish beyond question the complete equivalence of the four hydrogen atoms of methane. by replacing them systematically, and one at a time In this way, they hoped to prove that, no matter which hydrogen atom is replaced by a given substituent atom or group, the same product results. It is now recognized, however, that this work was without significance since there is no assurance that, in a replacement reaction, the entering atom or group occupies the same relative position in space as did the one which it replaces (see Walden Inversion, below). The most satisfactory evidence supporting the belief that all the hydrogen atoms of methane are equivalent is therefore the fact that, in spite of the tremendously large number of known organic compounds, no example has ever been encountered of more than one substance CH3R, where R is any specified atom or group. (Here, and throughout the remaining discussion, groups designated by general symbols like R. S. or the like are considered to be not sufficiently complex to permit somersm within themselves) Thus, there is only one CH-IC, as has already been mentioned, only one CH-IC, only one CH-IB, only one CH-II, only one CH-INO<sub>2</sub>, only one CH-CO-II, only one CH-ICIs, and so on almost without limit For this reason, no chemist now seriously considers the possibility of nonequivalent hydrogen atoms in methane.

The requirement that all four hydrogen atoms of methane be geometrically equivalent restricts the atomic arrangements to the following: (1) The hydrogen atoms might lie at the corners of a rectangle, with the carbon atom at the centre, as in III The dotted lines outliming the rectangle are given only for the sake of clarity; they do not represent valence bonds of any kind This model is known as the planar model (2) The hydrogen atoms might he at the corners of the base of a square pyramid, with the carbon atom at the anex, as in IV. (It should be noted that,

if the base of the pyramid were rectangular rather than square, two enantiomorphic forms of each monosubstituted derivative CH2R would be possible. Such a configuration can, therefore, be excluded ) The dotted lines are again given only for the sake of clarity. This model is known as the pyramidal model (3) The hydrogen atoms might lie at the corners of a tetrahedron, with the carbon atom in the centre, as in V. The dotted lines which outline the imaginary tetrahedron are given, as before, only for the sake of clarity. A more convenient, but equivalent, representation of this so-called tetrahedral model, which is employed throughout the remainder of the article, is shown in the diagram VI. The two broken lines in this latter figure represent valence bonds to hydrogen atoms lying behind the plane of the paper; the two heavy lines represent bonds to hydrogen atoms lying in front of the plane of the paper. The equivalence of the hydrogen atoms does not require that the tetrahedron be a regular one, just as, in the planar model, it does not require that the rectangle be a square; only certain, rather symmetrical types of tetrahedron are satisfactory, however.

The decision among the planar, pyramidal and tetrahedral models is made possible by a consideration of the numbers of isomeric substances CE<sub>0</sub>KS, where R and S represent any two specified, but not necessarily different, atoms or groups Only one known substance, methylene chloride, exists with the formula CH<sub>1</sub>Cl-CO<sub>2</sub>H, etc. For no formula of this type is more than a single substance known. Now, the planar model would lead to the three distinct spatial arrangements or configurations VII, VIII and Xi. of which VII and VIII are identical if the rectangle

is a square. Since IX cannot be identical with VII or VIII under any circumstances, however, this model requires the existence of at least two stereoisomeric forms and so can be excluded from further consideration.

The pyramidal model might be expected, like the square planar one, to permit two stereosomeric substances. Thus, the two configurations X and XX are possible. If R and S are not idenlical, however, the configuration XX is dissymmetric, and so its fromsuperpossible mirror mage '(canationorph) XII represents

still a thud stereoisomer Since stereoisomerism has never been observed with structures of the present type and, moreover, since optical activity has never been encountered, the inference can be drawn that the pyramidal model also is incorrect.

Only the tetrahedral model remants If the tetrahedran is regular, this model permits only a single substance CHARS, whether R and S are identical or different. In particular, the configuration, as shown in XIII, is symmetrical, since it has a plane of symmetry passing through R, S and C, and so no optical activity is possible and no enantiomorphs can exist. The regular tetrahedral model, therefore, reproduces the experimentally observed numbers of isomers. The irregular tetrahedral model, on the other hand, permits to many isomers and so can be excluded.

The regular tetrahedral model is, therefore, the only one in agreement with the observed numbers of isomers; consequently, it must be assumed to be correct. Confirmation of this model is provided by the fact that it correctly predicts the occurrence of optical activity, and hence also of enantiomorphs, with substances with the formula CPRST, where no two of the atoms or groups P, R, S and T are identical. Lactic acid, CHz-CHOH-CO-H, for example, occurs in enantiomorphic dextrootatory and laevorotatory forms. For the molecules of these substances, the nonsuper-posable, mirror-mange configurations XIV and XV are possible. One of these must therefore represent the molecule of the dextrortatory lactic acid, and the other must represent that of the laevorotatory form; however, there is no way at present of deciding with complete certainty which configuration belongs to each fing with complete certainty which configuration belongs to each

Physical evidence has confirmed the conclusions reached above Studies of spectra and of X-ray and electron diffraction have shown that a saturated carbon atom is indeed tetrahedral, in the sense that the four single bonds which it forms are directed toward the corners of a tetrahedron, of which it occupies the centre. (The tetrahedron itself, of course, is only an intellectual construction without physical reality.) Moreover, the tetrahedron has been found to be regular, or very nearly regular, so that the angle between any two of the single bonds formed by the central carbon atom has the so-called tetrahedral value of 109° 28', or very nearly that value. When the four atoms or groups joined to the carbon atom are of the same kind, as in methane CH4 or carbon tetrachloride CCl., the tetrahedron seems always to be strictly regular, but, when the atoms or groups are not of the same kind, as in methylene chloride, CH<sub>2</sub>Cl<sub>2</sub>, some small distortions may occur. Thus, in methane and carbon tetrachloride, each H-C-H and Cl-C-Cl bond angle, respectively, is exactly 100° 28'; but in methylene chloride, the Cl-C-Cl angle is found instead to be about 112°. The spreading of the angle here is presumably due to a greater repulsion between the relatively large chlorine atoms than either between the chlorine atoms and the much smaller hydrogen atoms or between the two hydrogen

As mentioned above, an irregular tetrahedral model would apparently allow the existence of a greater number of stereoisomers than is observed; nevertheless, it may be presumed that no small distortions of the type found in methylene chloride can

for by the perfectly regular model This is because the configurations belonging to any further stereoisomers would doubtless be unstable, so that the corresponding molecules would revert spontaneously and immediately to the stable configuration

Asymmetric Carbon Atoms,-A carbon atom is said to be asymmetric if it is joined to four different atoms or groups Thus, of the three carbon atoms in lactic acid, the central one is seen to be asymmetric (The terminology here is correct since an "asymmetric" carbon atom possesses no element of symmetry and so is actually asymmetric, and not merely dissymmetric The majority of all known optically active substances consist of molecules which contain one or more asymmetric carbon atoms However, the presence of such atoms is neither necessary nor sufficient for optical activity As will be discussed below, many substances containing no asymmetric atoms are active, and, conversely, many containing asymmetric atoms are inactive. Optical activity is caused by the dissymmetry of each individual molecule as a whole, the presence or absence of asymmetric atoms is important only in so far as it determines the symmetry or dissymmetry of the molecule

The Stereochemistry of Olefinic Compounds,-van't Hoff assumed that the carbon atoms in unsaturated compounds have the same tetrahedral form as those in the saturated substances The configuration of ethylene, H2C=CH2, thus becomes XVI. If this configuration is correct, the six atoms in the molecule lie in

the same plane (the plane of the paper in XVI), the H-C-H bond angles have the tetrahedral value of 100° 28′, the C-C-H angles (or, more precisely, the angles between the carbon-hydrogen bonds and a straight line passing through the carbon atoms) is 125° 16', and the carbon-carbon distance is 0 58 times that in ethane, CH3-CH3

Although erroneous in some respects (see below), van't Hoff's configuration of ethylene appears to be correct in all essential stereochemical details. In particular, it leads to correct predictions of the numbers of stereoisomeric forms of suitably substituted ethylenes Indeed, its significant features can be deduced directly, and without reference to the tetrahedral carbon atom, from considerations of isomer numbers. (As was true also in the above discussion of the saturated compounds, the assumption must be made here that all the theoretically possible stereoisomers corresponding to the structural formulae considered are known ) The fact that ethylene is the only known substance with the molecular formula C2H4 shows that the lines bisecting the two H-C-H angles must be along continuations of the line joining the carbon atoms; otherwise, at least two stereossomeric substances, with the configurations XVII and XVIII should be possible (For the sake of both simplicity and generality, the geometry of the two bonds constituting the double bond is not indicated here explicitly.) Moreover, the planes defined by the two CH2 groups must be either identical with, or at right angles to, each other,

since otherwise the molecule would be dissymmetric and the substance would be optically active. Finally, the decision between the planar and perpendicular models can be made by a consideration of the nature of the isomeric substances with the structure ments (or conformations) are consistent with the assumption of

give rise to a greater number of isomers than could be accounted CHR=CHR The planar model permits the two configurations XIX and XX, whereas the perpendicular model permits XXI

and XXII. Now, XIX and XX must represent optically inactive diastereomers since, with each, the plane of the molecule is a plane of symmetry; on the other hand, XXI and XXII must represent a pair of enantiomorphs since they are nonsuperposable mirror images of each other, with neither plane nor centre of symmetry. In the particular case in which R is the carboxyl group, CO2H, two substances, fumaric and maleic acids (qv), are known, each of these acids is optically mactive, and the two differ markedly in nearly all their properties (see above). Consequently, they must be diastereomers and cannot be enantiomorphs Since numeious further examples of similar type are known, and since optical activity has never been encountered in substances with the structure CHR = CHR (unless R represents a dissymmetric group), the necessary conclusion is that the planar model is correct, in agreement with van't Hoff. The configuration XIX is commonly said to be cis (Latin cas, on this side), whereas XX is said to be trans (Latin trans, across)

From considerations of isomer number alone, no information can be obtained regarding the values of the bond angles or of the interatomic distances in ethylene and its derivatives; consequently, the angles and distances derived from van't Hoff's configuration, with the tetrahedral carbon atoms, cannot be verified by purely chemical procedures Physical investigations (see Spec-TROSCOPY; X-RAYS AND CRYSTAL STRUCTURE; ELECTRON DIF-FRACTION) have shown, however, that it is precisely in such respects that van't Hoff's model is incorrect. Thus, in ethylene, the H-C-H and C-C-H angles are more nearly equal to 120° than to 109° 28' and 125° 16', respectively; and the carbon-carbon distance is more nearly o 87 than o 58 times that in ethane. Moreover, the modern quantum-mechanical picture of the double bond is rather different from that provided by the tetrahedral model XVI. Nevertheless, these defects in no way limit the usefulness of the simple model for the prediction and interpretation of the observed numbers of stereoisomers.

Stereochemistry of Acetylenic Compounds.- Just as with ethylene, van't Hoff assumed that the carbon atoms in acetylene. H-C-C-H, are tetrahedral. He accordingly wrote the configuration as XXIII. In agreement with this linear model, no stereoisomers, to which configurations like XXIV and XXV must be

$$H-C \bigoplus_{XXIII} C - H \quad C \equiv C \quad C \equiv C$$

assigned, have ever been encountered. (In XXIV and XXV, as in XVII and XVIII, the geometry of the bonds constituting the multiple bond is not indicated explicitly) Moreover, recent physical evidence supports the linear arrangement of the atoms. Consequently, although van't Hoff's model of acetylene is inaccurate in several respects (analogous to those in which his model of ethylene is inaccurate, see above), it leads always to correct predictions of the numbers of isomers.

Free Rotation.-Certain limitations must be imposed upon the general statement that two molecules correspond to different substances unless they are exactly alike with respect to the relative positions in space of all their atoms. For the structure H<sub>3</sub>C-CH<sub>2</sub>, for example, an infinite number of geometrical arrangetetrahedral carbon atoms, these include the two represented by XXVI and XXVII, as well as all the further ones obtainable from either XXVI or XXVII by rotation of one CH<sub>2</sub> group with

respect to the other about the carbon-earbon bond. If each of these conformations represented a distinct substance, then an infinite number of stereosomers with the structure in question should cast. Only a single substance, ethane, is known however Smilar considerations apply to nearly all further structures in which multivalent atoms are joined by single bonds. It is evident, therefore, that, if the geometrical interpretation of stereosomerism is to be maintained, some further assumption, which restricts the predicted numbers of somers, is required.

The assumption generally adopted for this purpose is contained in the rule that any two conformations (such as XXVI and XXVII, or any other two of the infinite number of possible ones) are to be considered equivalent if they differ only by the rotation of one or more parts of the molecule about one or more single bonds. Thus, XXVI, XXVII, etc. are equivalent; all these conformations correspond to the same substance, ethane, and all are said to represent the same configuration. Although this rule has a number of exceptions (see Optically Active Biphenyls, below), it is swiftently general to find application throughout the same of the same of the same configuration and the same of th

A common alternative statement of the above rule is that rotation about single bonds is free. The use of the term "free rotation" suggests that, in ethane for example, no forces operate to make any one conformation more stable than any other, so that each molecule of the substance spends equal fractions of its time in each of its possible geometrical arrangements. This interpretation is obviously consistent with the fact that stereoisomeric forms of ethane, differing by rotation about the carbon-carbon bond, do not occur; nevertheless, it is probably incorrect. From a combination of spectroscopic and thermochemical data, the conclusion has been drawn that the "eclipsed" conformation XXVI is less stable (ie., has a higher energy) than the "staggered" one XXVII by about 3,000 calories per mole. If this conclusion is correct, most of the molecules at any one time must have arrangements rather close to the staggered one XXVII. Stereoisomerism is still impossible, however, since each molecule must spend part of its time in each of the conformations, and since the transition from any one conformation to any other is rapid and easy.

In nearly all other substances for which data are available, the situation seems to be similar to that in ethane. Certain conformations seem always to be appreciably more stable than others differing from them by rotation about one or more single bonds, but stereoisomers are not encountered because the transition from one conformation to another is easy. In general, stereoisomers can be expected to occur only if there are two or more essentially different geometrical arrangements of the atoms, between which transitions are not easy. A transition may be considered easy at ordinary temperatures if it can be undergone by a molecule possessing an energy much less than about 20,000 calories per mole above the average. This is because, as a result of the statistical variations in energy (see KINETIC THEORY OF Marries), the number of molecules possessing the required excess energy is then sufficiently great to permit an appreciable rate of interconversion; consequently, the separation of the isomers clearly impossible in ethane, since a molecule of this substance requires an excess energy of only approximately 3,000 calories

per mole for a complete rotation of 360° about the carbon-carbon bond On the other hand, the existence of the stereosomener malerc and fumaric acids, to which the configurations XXVII and XXIX, respectively, have been assigned, shows that only such molecules a sposses at least 20,000 caltors per mole of excess

energy can undergo the transition; or, in other words, that the energy of the perpendicular arrangement XXX (or of its enantiomorph, cf. XXI and XXII) must be at least 20,000 calories per mole higher than that of either XXVIII or XXIIX Just as the nonexistence of stereosomers in ethane (and the like) is attributed to the freedom of rotation about the carbon-carbon single bond, so also the existence of stereosomenism between maleic and fumaric acids (and the like) is attributed to the lack of free rotation about the double bond.

It is interesting that van'! Hôff's models of ethane and ethylene CXXVI and XVI, respectively are consistent with the presence of free rotation about the single bond and the lack of it about the double bond. Since the two carbon atoms in ethane are pointed by just one linkage, no forces exist in the model XXVI to favour any one conformation over any other. Consequently, rotation might be expected to be easy in the molecule also. On the other hand, since the two carbon atoms in ethylene are joined by two bonds, the model XVI is held rigidly in the planar form. Consequently, the content of the proposition of the content of the proposition of the model of the content of the proposition of the model of the content of the

Plane Projection Diagrams.—The use of three-dimensional models of the sort employed by wart Hoff becomes extremely cumbersome if the molecule to be represented is even moderately complicated. Moreover, such models cannot be depicted very conveniently on a plane surface, such as a printed page; even the relatively simple dangama XXVII and XXVII, for example, are not too easily intelligible, and the situation rapidly becomes worse as the complexity of the molecule increases. Consequently, some simpler method of representation is highly desirable.

The convention has been generally adopted of representing the three-dimensional models by what are called plane projection diagrams or, more simply, plane configurations. Thus, by definition, the diagrams XXXI and XXXII represent the dextro-rotatory and laevorotatory forms, respectively, of glyceralded, the solution of the plane of the destro-rotatory described by the plane of th

specify the absolute configurations (i.e, the true three-dimensional forms of the actual molecules) The diagram XXXI, for example, can be considered the projection of either XXXIII or XXXIV; similarly, XXXII can be considered the projection

either of XXXV (identical with XXXIV) or of its enantiomorph XXXVI (identical with XXXIII).

The usefulness of the plane configurations like XXXII and XXXII. (The CH2OH group is not affected by the rotation XXXII lies in the fact that they make possible the unique representation of relative configurations. Thus the statement that a given substance CPRST (where P, R, S and T are any specified atoms or groups) has the configuration XXXVII implies that its true three-dimensional form is really XXXVIII (or XXXIX) if that of the dextrorotatory glyceraldehyde is really XXXIII (or XXXIV), respectively In other words, the plane projection diagrams define the configurations of the substances to which they refer by comparing them with that of glyceraldehyde; they do not

give the absolute configurations of the corresponding substances any more than XXXI gives that of the dextrorotatory glyceraldehyde

Considerable care must be exercised in the use of the plane configurations, since errors and inconsistencies can easily be introduced It might appear, for example, that the diagrams XXXI and XXXII are identical since a rotation of 180° about a vertical axis lying in the plane of the paper would transform either into the other. Consequently, if XXXI and XXXII are to represent enantiomorphs, the convention must be adopted that a rotation which takes the figure out of the plane in which it is drawn inverts the configuration (ie., changes it into that of the enantiomorph) Further similar conventions also must be adopted if further similar discrepancies are to be avoided. Unfortunately, however, no unanimity exists at present among chemists as to exactly what all these remaining conventions are, consequently, the conventions outlined below, although they are self-consistent and generally satisfactory, cannot be said to be universally adopted.

Although a rotation of 180° out of the plane of the paper inverts the configuration, as stated above, any rotation within the plane of the paper leaves the configuration unchanged. Thus, XL, XLI and XLII are equivalent to XXXI and, like it, represent dextrorotatory glyceraldehyde On the other hand, the dia-

gram XLIII is configurationally undefined since it cannot be obtained from either XXXI or XXXII by any sort of rotation, whether within or out of the plane of the paper; in other words, it does not represent explicitly either the dextrorotatory or the laevorotatory enantromorph.

It is to be noted that freedom of rotation does not in general exist about the single bonds in plane projection diagrams of the present type (see Free Rotation, above). This is because a rotation about any bond in such a diagram requires that that part of the diagram which is rotated leave the plane of the paper. If this part is dissymmetric, then, according to the convention adopted it is inverted in the process, so that the resulting configuration is not equivalent to the original one. For example, a rotation by 180° of the lower part of XXXI about the upper carbon-carbon bond changes this configuration into the enantiomorphic one

since it is symmetric and so identical with its own mirror image ) These remarks, of course, do not imply any corresponding lack of freedom of rotation about the single bonds in the actual molecules or in the three-dimensional models, they have reference instead only to the conventions which must be adopted if the plane configurations are not to lead to self-contiadictions.

If a molecule contains a ring of atoms, its configuration may be expressed on a plane surface in either of two ways. When one of these methods is used, the diagram is written as if no ring were present, and then the fact that a ring is present is indicated, more or less as an afterthought, by the drawing in of the necessary bonds as long, and frequently curved, lines. Thus, the configura-tion of  $\alpha$ -d-glucose (see Carbohydrates) is often written as XLIV. When the second method of representation is employed, the ring is drawn as if it were a plane polygon approximately at right angles to the plane of the paper, and the substituents at-

tached to the ring atoms are represented by the appropriate symbols above and below the plane of the ring. Thus, the configura-tion of  $\alpha$ -d-glucose can be written as XLV; this diagram is to be considered equivalent to XLIV. Plane projection diagrams like XLV do not imply knowledge of the corresponding absolute configurations A molecule of glucose in which the upper horizontal line (of XLV) is in front of the paper, and the lower line is behind it, would be the enantiomorph of a molecule in which the upper line is behind the plane of the paper, and the lower line is in front of it; since the diagram does not signify explicitly which line is in front, and which is behind, it can be considered the projection of either absolute configuration. Neither do these diagrams imply that the rings are completely planar (see Strain Theory, below); they imply rather that the average positions of the atoms of the ring lie within a single plane.

The fact that the plane projection diagrams of the above types do not give the absolute configurations is not a defect, but rather a desirable feature. This is because the absolute configurations are not known with certainty. Any diagram which implies the absolute configuration might, therefore, be incorrect, but the present diagrams do not suffer from this disadvantage of implying more knowledge than is actually possessed. (Although no experimental method exists for the determination of the absolute configurations of optically active substances, these configurations could in principle be found by theoretical calculations The various attempts which have been made to carry through such calculations, however, have been extremely complex mathematically and have required the introduction of numerous very rough approximations Moreover, the answers obtained with different sets of approximations have not always been in agreement,)

The representation of an ethylenic compound is relatively easy since the two carbon atoms joined by the double bond, and the four other atoms joined by single bonds to these two, lie in the same plane. Consequently, diagrams like XXVIII and XXIX for maleic and fumaric acids, respectively, represent the absolute configurations. Such diagrams need no further discussion.

If a molecule contains several rings, several double bonds, or both rings and double bonds, the representation of its configuration may be rather difficult. In such instances, the conventional scheme just outlined often must be supplemented by the use of heavy and broken lines to represent bonds to atoms in front of to those employed in preceding sections of this article. Examples of such molecules are given below

Use of Plane Projection Diagrams for the Prediction of the Number of Stereoisomers .- The foregoing rather general considerations can be made more definite by a discussion of some specific examples of stereoisomerism. The dextrorotatory and laevorotatory glyceraldehydes are represented by the diagrams XXXI and XXXII, as has already been mentioned. That these two diagrams correspond to enantiomorphs is shown (according to the conventions adopted) by the fact that each can be considered identical with the reflection of the other in a mirror which is halfway between them and perpendicular to the plane of the paper Since there is only one asymmetric atom in the molecule, and no further source of molecular dissymmetry, these two enantiomorphs are the only possible stereoisomeric forms (As usual, the racemic modification is not considered a distinct substance.)

A molecule of tartaric acid. HO<sub>2</sub>C-CHOH-CHOH-CO<sub>2</sub>H. has two asymmetric carbon atoms (the two designated by asterisks). Since there are two possible configurations about each such atom, one might anticipate altogether 2×2, or 4, distinct stereoisomers, which could be represented by the diagrams XLVI-XLIX. Of these, however, the first two are equivalent masmuch as either is

transformed into the other by a rotation of 180° in the plane. Since these two equivalent diagrams are mirror images of each other, they must represent a substance which is identical with its own mirror image, and so optically mactive; they are, therefore, equivalent forms of the plane configuration of meso tartaric acid (see above). The optical inactivity of this substance follows also from the presence of a plane of symmetry in either of the two diagrams (s.e., from the fact that the upper half of either diagram is identical with the reflection of the lower half in a mirror perpendicular to both the plane of the paper and the central carboncarbon bond). On the other hand, the last two configurations, XLVIII and XLIX, are not equivalent since neither can be transformed into the other by any rotation in the plane. Since they are mirror images of each other, they must be enantiomorphs, and so one must represent the dextrorotatory, and one must represent the laevorotatory, tartaric acid. In a way which cannot be described in this article; XLVIII has been shown to belong to the dextrorotatory enantiomorph, and XLIX has been shown to belong to the laevorotatory one. Thus, the existence of the three known tartaric acids can be accounted for, and the prediction that no further stereoisomers are possible can be made. (The diagrams XLVIII and XLIX have centres of symmetry, but neither the molecules which they represent nor the three-dimensional models of which they are projections do; conclusions regarding the presence or absence of centres of symmetry cannot easily be drawn from the plane projection diagrams of this type. However, see the discussion of the cyclic compounds, below.)

The trihydroxyglutaric acids, HQ2C-CHOH-CHOH-CHOH-CO2H, have the three asymmetric carbon atoms marked by asterisks. (The central carbon atom may appear not to be asymmetric since two of the groups attached to it are structurally identical. It is customary, however, to regard such atoms as asymmetric since the attached groups may differ in configuration. Atoms of this type are sometimes said to be pseudoasymmetric.) some might expect 23, or eight stereoisomeric forms, but, as with the tartaric acids, the number is reduced somewhat by the occurrence of meso forms. Only the four nonequivalent configurations

and behind the paper, respectively, or by other devices analogous L-LIII can be drawn, and, in agreement with prediction, only four stereoisomeric substances are known It is easily seen that L and LI represent two different meso forms since each has a plane of symmetry (passing through the central CHOH group

and perpendicular to the paper), and that LII and LIII represent a pair of enantiomorphs

The aldohexoses (see Carbohydrates) have five asymmetric atoms in the pyranose structure (cf the configurations XLIV and XLV of α-d-glucose). Since no meso forms are possible, 25, or 32 different optically active stereoisomers should exist. As has already been mentioned, all these forms are known

The cyclohexane-1,2-dicarboxylic acids, like the tartaric acids, contain two equivalent asymmetric carbon atoms, consequently, they also exist in two enantiomorphic forms, LIV and LV, and one meso form LVI. It is readily verified that the configurations LIV and LV are mirror images of each other, and that neither possesses a plane or centre of symmetry. On the other hand, LVI has a plane of symmetry perpendicular both to the ring and to

LVI the bond joining the two asymmetric atoms; it is, therefore, identical with its mirror image.

The isomerism of the cyclohexane-1,2-dicarboxylic acids (as well as that of other analogous cyclic compounds) is frequently described by the statement that the optically active forms LIV and LV are trans, whereas the meso form LVI is cis This nomenclature is convenient since it expresses clearly and concisely the relative positions of the substituent groups with respect to the plane of the ring. However, it has given rise to much confusion since it suggests a false analogy with the cis-trans isomerism in ethylenic compounds like maleic and fumaric acids (see above). Indeed, the statement is often encountered that the isomerism of the cyclic compounds is due to a restriction of rotation by the more or less rigid ring, just as that of maleic and fumaric acids is due to a restriction of rotation about the double bond. In the former substances, however, the rigidity of the ring is not significant; the isomerism, being due to the presence of two asymmetric atoms, would persist if the ring were perfectly flexible, or even if it were broken to form a noncyclic compound (so long as the asymmetry of the carbon atoms is not destroyed).

In cyclohexane-1,4-dicarboxylic acid, cis and trans forms again exist. Here, however, both the cis form LVII and the trans form LVIII have planes of symmetry and so are optically inactive.

111111

carboxylic acids) is not due to the rigidity of the ring, no conceivable rotation about any bond or bonds in the ring could

transform either isomer into the other, even if the ring were perfectly flexible.

Alanine anhydride (dimethyldiketopiperazine), with a six-membered ring, exists in cis and trans forms. Here, the trans form LIX has a centre of symmetry (at the centre of the ring) and so it is optically inactive (The presence of the centre of symmetry is apparent if the ring in LIX is visualized as lying in a plane perpendicular to that of the paper; on the other hand, if the con-

figuration is written instead in the equivalent manner as LX, the presence of the centre of symmetry cannot be so easily seen.)
The cis form has neither plane nor centre of symmetry, and so it exists in the two enantiomorphic forms LXI and LXII.

Optically Active Allenes and Their Analogues .-- van't Hoff pointed out that, if his tetrahedral model of the double bond (see above) is correct, the two CH2 groups in allene, H2C=C= CH2, should he in planes which are at right angles to each other; and that a substance with the structure RSC=C=CRS, where R and S are any two different atoms or groups, should exist in the enantiomorphic forms LXIII and LXIV. It was not until 1935,

however, that this prediction was verified by P. Maitland and was verment of the time the optically active diphenyldi-\alpha-naphthylallene LXV. In the same year, E. P. Kohler, J. T. Walker and M. Tishler reported the preparation of the similar

The isomerism of these two substances (like that of the 1,2-di- optically active allene LXVI. It is of interest that neither of these substances contains an asymmetric atom.

Although the existence of optically active allenes was not confirmed until comparatively recently, several analogous substances have been known for a longer time. These substances may be considered related to the allenes proper by the replacement of one or both of the "two-membered rings" (i.e., double bonds) by larger rings. Two typical pairs of enantiomorphs are represented by the configurations LXVII and LXVIII, and LXIX and LXX.

$$C_{\text{H}_{1}C}$$
 $C_{\text{C}}$ 
 As with the allenes, none of these substances contains an asymmetric atom

Optically Active Biphenyls .- In 1922, G. H Christie and J. Kenner found that the dinitrodiphenic acid LXXI can be separated into a pair of enantiomorphs. The present interpreta-tion of this fact is that the molecules of the two substances have the configurations LXXII and LXXIII The two rings here are considered to lie in approximately perpendicular planes. Since a rotation of 180° about the central carbon-carbon bond would transform other enantiomorph into the other, the assumption must be made that such rotation is impossible. The factor responsible for this restriction of rotation is presumed to be the size of the four substituents attached to the rings. In order for a molecule to pass from one enantiomorphic form to the other,

it must, at some time during the process, assume a configuration in which the two rings are coplanar; if this should happen, however, the substituent groups mentioned would be forced to come so close together that they would get in one another's way. In other words, it is difficult, or impossible, for the large nitro and

other words, it is unicula, or impossible, in the large interaction arrows, groups to slip past one another.

Evidence to support this interpretation of the optical activity of the dinitrodiphenic acid LXXI is provided by the observed regularities in the occurrence of optical activity in related subcontains no substituents that are themselves dissymmetric) can be active only if, first, neither of the two rings individually possesses a plane of symmetry except for the plane of the ring itself; and, second, several bulky substituents are present in the ortho positions Thus, the substance LXXIV cannot be obtained in optically active forms although the two rings are presumably not coplanar, the plane of the ring with the nitro and carboxyl

groups is a plane of symmetry of the molecule. Moreover, the further substance LXXV cannot be obtained in optically active forms although the noncoplanar configuration would be dissymmetric; the fluorine atoms are apparently too small to restrict the rotation. Intermediate cases are known in which the ortho substituents are large enough to permit optical activity, but not large enough to prevent a more or less rapid loss of activity resulting from spontaneous interconversion of enantiomorphs, such

$$\begin{array}{c|c}
F & F & NO_2 \\
\hline
 & CO_3H & NH_2 \\
\hline
 & LXXVII \\
\end{array}$$

a substance is represented by the structure LXXVI, (All attempts to racemize the dinitrodiphenic acid LXXI have been unsuccessful.)

A few further examples of similar type are given by the substances LXXVII-LXXXI. The naphthalene derivative LXXVII may be considered an optically active biphenyl with only three

ortho substituents; a more typical example is provided by LXXVIII. In LXXIX and LXXX, the presence of only two ortho substituents is sufficient to permit an easily lost activity. In LXXXI, some not completely conclusive evidence suggests that even a single ortho substituent, if it be sufficiently large, may permit activity.

As with the allenes and their analogues, none of these substances possess asymmetric atoms.

Optical and Geometrical Isomerism .-- As has already been mentioned, stereoisomerism is often subdivided into optical and geometrical isomerism. The distinction between these two types of isomerism does not now appear to be as significant as it did (+)-Chlorosuccinic Acid

stances It has been found that a derivative of biphenyl (which when it was first introduced; nevertheless, it has been retained by most chemists for historical reasons. A simple and precise definition of optical and geometrical isomerism appears to be impossible On the one hand, many pairs of substances must be considered both optical and geometrical isomers of each other at the same time, and, on the other hand, no complete unanimity exists among chemists as to exactly where the dividing line between these two types of isomerism is to be drawn. The following remarks are devoted to a brief statement of the basic principles involved, and they make no claim to either completeness or preciseness (or even to complete self-consistency).

A typical example of geometrical isomerism is provided by maleic and fumaric acids, to which, as was stated above, the configurations XXVIII and XXIX, respectively, have been as-

signed The characteristic feature of these two substances which is of interest here is that, as a result of the rigidity of the double bond, the two carboxyl groups, the two remaining carbon atoms, and the two remaining hydrogen atoms are held in the same plane In general, two stereosomers are said to be geometrical isomers of each other if they differ only in the relative positions in space of six coplanar atoms or groups of atoms (With certain nitrogen compounds, either one or two of these atoms or groups may be missing See Stereochemistry of Nitrogen, below.)

A slightly different example of geometrical isomerism is illustrated by the cyclohexane-1.4-dicarboxylic acids, LVII and LVIII Here, the significant six atoms or groups are the hydrogen atoms, the carboxyl groups, and the carbon atoms contained in the two HCCO2H groups Since the six-membered ring is presumably somewhat flexible (see *Free Rotation*), and since it is presumably not completely planar (see *Stram Theory*, below) the atoms and groups under consideration are not held rigidly in the same plane. Consequently, the situation with these acids is not exactly similar to that with maleic and fumaric acids. Nevertheless, the average positions of the atoms and groups are doubtless coplanar (and lying in a plane perpendicular to that defined by the average positions of the atoms forming the six-membered ring); consequently, the isomerism may again be considered geometrical.

In the cyclohexane-1,2-dicarboxylic acids, LIV, LV and LVI, the hydrogen atoms, carboxyl groups, and carbon atoms of the two HCCO2H groups are not coplanar, even on the average. Consequently, these substances may be called optical rather than geometrical isomers of one another. This conclusion seems logical in any event, in consequence of the close analogy with the tartaric acids, which are often given as typical examples of optical isomers. However, a number of writers prefer to classify the mactive cis acid LVI as a geometrical isomer of the two enantiomorphic trans acids LIV and LV, which are themselves optical isomers of each other. This is merely one example, out of many, of the difficulties encountered in the attempt to define unambiguously the distinction between optical and geometrical isomerism.

In spite of the difficulties briefly referred to, the distinction between optical and geometrical isomerism is clear and unambiguous in a large number of instances. In such instances, it provides a convenient method of classification (if it is not considered to possess more fundamental significance than it actually does).

Walden Inversion .- In 1893, P Walden discovered the cycle

of reactions indicated below	:	
HO <sub>2</sub> C—СН <sub>2</sub> —СНОН—СО <sub>2</sub> Н	PCl₅	HO <sub>2</sub> CCH <sub>3</sub> CHClCO <sub>3</sub> H
(+)-Malic Acid	KOH	(-)-CHLOROSUCCINIC ACID
Ag <sub>2</sub> O↑		Ag₃O↓
$HO_2C-\!\!-\!\!\!\!\!\!-\!$	PCl <sub>5</sub>	$\mathrm{HO_2C-CH_2-CHOH-CO_1H}$
(1) 0	KOH	( ) 25

Thus, by treating either of the optically active malic acids first with phosphorus pentachloride (in chloroform solution) and then with potassium hydroxide (in aqueous solution), he was able to transform it into its own enantiomorph, similarly, by treating either of the active chlorosuccine acids first with silver oxide and then with phosphorus pentachloride, he was able to transform it also into its enantiomorph (In each sequence of reactions, considerable racemization occurs, so that the activities of the final products are not very great Othes similar sequences were discovered subsequently, however, in which relatively little racemization occurs).

It is evident that, in one (and only one) reaction of the two in each of these sequences (ie, in either the reaction with silver exide or the one with phosphorus pentachloride, but not in both), the entering substituent at the asymmetric atom does not take up the same relative position in space as that formerly occupied by the substituent which it replaces. The change in configuration which thus results is called an inversion or, more precisely, a Walden inversion (The expression "Walden inversion" was innoduced by E Fischer in 1906 Originally it referred to the complete sequence of reactions by which the ontically active substance is converted into its enantiomorph, and not to the single eaction in which the inversion of configuration occurs Later, lowever, the expression seems more usually to refer to the single eaction, it is so used in this article ) The problem of identifying he particular reaction in which the inversion occurs is a difficult From evidence which cannot be described here, however, he conclusion has been drawn that inversions occur in the reacions of the above scheme in which phosphorus pentachloride and octassium hydroxide participate, but that there is retention of onfiguration in the ones with silver oxide. It is to be especially noted that the fact that the sign of rotation changes in the first we types of reaction but not in the last is purely accidental; the ign of rotation often changes in reactions which are considered o proceed with retention of configuration, and, conversely, it often remains the same in reactions which are considered to proeed with inversion. No necessary relation exists between the onfigurations and signs of rotation of nonenantiomorphic sub-

By 1946 the view was commonly held that every reaction in which one substituent atom or group is replaced by another is companied by an inversion of configuration about the atom at which the replacement occurs. Reactions, like that between hibrorescurne acid and silver oxide, in which no net inversion is onsidered to occur, are interpreted as proceeding in two steps, with an inversion meach; two mersions, of course, are equivaent to a retention. No inversion is considered to occur at atoms t which no substitution takes place.

A probable mechanism of the Walden inversion is shown schenatically in fig. 2. In part a, representing an early stage of the eaction, the reagent R approaches the carbon atom from the side poparie the substituent S; in part b, representing the mid-point of the reaction, the atoms or groups R and S are equidistant from he carbon atom, which is no longer tetrahedral; and in part c, epresenting the conclusion of the reaction, the displaced subtituent S as departing, and the entering one R; is attached to the arbon atom. In the process, the molecule has been "turned sade-out" like an umbrella in a path wind.

a. An early stage b. Mid-point c. Conclusion

FIG. 2 -A PROPOSED MECHANISM OF THE WALDEN INVERSION

Optically Active Series.—The sign of the rotation produced y an optically active substance can occasionally be reversed by change in the experimental conditions (see Specific Rotation, love).—'A further factor, which similarly introduces confusion to stereothering classification is that a parent substance often

gives derivatives of identical configuration but with opposite sign of rotation For example, the salls and esters of the laewrotatory lattic and, CH2-CH0H-CO-H, are destroratory; those of the destroratory and are laevrotatory. For these reasons, it will seem destrobate to include in the complete name of an optically active substance and sis independent of the sign of rotation. This symbol would then remain unchanged when the substance, under different conditions, exhibits different signs of rotation, on when it forms derivatives of composite rotation, or

when it forms derivatives of opposite rotation.

It may be doubted whether any completely general and completely unambiguous classification of configurations of the type desired is possible; certainly, no such classification has as yet been derived. Nevertheless, a scheme has been developed wheth armounds of the complete of the compound of the complete of the compound this scheme consists in dividing configurations into those of the so-called d-series and those of the I-series (or p-series and L-series, respectively) on the basis of the genetic relationships among them. A substance is then said to belong to the d-series (or I-series) are series; and consists of the genetic relationships among them.

A substance is then said to belong to the d-series (or I-series), respectively, and so on

In order that an optically active series may be set up, some particular substance must be defined as belonging to the d-or lesens, so that the remaining substances may be related to it. Originally, Emil Fischer chose the instural dextroordatory glucose as the prototype of the d-series, and, accordingly, he named this substance d-glucose Later, dextroordatory glyceraldehyde, XXXII, was chosen instead (M. A. Kosanofi, 1905), these two conventions lead to the same assignment of series, so that no ambiguity results.

The way in which the optically active series are built up can be illustrated by a few examples. As has been mentioned before, (+)- and (-)-glyceraldehyde are by definition assigned the configurations XXXII and XXXIII, respectively. Also by defintion, they are said to belong to the d- and l-series, so that their

complete names are d(+)- and l(-)-gy/ceruldehyde, respectively. By well-known methods (see Carsoursparts), the aldehyde group (CHO) of each of these substances can be changed into a CHOH-CHO group. Since this larger group contains an asymmetric carbon atom not present in the original, each of the glyceraldehydes can give rise to two products (which, not being canatiomorphs, need not be formed in equal amounts). Thus d(+)-glyceraldehyde gives rise to LXXXIII and LXXXIII, which are, therefore, said to belong to the d-series. Similarly,

l(-)-glyceraldehyde gives rise to LXXXIV and LXXXV, which are said to belong to the l-series.

The procedure can be continued further. Each of the tetrose LXXXII-LXXXV can be transformed into two pentoses, each of which can in turn be transformed into two hexoses, and so on. In each reaction, the two products belong to the same optically active series as the substance from which they were made. In general, and without explicit reference to the sequence of reactions starting with the glyceraldelydes, the optically active series to which any monosuccharide belongs may be said to be determined by the configuration about the asymmetric carbon atom farthest carbon atoms is written vertically and with the carbonyl group at the top, the hydroxyl group upon the atom in question is to the right of the chain in the d-series, and to the left in the l-series

If the glyceraldehydes are oxidized, they give the glyceric acids LXXXVI and LXXXVII. The first of these, even though it is

laevorotatory, is said to belong to the d-series on account of its genetic relationship to d-glyceraldehyde; it is accordingly called d(-)-glyceric acid Similarly, the substance LXXXVII is called l(+)-glyceric acid In general an  $\alpha$ -hydroxy acid is said to belong to the d-series if it contains the grouping LXXXVIII, and to belong to the 1-series if it contains the grouping LXXXIX instead. If more than one -CHOH-CO2H group is present in the

molecule, this definition of d- and l-series may become ambiguous; consequently, the series are not often employed with such substances (except with the tartaric acids, with which there is no ambiguity).

The arbitrariness of the present definition of optically active series can be made apparent by a further consideration of the glyceric acids. The acid LXXXVI was said to belong to the dseries because of its formation from the d-aldehyde XXXI In principle, however, it could be formed equally well from the i-aldehyde XXXII instead; if, in XXXII, the primary alcohol group at the bottom is oxidized to a carboxyl group, and if the aldehyde group at the top is then reduced to a primary alcohol group, the resulting configuration is XC, which is seen to be

equivalent to LXXXVI. Of course, this second transformation is more complicated than the first, but logically the two are on the same basis. Only considerations of convenience have led to the adoption of the first as the significant one.

Strain Theory.-In 1885 A Baeyer called attention to the fact that nearly all the then known carbocyclic compounds (ie, cyclic compounds with only carbon atoms in the ring, or rings) contained either five- or six-membered rings. To explain this fact, he brought forth a group of ideas now called the strain theory. The angle between any two single bonds formed by a saturated carbon atom had been postulated by van't Hoff to have the tetrahedral value of 109° 28' (see above). Consequently, Baeyer considered that an angle of this magnitude might be assumed to be most stable, so that, if one or more angles in a molecule were forced in some way to have a widely different value, the molecule would be "strained" and therefore, unstable: Now, in cyclo-propane XCI, the C-C-C angles of the three-membered ring must be equal to 600; since this value is much smaller than the preferred roo 28', the molecule is strained. Thus, Baever considered that the difficulty of preparing such a substance is accounted for. Similarly in cyclobutane XCII, the angles would have to be equal th 90° if the four-membered ring is planar; again considerable strain is present, and again the difficulty of preparing the substance appears to be explained. The minimum

removed from the carbonyl group (C=O), when the chain of strain is reached with cyclopentane XCIII, in which the planar ring would require bond-angles of 108°, almost identical with the tetrahedral value. With still larger rings, the strain increases regularly with the size if, as before, the rings are considered to be planar. The six-membered ring of cyclohexane XCIV requires an angle of 120°, the seven-membered ring of cycloheptane requires one of 128° 34', and so on. Thus, the least strain occurs

in just those rings which are easiest to prepare and best known Baever's original ideas, although still considered essentially correct, have undergone extensive modification. In 1946 it was believed (H. Sachse, 1890) that the strain postulated by Baeyer exists only in the three- and four-membered rings, but that no strain exists in the rings of six or more atoms. With the small rings, the least strain results if the rings are planar as assumed by Baeyer, but, with the larger rings, the strain can be relieved completely if the ring is permitted to be puckered. With cyclohexane, for example, two different strain-free configurations are possible; these are shown in XCV (the so-called boat-form or C-form) and XCVI (the so-called chair form or Z-form) Ap-

parently, transitions among the various forms of these puckered rings are so easy that isolation of stereoisomeric substances, differing only in the form of the ring, is impossible.

The assumption that the rings with six or more atoms are puckered and stram-free permits the conclusion to be drawn that such large rings should be as stable as those with five atoms, and, in fact, as stable as the noncyclic chains. This conclusion is verified experimentally. There is no significant difference, referable to strain, between, say, cyclotriacontane, with 30 atoms in the ring, and cyclopentane, with only 5; nor is there any significant difference between either of these substances and any of the typical paraffin hydrocarbons (see Paraffin Hydrocarbons, Chemistry of). In particular, neither ring can be broken easily by ordinary chemical reagents, and the heats of combustion of the two cyclic substances (see Thermochemistry), per CH2 group, are practically identical. (In contrast, the threemembered ring in the strained cyclopropane XCI is easily broken by reagents like bromine, hydrogen in the presence of a platinum catalyst, and hydrogen chloride, which have no similar effects upon cyclopentane, cyclotriacontane, or a paraffin hydrocarbon; and the heat of combustion of cyclopropane, per CH2 group, is appreciably higher than that of either cyclopentane or cyclotriacontane.)

The reason why Baeyer was misled into believing the large rings to be strained was that, experimentally, such rings are difficult to prepare. In 1946 this fact was interpreted differently. The difficulty of preparing cyclotriacontane, for example, was then explained as the result, not of any assumed instability of the product, attributable to strain, but rather to the improbability that the two ends of a chain of 30 carbon atoms will happen to come close enough together to permit being joined to each other by a bond. The relative ease of forming the five-membered ring in cyclopentane, on the other hand, is attributed to the relatively great probability that the ends of a much shorter chain of only five carbon atoms will come close enough. In other words, the fact that the five- and six-membered rings are the most easily formed of all is explained as the result of two opposing effects; a lesser extent) four-membered rings, and the probability factor, since different methods of formation of a given salt, such as which causes the ease of formation to decrease more or less regularly as the size of the ring increases

An important service performed by the strain theory consists in providing a reasonable explanation of the nonexistence of certain substances For example, cyclopropyne XCVII is unknown although, as far as the ordinary rules of valence are concerned, it would appear to be a perfectly reasonable substance However, if it existed, it would be extremely strained since the normal value of C-C=C bond angles is 180°. Similarly, cyclohexene might be expected to be obtainable in cis and trans forms, analo-

gous to maleic and fumaric acids, respectively. Only the cis form XCVIII is known; the trans form XCIX would be too highly strained to be capable of existence. Moreover, camphor C (see Camphors) has the two asymmetric carbon atoms marked with the asterisks Since these atoms are nonequivalent, meso forms are impossible, and so two pairs of enantiomorphs might be expected Only one such pair is known. This is the one in which the attachment of the -C(CH3)2- "bridge" to the outer six-membered ring is cis; the second pair of enantiomorphs, in which the attachment is trans, would be too strained to be capable of existence.

## STEREOCHEMISTRY OF NITROGEN

The general principles essential to the understanding of the stereochemistry of the elements other than carbon differ in no significant respect from those essential to the understanding of the stereochemistry of carbon itself. Since these principles are described in considerable detail in the preceding sections of this article, they need not be discussed further here. Moreover, since the factual material relating to the stereochemistry of the remaining elements is relatively restricted (although rather extensive in an absolute sense), a brief survey of the field is sufficient to bring out the important features.

In all optically active compounds known up to 1899, the molecular dissymmetry was dependent upon the spatial arrangement of the valencies of carbon In that year, however, W. J. Pope and S. J. Peachey discovered that quaternary ammonium salts of the type [NQRTZ]+ X- (where Q, R, T and Z represent four dissimilar hydrocarbon radicals) could be resolved into enantiomorphs, and hence that the valency configurations of other elements besides carbon could have sufficient permanence to make their stereochemical investigation possible. (J. A. Le Bel had stated earlier that he had obtained an optically active substance of this type, but his work was shown to be incorrect.) Thus a wide field of research was opened. Further work on quaternary ammonium salts showed. (1) that, since molecular dissymmetry could no longer be demonstrated when two of the hydrocarbon radicals were identical, the ion [NQRRT]+ probably has a plane

the strain, which operates against the formation of three and (to the configuration about the nitrogen atom may be); and (2) that,

$$NQRT + ZX \rightarrow [NQRTZ]^+X^- \leftarrow NRTZ + QX$$

never yielded isomeric modifications, the valencies linking the four hydrocarbon radicals to the nitrogen atom are most probably equivalent. Only two configurations of the ammonium ion satisfy these conditions, namely, the pyramidal configuration I and the tetrahedral configuration II, of these, the first has been definitely disproved by W H. Mills and E H Warren (1925), who showed

that an ammonium salt, containing an ion of the type III, can be resolved into optically active components. It can indeed easily be seen that, if the two rings in this ion were attached to the base of a square pyramid, as in IV, the ion would have a plane

$$\begin{bmatrix} CH_1 & CH_1$$

of symmetry and the compound would be nonresolvable. In the ammonium ion, the nitrogen atom must accordingly have the tetrahedral configuration II corresponding with the asymmetric configuration of its derivative III.

The amine oxides are another class of compound in which a nitrogen atom forms bonds to four distinct other atoms or groups In these also, the radicals appear to be tetrahedrally disposed about the nitrogen atom, for amine oxides of the type V have been obtained in optically active forms by J. Meisenheimer (1908).

The configuration of the trivalent nitrogen atom is of special interest on account of the number and importance of the comof symmetry (no centre of symmetry is possible here, whatever pounds in which the element is present in this state. The numerous attempts made to obtain optically active compounds of the type NQRT have all given negative results, but it is not afte to conclude from this fact that these compounds have a planar configuration, it is possible that instead they have the dissymmetric pyramidal configuration VI but are racemized easily by passage through an intermediate planar configuration, thus

It is reachly verified that VIII is the enantiomorph of VI, and that VIII is symmetric so that its probabilities of reverting to'll and VIII are equal. That this second explanation of the optical inactivity of ammes of the form NORT is the correct one has been shown by studies of spectra, of dipole moments, of crystal structure, and of electron diffraction.

In compounds of trivalent narrogen of the type -X = N - Y, where the natrogen atom is directly linked to only two other atoms, and, therefore, to one of them by a double bond, the strenchemistry of the nitrogen atom was established at an early date by the classical stereochemical methods ( $t \in N$ ) consideration of isomer numbers and not with the use of the physical methods employed with the amines). Thus, coimnes can generally be prepared in two isomeric modifications if the two substituents attached to the carbon atom doubly bonded to the instrogen are dissimilar. The two forms are represented by the configurations IX and X. That this interpretation is correct is supported by the

fact that the isomerism is repeated in the O-methyl ethers XI and XII, for which no alternative structures are possible. In these configurations, IX-XII, the carbon, introgen and oxygen atoms, and the atoms of the groups R and T joined directly to the central carbon atom are considered to lie in the same plane. The situation is thus closely analogous to that in the ethylenic compounds considered previously, like maleic and fumaric acids; the only spifficient difference is that the nitrogen atom here forms three bonds whereas the corresponding carbon atom in the ethylenic compounds forms four. (Sometimes, the statement is made that the unshared pair of electrons on the introgen, represented by the pair of dois, acts as a fourth valence bond.

The above interpretation of the isomerism of the oximes, due to A. Hantzsch and A. Werner (1890), is confirmed by the optical activity of the cyclic oxime XIII, demonstrated by W. H. Mills

and A. M. Bain (1910); the molecule of this compound can be dissymmetric only if (i) the hydroxyl group does not be in the plane perpendicular to that of the six-membered ring, and (2) the C-N-O bond angle is not 180°. These are exactly the same geometrical conditions postulated by Hantzech and Werner. (For further discussion of the stereochemistry of the oximes, see

Further examples of stereoisometic nitrogen compounds, which we their isometism to restricted rotation about a double bond to the nitrogen atom, include the N-methyl oximes XIV and XV, the azo compounds XVI and XVII and the azony compounds XVIII and XIX. The so-called stable and labile diszohydrates (see Diazo Comprounds Novement about only dispersion to be seen to a considered by Hantsech to be

R-C-T	R-C-T	R-N	RN

stereosomers of each other with the configurations XX and XXI, expectively, this view, however, up to 1946 had never been definitely shown to be correct, and it has been denied by other authors. It is evident that a marked difference exists between the configurational stability of those compounds of trivalent introgen in which each nitrogen atom forms three single bonds and that of those other compounds in which each nitrogen atom forms one single and one double bond. The theoretical reason for this difference is not understood

#### STEREOCHEMISTRY OF THE REMAINING ELEMENTS

For reasons of convenience, the various remaining elements are classified below on the basis of their co-ordination numbers. In general, a given element in a given compound is said to have a co-ordination number N, or to be N-co-ordinated, if in the molecules of that compound each atom of the element in question is joined to N distinct other atoms by bonds that are not broken ionically in solution For example, in sulphuric acid, H2SO4, the co-ordination number of sulphur is four, since each sulphur atom is joined to four oxygen atoms by bonds of the type stated, similarly, the co-ordination number of oxygen in the same substance is one, since the oxygen-hydrogen bonds are broken ionically in solution and so do not contribute to the co-ordination number. In those instances in which the "nonionizable" union between each atom and each of its neighbours consists of a covalent single bond, the co-ordination number of each atom is equal to its valence.

Elements of Co-ordination Number 3.—Sulphonium salts [SQRT]\* X\*, in which three dissimilar hydrocarbon radicals are linked to the sulphur atom, were shown to be dissymmetric by W. J. Pope and S. J. Peachey and by S. Smiles (1900); the sulphonium ion, therefore, has a nonplanar configuration as in XXII. Other analogous compounds of sulphur are the sulphum esters XXIII, the sulphoxides XXIII vand the sulphilimines XXV, each

of these has been shown to have a similar nonplanar configuration, since optically active representatives of the three classes have been obtained, principally by H. Phillips and J. Kenyon (1925-27)

Optically active selenonum salts (analogous to the above suiphonum salts) were obtained by W. J. Pope and A Neville (1902), and optically active telluronium salts were obtained by T. M. Lowry and F. L. Gilbert (1925). Consequently, the conclusion can be drawn that 2-co-ordinated selenoum and tellurium are nonplanar, even though attempts to obtain active selenoxides and tellurium oxides (analogous to the sulphoxides) have failed.

That trivalent arsenic is able to maintain a pyramidal configuration has been shown by the resolution of an arsine, AsRQT, with three dissimilar substituents. In this respect, arsenic resembles sulphur, selenium and tellurium rather than introgen.

Optically inactive stereoisomers of presumably the cis-trans type have been obtained when two trivalent arsenic atoms are present in a ring

Elements of Co-ordination Number 4 .- In the first short period (see Periodic Law, The), besides carbon and nitrogen, the elements beryllium and boron can have co-ordination number four, and there is evidence that the atoms of each of these elements then have the four radicals tetrahedrally disposed about them This was demonstrated for beryllium by the production of an optically active compound of the type XXVI (W H Mills and R A Gotts, 1926), and for boron in a similar way by H<sub>2</sub>N-CH<sub>2</sub>-CH<sub>2</sub>-NH<sub>2</sub> (or of two nitrito groups, NO<sub>2</sub>, by an J Boeseken and J Meulenhoff (1924).

The molecular dissymmetry of silicon compounds of the type SiORTZ has been established by F. S Kipping, and the investigation of the configuration of 4-co-ordinated copper and zinc by the method used for 4-co-ordinated beryllium has shown that their valencies are also tetrahedrally distributed. Phosphorus and arsenic, like nitrogen, have also been shown to have the tetrahedral configuration when 4-co-ordinated-phosphorus through

the optical activity of a phosphine oxide XXVII (I. Meisenheimer and L Lichtenstadt, 1911), and arsenic through that of an arsine sulphide XXVIII. Optically active arsine oxides ROTAS-O- and arsonium salts [ROTZAs]+ X- are also known The existence of diastereomers and of meso forms has been demonstrated with compounds containing two such asymmetric phosphorus or arsenic atoms.

It is not universally true, however, that when an atom is linked directly to four other atoms these must be arranged around it tetrahedrally Thus, many compounds of 4-co-ordinated platinum containing a complex of the type PtA2B2 occur in two mactive, but evidently stereoisomeric, modifications, typical examples include the doubly charged cation  $[Pt(NH_2)_2(\hat{C}_6H_3N)_2]^{++}$  and the neutral molecule  $Pt(NH_2)_2Cl_2$  This isomerism is clearly incompatible with a tetrahedral arrangement of the radicals about the platinum atom and is to be explained most simply by the supposition that 4-co-ordinated platinum has a plane configuration, and that the isomers are of the types XXIX and XXX (known as cis and trans, respectively).

Elements of Co-ordination Number 6 .- Werner's proof that substances like the compounds of metallic salts with ammonia (formerly regarded as "molecular compounds") are coordination compounds in which a certain number of atoms or groups, most frequently six, are directly attached to the metallic atom (CoCl3.6NH3, for example, having the structure XXXI) brought with it the problem of determining how these six groups are disposed about the central atom. If it is assumed that the valencies by which they are attached are equivalent (and this is supported by the absence of isomerism which should otherwise occur), three arrangements are possible: the plane hexagonal XXXII, the prismatic XXXIII, and the octahedral XXXIV. (For ease of visualization, the respective geometrical figures are outlined, the central atom is represented by a large dot, and the valence bonds are not shown. A substituent is supposed to occupy

each of the positions marked by a corner of the figure.)

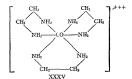

A decision among these three possible configurations was obordination positions together in pairs through four-membered matic, but in only two if it is octahedral, the alternative arrange-

chains, as can be done, for example by the threefold replacement of two molecules of ammonia, NH4, by one of ethylenediamine,

oxalato group "O2C-CO5 or the like) so as to produce a complex in which the metallic atom forms a common member of three symmetrical five-membered rings, as in XXXV Since it seems

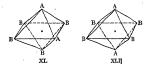

most probable that only adjacent co-ordination positions can be bridged in this way, the possible configurations for the tricyclic ion are those indicated by the dotted lines in the four different diagrams XXXVI-XXXIX Of these, the first three are evidently

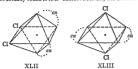

symmetrical, but the last is dissymmetrical, for it possesses only twofold and threefold axes of rotation Experimental investigation of the salts of these tricyclic ions has shown that they can be produced in optically active forms. The ions are thus dissymmetric and must consequently have the last configuration XXXIX It is, therefore, to be concluded that in such compounds the six

valencies of the central metallic atom are octahedrally disposed. This conclusion is confirmed by the occurrence of a different type of stereoisomerism shown by complexes of the type MA2B4,

such as are contained in the diacidotetrammine salts of cobalt and chromium These compounds should exist in three isomeric tained by investigating the compounds formed by linking the co-forms if their configuration is hexagonal and in four if it is prisments are then those in which the two groups A lie at the ends (1) of an edge as in XL (cis compound), and (2) of a diagonal The number of as in XLI (trans compound) of the octahedron isomers actually found is two. Moreover, in dicyclic derivatives of

this type like [en2CoCl2] + Cl-, where en represents ethylenediamine, the isomer with the cis configuration can be obtained optically active, whereas the other, the trans isomer, cannot be resolved These facts are in accordance with the configuration XLII for the cation of the cis isomer, and XLIII for the cation of the trans isomer

STEREOCOMPARATOR, an instrument for comparing two astronomical photographs of the same star field, commonly combined with a Blink microscope (q v).

STEREOPHOTOGRAMMETRY. In the earliest applications of photography to surveying, use was made of various simple graphical constructions or calculations in order to determine bearings and angles of elevation or depression from the camera station In order to simplify these constructions or calculations, the photograph was usually exposed in a vertical plane Two photographs, taken from the ends of a known base and treated in this manner, thus enabled a complete survey to be made of all visible ground in the area common to the pair. (See Photogrammetry.)

STEREOSCOPE. An optical instrument used for obtaining from two slightly different pictures (se., pictures or photographs of the same object but from a slightly different point of view), the impression of a single picture in relief. See BINOCULAR IN-STRUMENT

STEREOSCOPIC VISION: see VISION.

STEREOTYPING. A process of producing duplicate printing plates from a form of type or blocks by pouring molten metal on a matrix made in plaster of paris or papier-maché (See Print-ING.)

STERILITY is a term denoting failure of reproduction. It occurs throughout animal and plant life, but this article will be restricted to sterility in the human species. In searching for causes that contribute to the sterility of a couple, both sexes joined in marriage are considered. Through modern methods of investigation and treatment, many couples have been helped to rear children that would otherwise not have been born. In the human, absolute sterility is comparatively rare. It exists in individuals congenitally deficient in development of the sex apparatus and in rare cases of hermaphroditism and intersex or neuter individuals. The tact that by and large, at least 85% of married couples have children indicates the potential fertility of the vast majority of the population The incidence of sterile marriages varies in certain localities between 10% and 15%. As a rule, one or several barriers to conception may be discovered by careful investigation in one or both partners. Many of these sterility factors are acquired and many are amenable to correction, eventually leading to restored fertility unless the sex organs, particularly the sex glands, have been removed by surgical operation or by X-ray exposure or were destroyed by infection.

The concept of sterility underwent considerable change after 1900 owing to (1) increasing realization of the need for investigating both man and wife separately and conjointly, (2) greater appreciation of the general constitutional condition of each partner which is better assayed, (3) advances in investigative methods of estimating the physical, chemical and biologic factors involved. (4) newer concepts of endocrine disturbance, especially of the sex glands. (s) improved results of animal breeding and of artificial insemination. Although the ultimate cause or causes are not always ascertainable, many childless couples have become parents as a result of a thorough investigation which revealed and led to the elimination of the deterrent factors. There is thus much more hope for such barren marriages than was formerly the case.

Causative Factors.-The time factor as an index of sterility has been increasingly reduced so that in the opinion of some investigators six months of marriage without conception (providing contraceptive measures are not used) should lead to an inquiry into the reasons for the conceptional failure. The causes may be trivial or more serious. The earlier they are discovered the more amenable they may be to correction Of first importance is a careful clinical medical history of both married partners which includes the nature and number of surgical operations, unusual accidents, especially those affecting the genital organs, and exposure to X-ray A history of such diseases as mumps, malnutration, obesity, diabetes, hypertension and other metabolic and infectious disorders that the physician considers in appraising the general health of the individual helps to estimate their possible effect on the reproductive function and the chances of conception taking Occupational disorders following exposure to noxious chemicals, alcoholism, excessive smoking, morphinism, syphilis (hereditary and acquired), gonorrhoea, are among deleterious causes. Severe mental and physical strain and exhaustion affect the reproductive organs Psychic depression is particularly important in the male but not infrequently affects the female's ovarian function Excessive venery is unfavourable to both sexes from the reproductive point of view. Change of climate and of occupation not infrequently influences ovarian function unfavourably by inducing transient amenorrhoea and infertility in women.

Age has long been known to be a factor. Although many women 40 years old or more may conceive for the first time, their chances are not so great as those which favour younger women Should there be other physical obstacles, the matter of age becomes of great importance as the power of reproduction in females wanes just before and disappears at the menopause. For these reasons the effort to have children should be made earlier and the advantages of marriage in the early third decade of life need no further elaboration.

Proper sex instruction has value if given during high-school age

Contraception frequently masks sterility, leading to much loss of time when corrective measures may have been helpful. It is important therefore to make certain by appropriate examinations that no actual barriers are present early in married life before couples resort to contraception.

Concerning the investigation itself, each partner in the marriage is subjected to a thorough physical examination with special reference to the reproductive organs. The examination includes certain laboratory tests of the blood and urme and a basal metabolic rate determination Special examination is first made of the husband's semen par-ticularly for the number of spermatozoa, their morphological char-acteristics and biological activity when admixed with the gential secreons of the wife Examination of the seminal ejaculate itself is made when spermatozoa cannot be found in the vaginal and cervical canals within one or several hours after intercourse. If the husband fails to produce spermatozoa a testicular biopsy can determine whether this fault is due to blockade in the excretory duct (vas deferens) or whether

nate as the to diocease in the eventory direct (was deserms) or whether A nonsurgical method of assectationing whether the fallopian tubes or oldities are open or obstructed was made available by W. H. Cary and I. C. Rubin independently in 1924. As these dicte carry the oven the contract of the contra except by a surgical abdominal operation (laparotomy) which enabled the surgeon to inspect the canal of the fallonian tubes and probe it the surgeon to inspect the cann of the fallopian tubes and probe at the purpose consisted of the purpose to the purpose consisted of the purpose to the purpose to the purpose to the purpose to the purpose the purpose to the purpose the purpos can actually sterilize the woman

In 1910 I C Rubin adopted oxygen to insuffate the utreus instead of injecting solutions. Soon thereafter oxygen was replaced by CO<sub>0</sub> as the latter gas was found to be bette tolerated by the organism, after passing into the addominal cavity from where it was rapidly selvoride to the property of the control of the property of the pro

An important question in the case of the female is whether she ovulates regularly or rergularly or, in rare instances, not at all Although the pattern of the meistrual habit is againfant as a rule, the ownant function in an appreciable number of woman in bot normal, and the state of the sta

Therapeutic Measures—A therapeutic method used to advantage after about 1900 in case of stenily associated with delayed menstrain periods as low voltage X-ray irradiation to the ovanes. In more than 80%, the measural cycle was restored to normality by this method and me to than 1900 to the stenil to the steni

About 15% of infertile couples can be aded by a single measure such as uterotubal neutral by using additional therapeutic surroutes an extension substantial content of the surroutes and the surroutes and the surroutes and the surroutes and the surroutes are surrouted in about 50% of sterile marriages. The difference in the results of treatment depends upon the groups of the surroutes and the surroutes are surrouted to the overset. Cortisone has been found to be a powerful stimulant to the overset.

Rophysical and chemical studies recently made on the mucas of the cervice in relation to the vaishibity and transport of the spermatrous also had a promising future in the 1950s. Attention to the psychosomatic aspects of the sternlity problem as regards husband and wife here brought light on time which was appreciated for a long time has become better understood through psychoanizate study. For case of hopeless male sterility, as in azoospermia and cryptorcham, artificial unmeniantion, now increasingly in vogas, has provide a hoon to the Manawilla much can be accomplished by proper early education and Manawilla much can be accomplished by proper early education and prevention of acquired faults.

STERLING, JOHN (1806—1844), British author, was born at Kames Caste in Bute on July 20, 1806. He belonged to a family of Scottish origin which had settled in Ireland during the Cromwellian period. He was the son of Edward Sterling (1773—1847), who was for many years a leader writer on The Times, John Sterling was educated it Glasgov university and at Trinity college and Trinity Hall, Cambridge. At Cambridge he was a member of the famous "Aposthesi," club, With F. D. Maurice he purchased the Athenseum.in 1883 from J. Silk Buckingham, which was not a success.' In 1834 he was ordained and became curate at Hurstmanneaux, where his bill tutor Julius Hare was view. Acting on the adviceor'd hispolycial hard resigned his curacy in 1835, but, according to Carlife, the hydrian resigned his curacy suggest, given the opinions of, the, chapter, Heidel at Ventour on

Sept 18, 1844. Sterling owes his fame to the vivid Life by Carlyle, to whom, with Hare, his papers were entrusted

STERLING, a city of Colorado, US, 1:28 mi NE of Denver. on the South Platte niver and federal hiphways 6 and 138, served by the Burlington Route and the Union Pacific lailway systems, the county sea of Logan county. The population was 7,534 mi 1950 and 7,411 mi 1940 by the federal census. The city was founded in 1881 and incorporated in 1883. In 1900 the population

STÉRLING, a city of Whiteside county, III, U S, on the north hank of Rock river, I ton W. of Chacago It is on the Lincoln highway and the Hennepin canal feeder, and is served by the Butington Route and the Chucago and North Western railways, and by motor bus lines in all directions. Population was 12,817 in 190, and was 11,345 in 190, by the federal care Rock Falls (pop 7,983 in 1950) is just across the river router shave abundant water power and large manufacturing dustries, making agricultural implements Sterling was chartered as a city in 1845.

STERLING, a term used to denote money of standard weight or quality, especially applied to the English gold sovereign, and hence with the general meaning of recognized worth or authority, genume, of approved excellence The word was formerly derived from the name of "Easterlings" given to the north German mer-chants who came to England in the reign of Edward I and formed a guild in London Their coins were of uniform weight and excellence, and thus, it was supposed, gave the name of the moneyers to a comage of recognized fineness. This theory is based on a statement of Walter de Pinchbeck, a monk of the time of Edward I. The word, however, occurs much earlier in the French form esterlin (11th or 12th century) and the Latin libra sterilensium (1145); the Latin sterlingus occurs in an ordinance of 1184 and in a statute of Edward I ("denarius Anglia qui vocatur sterlingus") The derivation favoured by the Oxford Dictionary is from the late O.E. \*steorling, "coin with a star", some of the early Norman pennies carry a small star. In early instances the word often occurs in the phrase "pound of sterlings," originally a pound weight of such pennies, 240 of which went to the "pound sterling" of silver of 5,760 grains, 925 fine. "Sterling silver" was originally silver having the same degree of purity as these pennies; later silver of standard quality, and so marked The word was borrowed by most European languages and is there applied to English money. (See Money, Mediaeval.)

STERN, DANIEL: 566 AGOULT, MARIE CATHERINE SOPHIE
DE FLAVIONY

STERNE, LAURENCE (1713-1768). English humorist, was the son of Roger Steme, an English officer, and great-grand-so of an archeshap of York. He was born at Gomein, and the state of the sta

He was also a prebendary of York cathedral.

Sutton was Steme's residence for 20 uneventful years. He kept up an intimacy which had begun at Cambridge with John Rall-Stevenson (1718—1785), witty and accomplished epicturean, owner of Skelton Hall ("Crazy Castle") in the Cleveland district of Yorkshire. Stevenson's vanous occasional sallies in verse and prose—his Fables for Grown Genslemen (1761-1770), and his Gray Talles (1795), bear a resemblance in spirit and trum of thought to Sterne's work, interner as they are in Herrary genius. In F. Topham, R. York havyes, over the bettownl of an office in the gift

of the archbishop This sketch, in which Topham figures as Trim the of the archoistop I loss sacton, in World Tophan Ingues as a func-section, and the author as Lony Slim, gives an cannet of Stene's powers as a humoret. It was not published until after his death, while it appeared in 1769 under the title of A Political Romance, and after-ward the History of a Warm Watch-Cost. The his ratt two volumes, "Fristran Shandy were issued at York in 1753 and advertised in London

on Jan 1, 1760, and at once made a sensation

For the last eight years of his life after this sudden leap out of obscurity we have a faithful record of Sterne's feelings and movements scuricy we have a latitudi record of sterne's teenings and movements in letters to various persons, published in 1775 by his only child, Lydia Steine de Medalle, and in the Letters from Yorack to Elsa (1766–1767), also published in 1775 At the end of the sermon in Tristram he aliminated that, if this sample of Yorack's pulpit eloquence was liked, intimated that, if this sample of You'ck's pulpit eloquence was itsed,
"then ear now in this passession of the Sampers and much nooth may
they do it." Accordingly, when a second extinon of the first installment
of Trastraw was called for in three months, two wolumes of Sermoss
by Yorke were announced Although they had little or none of the
Steme's cleant-cleanted was far from being universally injured
by the molecorous freaks as a humoist. Loud Fauconberg presented
the nathor of Traitram Shandly with the prepetual caracy of Convoid

the author of Tratems Sheady with the perpetual curacy of Cowold To this new residence he went in high spirits with his success, "fully determined to write as hard as could be," seeing no reason why he should not gove the public two volumes of Shandysm every year and type the seed of the seed of the seed of the seed of France, and he came back after two and a half years very httle stronger. He was overgoed with his reception in Fars He contained the seed of of another set of sermons—more pronouncedly Shandean in their ec-

of another set of sermons—more pronouncedly Shandean in their ex-centracity—be quited England again in the summer of 1796, and trav-elled in Italy as far at Napies. The muth said and adsorts volume and the said of the This despatched, Sterne turned to a new project, The Sentimental Journey through France and Italy. Its plan admitted of any length that the author choose, but, after seeing the first two volumes through the press in the early months of 1768, Sterne's strength failted, and be due in his bologapa, at Old Bood street, London, March 18, three weeks

after the publication.

atter the publication.

An excellent citizen of Sterne's works, edited by George Saintsbury, was issued in sax volumes in 1894. STESICHORUS (c. 640-555 B.C.), Greek lyne poet, a native of Himera in Sicily, or of Mataurus, a Locrian colony in the south of Italy. The story of his being struck blind for slandering Helen and recovering his sight when he recanted is told by Plato among others. We possess about 30 fragments of his poems, none of them longer than six lines. They are written in the Doric dialect, them longer than six lines. They are written in the Doric dialect, with epic liennes; the metie is decipiled-tenchase. Briff as they are, they show us what Longinus meant by calling Steachorus "most like Homer"; they are full of epic granders, and have a stately sublimity of the stately sublimity of the stately sublimity of the stately sublimity. The stately sublimity of the stately sublimity

STETHOSCOPE, a medical instrument used in listening to the sounds produced in the heart, lungs and other organs. This is known as auscultation (q.v.), which is a means of physical examination used in the diagnosis of diseases, especially those of the heart and lungs. The single stethoscope is a straight wooden or metal tube with a small flattened bell, the surface of which is usually covered with ivory or bone at one end, which is placed against the body of the patient, and a large flat disk at the other end, for application to the ear of the observer. In the "binaural" stethoscope, which has the advantage of flexibility, the tube is divided above the bell into two flexible tubes which lead to both (F. L. A.)

STETTIN (Szczecin), Poland, formerly capital of the Prussian province of Pomerania, Germany, on the Oder, 17 mi above its entrance into the Stettiner Haff, 30 mi from the Baltic, 84 mi NE of Berlin by rail, and at the junction of lines to Stargard-Danzig and Kustrin-Breslau Pop (1946) 72,948; (1939) 268,915 Stettin is said to have existed as a Wendish settlement in the 9th century, but its first authentic appearance in history was in the 12th cen-tury, when it was known at Stedyn From the beginning of the 12th century to 1637 it was the residence of the dukes of Pomerania, one o whom gave it municipal lights in 1243 Alteady a leading centre of trade it entered the Hanseatic league in 1360. The Pomeraman dynasty became extinct in 1617, and in 1648 Stettin was ceded to Sweden In 1678 it was taken from Sweden by Frederick William, elector o Brandenburg, but it was restored in 1679, only, however, to be ceded to Plussia in 1720 by the Peace of Stockholm. It was fortified more strongly by Frederick the Great. Stettin was the bittipplace of the empress Catherine II of Russia.

STEUBENVILLE, a city of eastern Ohio, U.S., on the Ohio river, 40 mi. W. of Pittsburgh, Pa.; the county seat of Jefferson county. It is on federal highway 22 and is served by the Pennsylvania and the Nickel Plate railroads, motorbus and truck lines, river packets and barges. Two highway bridges span the Ohio. Pop. (1950) 35,872. The city lies on a plain 700 ft, above sea level, surrounded by hills rising 300-500 ft. higher, in a beautiful and fertile region containing rich deposits of coal, oil, gas, clay and building stone. The manufacturing industries are large and varied, including steel and steel products, paper products, heaters, bousehold uteralis, electrical parts, prefabricated houses, trailers, the plate products and back.

Steubenville was planned in 1797, immediately after the erection of

the county, on the site of Fort Steuben (built 1786 and named after Baron von Steuben) It was incorporated in 1805. The Steubenville Herald-Star, one of the oldest newspapers in the tristate district, was established in 1806

STEVENS, ALFRED (1823-1906), Belgian painter, was born on May 11, 1823, in Brussels, where he studied under F. norm on May 11, 1023, in Bussess, where he studied under r. Navez, director of the academy, who worked in the tradition of J. A. D. Ingres. Going to Paris in 1844, Stevens worked under C Roqueplan and at the École des Beaux-Arts, where Ingres was then professor. Stevens mainly worked, and from 1849 exhibited, in the French capital, which from the mid-1850s provided material for his pictures, usually conversation pieces and small informal full-length portraits of fashionable women set in Second Empire hôtels. In the elegant genre tradition of Gabriel Metsu, J E. Liotard and L L Boilly, they reflect neither largres' academism, Eugène Delacroix's romanticism nor Gustave Courbet's new realism 'typical are "L'Invi-tation" (late 1860s), "Les dermers jours de veuvage" (1870s, both in Brussels private collections) and "Le Sphyinx Parisien" (c. 1880). Stevens died in Paris on Aug 24, 1906

STEVENS, ALFRED GEORGE (1817-1875), English sculptor, was born on Dec 30, 1817, at Blandford, Dorset. He travelled in Italy, 1833-42, spending a year (1841-42) under Beitel Thorwaldsen (g.v.) in Rome In 1845-47 he taught at the new School of Design, Somerset house, London, and in 1850-52 designed cast-metal hearth furniture, stoves, etc., for Hoole and Company, Sheffield, some of which attracted attention at the 1851 Great exhibition In the 1857 competition for the Wellington monument in St. Paul's cathedral, London, he was placed sixth, though his design was the only one adapted to the nave arch under which the monument was to stand In 1852, however, he was given the commission and, despite vicissitudes, the complex marble structure the commission and, despite vicusistudes, the complex marine structure with its allegones and bronze equestina statue was nearly complete at his death (in Hampstead, May 1, 1875). For Dorchester house, Lon-don, he carried out decorations in 1838-01 (caryatid manthepiece and many drawings to Dorchester house and other piolects now in the Tate gallery, London), and these best display the new vigour he many drawings (on LOTChesser Mosses and State Spiley the new vigour has the gallery London), and these best estimates of the spile of t

STEVENS, HENRY (1819-1886), U.S. bibliographer, was born in Barnet, Vt., on Aug. 24, 1819. He studied at Middlebury college, Vermont, and graduated from Yale in 1843, teaching to pay his way and for a time acting as a government clerk. In this capacity he won the friendship of Col. Peter Force, who employed him to collect books, pamphlets and manuscripts for the American archives on his return to Yale and during his year at the Cambridge, Mass., law school. His commissions from Force and other collectors took him abroad, where he ransacked the European capitals for rare Americana for the Smithsonian institution, the Library of Congress and such private buyers as John Carter Brown and Jam At the suggestion of Sir Anthony Panzzi, the librarian of the British museum, he also supplied that institution with many American hooks

books. Strong that at Hamptess, London on Peb. 26, 285. Strong pile ninet mobile ablebenemit was his redemption of the Franklin manuscripts, which were finally disposed of to the U.S. government. He wrote Catalogue of the abricant Books in the Library of the British Museum (1865), Historical Nugaest, Bibliothica American of the British Museum (1865), Historical Nugaest, Bibliothica American on America (1869), Benjamine Franklin't Life and Writing's (1887), Recollections of Mr. James Leion. . and the Formation of His Library (1885)) and Thomas Harde's (1905) cidettly by his son, H N. Streng.

STEVENS, JOHN (1749-1838), U.S. inventor, was born in New York city in 1749, graduated from Columbia university in 1768, subsequently studied law and was admitted to the New 11 1700, SUDSEQUENTLY SELUCION AW SIGNAMS AGMITTED TO the New York bain 11771. In 1736 he becames a capitaln it the Revolutionary army, and later colonel of his own regiment. From 1737 to 1782 he served the treasurer of the state of New Jersey. In 1784 he built as home out what was then it is island of Broboten, subsequently, when

connected with the mainland, known as Stevens point, where he resided for more than half a century until his death on March 6, 1838. He purchased the ferry to New York and much of the main New Jersey shote Along the road leading to the ferry landing he began the development

The problem of safe and speedy transportation across the Hudson

The problem of safe and speedy transportation across the Hudson

In 1788 he built the first multitubular boiler on record for use in his marine ne dult the first multitudual police on record for use it als marine engines. In a desire to protect this invention he petitioned congress for a patent law, which he outlined, and which was passed as the Patent law of 1790, the foundation of the present patent system. He was the first to apply the principle of screw propulsion to navigation, building in 1802 a steamboat with two underwater propellers of screw type in the stern which successfully crossed the Hudson several times and the stem which successfully crossed the Hudson several times and failed only because the inefficient bioliers of that day could not generate enough power to make the screw device practical. He turned then which field the was a pomen: But a few days after Fullon's successful trail of the "Clermont" Stevens launched the "Phoenix," the engine of which was built by Stevens hamel, whereas that of the "Clermont" was imported from England Fullon having icceived a monopoly grant of analystation rights on the Hudson, Stevens sent the "Phoenix" by sea to Philadelphia, the first voyage of a steamship on ocean waters. by sea to Philadelphu, the first voyage of a steamship on ocean waters. Sevenes was also intersected in railways, writing in 1822 a paraphile sevenes was also interested in railways, writing in 1822 a paraphile ways and Steam Carriages over Caul Mesugation. On Feb 6, 1815, the ways and Steam Carriages over Caul Mesugation. On Feb 6, 1815, the solution the first railway chatter granted in America for a railway between the Delaware and Raritan rivers, but it was not until 1830 that formed the Canadica and Ambor Railway company and not until by his sons Robert L. Stevens (qv. v) and Edwin A. Stevens (24) and Edwin A. Stevens. See A. D. Turnbull, John Stevens, A. American Record (1928); J. E. Watkins, Biographical Shetches of John Stevens, Robert L. Stevens (1848).

STEVENS, ROBERT LIVINGSTON (1787-1856), U.S. mechanical engineer, was born at New York city on Oct 18, 1787. the son of John Stevens (q, v), whose mechanical ability he inherited. Whereas the father spent most of his thought on the improve-ment of motive power and machinery of steamboats, the son made ment of motive power and machinery of steamboats, the son made many advances in construction, strengthening hulls, reducing weight, distributing stram and improving the lines to gain speed. He designed the strain of the strain of the strain of the strain of the first of Hudson river steames to go from Albany to New York during daylight, with this steamer and the "North America," the Stevens family in-sugarated a day line on the Hudson. In 1821 he built the ferryboat "Hobboan" on modern lines and introduced the pilot slip which directed

the boat's entrance to the landing place.

In 1830 he was made first president of the Camden and Ambov rail-In 18,0 he was made first president of the Camden and Amboy raile-way and went to England to Inspect equipment already in use the On the outward voyage he designed the "T" rail with a broad base, long known as the Stevens or American rail and now universally used He contracted in England for 500 tons of such rails, the first made, and exclude the such as the such as the such as the such as the such exclude the such as the such as the famous "John Bull" which he brought to the U.S. on his return and which is now in the Smit-sonian institution He made many improvements on railway locomo-tives, introducing the pilot truck in 18,34, the begue truck shortly after-ior order to promote adhesion to the rails and drawing power. When order to promote adhesion to the rails and drawing power. When recorded to the such as the such as the such as the such as the recorded to the such as the such as the such as the such as the recorder to the such all crossorses with broken stone and served between stone blocks could not be furmished fast enough for his readede he recorred to log laid crossives with broken stone and graved between and discovered that he had found a bed more serviceable and commented that the had found a bed more serviceable and compared to the state of th

Stevens, Edwin A. Stevens (1893).

STEVENS, THADDEUS (1792-1868), U. S. political leader, was born in Danville, Vi., April 4, 1792. He graduated from Dartmouth college in 1814, moved to York, Pa., was admitted to the bar (in Maryland) and for 15 years practised at Gettyaburg, Pa. He frequently appeared in behalf of fugitive shores before the Penalest Parameter of the Penalest Parameter of the Penalest Parameter of the Parameter

from the joint committee what became the 14th amendment, and also the Reconstruction act of Feb 6, 1867 He advocated the Freedmen's bureau bills and the Tenure of Office act, and went beyond congress in nureau ones and the l'enure of Omce act, and went beyond congress in favouring the confiscation of property in Confederate states. He led congress in the struggle with Pres Andrew Johnson, reported the impeachment resolution and was chairman of the committee appointed to drait the articles of impeachment. He died at Washington, D.C.,

STEVENSON, ADLAI EWING (1835-1914), vice-president of the United States, 1893-97, was born in Christian county uen, or the Onifen States, 1893-97, was born in Christian Country, Ky, on Oct 23, 1835. He studied at Centre college, read law and commenced practice at Metamora, Ill. He was a member of the 44th Grover Cleveland's first administration. He was given the Democratic nomination for vice-president in 1892 so that the west should be represented on the ticket which Cleveland, an exsterner, headed. In 1897 he was chairman of a commission sent to Europe to work for international bimetallism He was again nominated for vice-president international himetalism He was again hominated for vice-pressurer on the ticket with W J Bryan in 1900, and in 1908 he was unsuccessful as the Democratic candidate for governor of illinois He wrote a pleasant book of reminiscences, Something of Men I Have Known STEVENSON, ADLAI EWING (1900—), US lawyer

and public official, was born in Los Angeles, Calif., on Feb 5, 1900, the son of Lewis Green Stevenson, secretary of state of Illinois, 1914-16, and grandson of Adlai Ewing Stevenson (q.v), vice-president

1914-16, and grantson of ratins awaig sections (1917).

of the U.S., 1893-07] public schools in Bloomington, Ill, and Choate school, Wallingford, Conn., and in 1912 was graduated from Princeton auliversity, Princeton, M.J. In 1918 he served as an appendice seamed in the U.S., and an appendice seamed in the U.S., and a served. two years, he was assistant managing editor of the Bloomington Dasly

He later served in the Agricultural Adjustment administration in Washington, D. C., and was assistant to the secretary of the navy, 1941-44. In 1945 Stevenson headed a Fordgn Economic administration mission to Italy, and in 1944 he was a member of a war department mission to Europe. He 1944 he was a member of a war department misson to Europe. He became assistant to the sectorary of state in 1943 and was adviser to the US chegation at the United Nations Conference on International US delegation at the United Nations Conference on International US delegation at the UN, general assembly, New York city, 1946-497, in 1948 the conference of the Property of the United National US delegation at the UN general assembly, New York city, 1946-497, in 1948 the UN greater of the UN great of the UN g

was the only son of Alan Stevenson, partner in a West Indian house in Glasgow, and was born in that city on June 8, 1772. He was educated at Anderson's college, Glasgow, and at Edinburgh university. He assisted his stepfather, Thomas Smith, in lighthouse schemes, and at 19 was sent to superintend the erection of a lighthouse on the island of Little Cumbrae Subsequently tion of a lighthouse on the island of Little Cumbrae Subsequently he succeeded Sunth as engineer to the Commissioner of Northern Lighthouses, and from 1707 to 1843 he designed and built a large number of lighthouses, the most important being had on the Bell Bished, from which the admirably sailing directions for the coasts of Great Britain and Iriend were prepared. Stevenson published an Account of the Bell Rock Lighthouse in 1824, contributed to the Encyclopiada Britainsia, and worter various papers read before learned societies. Whe dent at Eduburgh on July 1850.

THE WINDOWN, ACHERN LOUIS BA. FOUR. (1850–1872 WINDOWN, ACHERN LOUIS BA. FOUR. (1850–1872 WINDOWN, ACHERN LOUIS BA. FOUR.

1894), British essayist, novelist and poet, was the only child of Thomas Stevenson, civil engineer, and his wife, Margaret Isabella Balfour. He was born at 8 Howard Place, Edinburgh, on Nov. 13, 1850. He suffered from infancy from great fragility of health. and nearly died in 1858 of gastric fever, which left much constitutional weakness behind it. He went to school, mainly in Edinburgh, from 1858 to 1867. As his health improved it was hoped that he would be able to adopt the family profession of civil engineering, and in 1868 he went to Anstruther and then cvil eignteering, and in 1808 ne went to Anstruther and then to Wick as a pull engineer. In 1871 he had so first andwared as to receive the silver medial of the Ediniungs Society of Arts for a paper except the silver medial of the Ediniungs Society of Arts for a paper except the silver properties and the silver properties of the templeor's life, it straineds his physical endurance too much, and in 1871 the was called in 4875. In 2878, 3-first river Sidney-Carlier, but was relicatively exchanged for sixty at the Ediniuntly har, to which he was called in 4875. In 2878, 3-first river Sidney-Carlier, but was to prove the closes of the driends and gard also the loval and admirable editor of his works and his correspondence

He was now labouring, with extreme assiduity, to ground himself in the forms and habits of literary style. In 1875 appeared, anony-mously, his Appeal to the Clergy of the Church of Scotland, and in that year he ma de the first of many visits to the forest of Fontainebleau, that year he made the first of many visits to the lorest of Fontanebleau, Meanwhile at Mentone in the winter of 1873-1874, he had grown in mind under the shadow of extreme physical weakness, and in the following spring began to contribute essays of high originality to one or two periodicals, of which the Cornthil, then edited by Leshe Stephen, was at first the most important. Stevenson made no attempt to was at first the most important. Sevension made no attempt to practise at the bar, and the next years were spent in wanderings in France, Geimany and Scotland. Records of these journeys were published as An Inland Voyage (1878), and as Travels with a Donkey in the Cevennes (1879). During these four years Stevenson's health, which was always bettered by hie out of doors, gave him little trouble At Fontainebleau in 1876 Stevenson had met Mrs Osbouine, the lady who atterward became his wise, she returned to her home in California in 1878, and in August of the following year, alarmed at news of her illness, Stevenson hurriedly crossed the Atlantic He travelled, from lack of means, as a steerage passenger and then as an emigrant, and in December, after hardships which seriously affected his health, he arrived in San Francisco. In May 1880 he married, and moved to the rived in San Francisco In May 1880 he married, and moved to the desolate mining camp which he has described in *The Silverado Squatters*. Some of his most pognant and most enchanting letters were written during this romantic period of his life. In the autumn of 1880 he returned to Scotland, with his wife and stepson, who were received at once into the Edinburgh household of his patents. But the condition of his health continued to be very alarming, and they went almost immediately to Davos, where he remained until the spring of almost immediately to Davos, where he remained that the spring or 1881. In this year was published Virginibus pherisque, the eathest collection of Stevenson's essays. He spent the summer months in Scotland, writing articles, poems, and above all his first romance, The Sea-Cook, afterward known as Treasure Island, but he was driven back to Davos in October In 1882 appeared Familiar Studies of Men and Books and New Arabian Nights His two winters at Davos had done him some good, but his summers in Scotland invariably unded the benefit He therefore determined to reside wholly in the south of Europe, and in the autumn of 1882 he settled near Marsellles This did Europe, and in the autumn of 18% he settled near Marseille: This did not suit him, but from March 1881; to July 1884, he was at home at a charming house called La Solitude, above Hyères, this was in many ways to be the happest station in the pannil and hurrying pilerimage ways to be the happest station in the pannil and hurrying pilerimage and also the more important Treasure Island, which made Stevenson for the first time a popular writer He planned a vast amount of work, but his schemes were all frustrated in January 1884, by the most serious lilness from which he had yet suffered. The attack was followed by long prostration and incapacity for work, and by continued relapses in July he was brought back to England, and from this time mental In July Be was orought oack to Enguind, and Itom tims time until August 1887 Stevenson's home was at Bournemouth. In 1885 be pub-lashed, after long indecision, his volume of poems, A Chid?: Garden of Verset, an inferior story, The Body Statcher, and that admirable romance, Prince Otto, in which the peculiar quality of Stevenson's style was displayed at its highest. He also collaborated with W. E. Henley in some plays, Beau Austin, Admiral Guinea and Robert Macaire Early in 1886 he struck the public taste with precision in his wild symbolic tale of The Strange Case of Dr. Jekyll and Mr Hyde. In the summer of the same year he published Kidnapped, which had been written at Bournemouth

Stevenson printed privately as a pamphlet, in June 1887, a brief and touching sketch of his father In July he published his volume of lyrical poems called *Underwoods*. The ties which bound him to Englyrical poems called Underwoods. Ine tres winch bound min to oug-land were now severed, and he determined to remove to another hem-sphere. He sailed from London, with his wife, mother and stepson, for New York on Aug. 17, 1887. He never set foot in Europe again. His memoir of his friend Professor Fleeming Jenkin was published soon. This memory of his memo reviessor revening Jenkin was puomsene soon after his departure. After resting at Newport, he went for the winter to be under the care of a physician at Saranac Lake in the Adirondacks. In this retract he was very quest, and steadily active with his pen, writing both the greater part of the Master of Ballanarea and many of his finest later essays. He had undertaken to contribute a monthly essay writing both the greater part of the Mastier of Ballastirae and many of its finest later easies. He had undertaken to contribute a monthly essay to Saribner's Magazine, and these essays, twelve in number, were publication of the Mastine and the Saribner's Magazine, and these essays, twelve in number, were publicated and the Mastine and the Saribner's Magazine, and the season of the Mastine the Saribner's Magazine, and the season as the Saribner's Mastine season as the Saribner's Mastine Saribner's Mast months' cruising found themselves at Samoa, where he landed for the first time about Christmas day 1889 On this occasion, however, though strongly drawn to the beautiful island, he stayed not longer though strongly drawn to the deathful island, he wayed not longer than are weeks, and proceeded to Sydney, where eath in 1890, he pub-lished, in a blaze of tighteous anger, his father Damien an Open Letter to the Rev Dr Hyde of Honolulu, in vandacation of the memory of Father Damien and his work among the lepers of the Pacific. while his volume of Ballads was published in London

while his volume or bancar was punished in London
The last four years of his unquiet hir ever spent at Samoa, in circumstances of such health and vigour as he had never previously enjoyed, and in surroundings singularly picturesque. In November 1850
he made his abode at Valluna, where he took a small barrack of a me made his adoute at vacations, where he uson a small barrack of a wooden box 500 ft above the sea, and began to build himself a large house close by The natives gave him the name of Tustala He took up the cause of the deposed king Matafa with extreme ardour, and he wrote a book, A Footnote to History Eight Years of Trouble in Samoa (1892), in the endeavout to win over British sympathy to his native friends In the autumn of this year he received a visit at Valima from the countess of Jersey, in company with whom and some others he wrote the burlesque extravagance in prose and verse, called An Object of Pity, privately printed in 1893 at Sydney Whenever the cultivation of his estate and the vigorous championship of his Samoan retainers gave him the leisure, Stevenson was during these years almost wholly occupied in writing iomances of Scottish life The Wrecker, an adventurous tale of American life, which mainly belonged to an earlier time, was written in collaboration with Lloyd Osbourne and finally published in 1892, and toward the close of that very eventful namy phonished in 1692, and toward the close of that very eventum and busy year he began The Justice Cleik, alterward Weir of Hermiston In 1893 Stevenson published the Scottish romance of Castriona, written as a sequel to Kudnapped, and the three tales illustrative of Pacific ocean character, Island, Nights' Entertainments But in 1893 the uniform good fortune which had attended the Steven-sons since their settlement in Samoa began to be disturbed. The whole family at Valima became ill, and the final subjugation of his protégé iamiy at vaiima oceame ii, and the final suguigation of his protege Matatata, and the destruction of his party in Samoan politics, deeply distressed and discouraged Stevenson. In a series of letters to The Times he exposed the policy of Chef Justice Cedercrant, and the president of the council, Baron Senfit. He so influenced public opinion that both were removed from office. In the autumn of that year he went for a change of scene to the Sandwich Islands, but was taken ill there, and was only too glad to return to Samoa In 1894 he was greatly cheered by the plan, suggested by friends in England and carried out by them with the greatest energy, of the noble collection of his works in 28 volumes, since known as the Edinburgh edition. In Sept. 1894 was published The Ebb Trde, the latest of his books which he saw through the press Of Stevenson's daily avocations, and of the temper of his mind through these years of romantic exile, a clear idea may be obtained by the posthumous Vailima Letters, edited by Sidney Colvin obtained by the postnumous Valima Letters, cutted by Statey Colvin in 1895. Through 1894, he was engaged in compoung two romances, neither of which he lived to complete. He was dictating Weir of Hermitton, apparently in his usual health, on the day he died. This was Dec. 3, 1894, he was gaily talking on the verandiah of his house the Valima when he had a stroke of apoplexy, from which he never recovered consciousness, and passed away painlessly in the course of the evening His body was carried next day by 6c sturdy Samoans, who acknowledged Stevenson as their chief, to the summit of the precipitous peak of Vaea, where he had wished to be buried, with the Pacific ocean at his feet.

The charm of the personal character of Stevenson and the romantic vicissitudes of his life are so predominant in the minds of all who knew visisatudes of his life are so predominant in the mands of all who have him, or lived varish earshot of his legand, that they made the ultimate position which he will take in the history of English interature some-man of letters in his generation is similated, and the acknowledged fastmation of his character was deepened, and was extended over an oxtremely wide circle of readers, by the publication in 1899 of his Letters, which have subdused even those who were rebellious to the entertainment of in books. It is therefore from the point of whee of its charm that the genius of Stevenson must be approached, and in this respect there was between himself and his books, his manners and his

respect mere was between nimeer and ms books, ms manners and ms style, his practice and his theory, a very unusual hamony. The personal appearance of Stevenson has often been described he was tall, extremely thin, dark-haired, restless, compelling attention with the lustre of his wonderful brown eyes. Whatever may be the ultimate order of reputation among his various books, or whatever posterity may ultimately see fit to ordain as regards the popularity of any of them, it is difficult to believe that the time will ever come in which Stevenson will not be remembered as the most beloved of the writers of that age which he did so much to cheer and stimulate

(E, G, X.)

R. L. Stevenson's other works include: Memories and Portraits (1887); The Merry Men and other Taies and Fables (1887); The Stevenson's other Taies and Fables (1887); The He Flaux, with other Memories and Essays (1894); and the post-humous works, Songs of Traves and Essays (1894); and the post-humous works, Songs of Traves and Essays (1894); St. testes (1895), completed by Gr. A. T. Quiller Coults, A. Steenenson Medical (1895), and the Equation (1895) (1895). See the Letters of Stevenson to his

STEVENSON, WILLIAM (d. 1575), probable author of the English comedy Gammer Gurton's Needle, was born at Hunwick, Durham, matriculated in 1546, took his M. A. degree in 1553, and became B D in 1560 Stevenson was a fellow of Christ's college, Cambridge, from 1551 to 1554 and from 1559 to 1561. He was made a prebendary of Dunham in 1560-61 and died in 1575 Gammer Gurton's Needle is the second extant English comedy, properly so-called William Stevenson is known to have written a play which was acted at Christ's college in 1553-54; and in the accounts of Christ's college for 1550-60 is the entry, "Spent at Mr Stevenson's plaie, 5s." Contemporary Punitan writers in the Marprelate tracts allude to Dr. John Bridges, dean of Salisbury, author of A Defence of the Government of the Church of England, as the reputed author of Gammer Gurton's Needle, but he obviously could not be properly described as "Mr S" He took his M.A. degree at Pembroke college, Cambridge, in 1560. He may possibly have been a coadjutor.

unings, in 1905. He may possinly mave usen a cosquitor.

STEVENS POINT, a city of central Wisconsin, U.S., on the Wisconsin and Plover rivers; county seat of Portage county. It is on federal highways 10 and 51, and is served by the Green Bay and Western and the Soo Line railways. Pop. in 1950 was 16,564. The village was incorporated in 1858. Manufactures include paper, lumber, furniture and leather.

STEVENSTON, manufacturing town and parish of Ayrshue, Scotland. Pop. (1951) 9,392. It is situated about 1 mi. from Saltcoats on the coast of the Firth of Clyde, 29 mi. S W. of Glasgow by rail. There are coal mines, large ironworks and foundlies, and along the shore, the works of Nobel's Explosives company. Pop. of civil parish (1951) 13,695.

STEVINUS, SIMON (1548-1620), Dutch mathematician, was born in 1548 at Bruges and died in 1620 at The Hague or in Leyden. He was director of the "waterstaet," and afterwards quartermaster-general. Stevinus was known to his contemporaries by his military methods and inventions; he invented defence by a system of sluices which was of great importance in the Netherlands. He also invented a carriage with sails which was used on the seashore and carried 26 passengers.

In his Statics and Hydrostatics (Leyden, 1586) he enunciated the important theorem of the triangle of forces. This gave a new impetus to the study of statics, which had previously been founded on the theory of the lever. He discovered the hydrostatic paradox that the downward pressure of a liquid is independent of the shape of the vessel, and depends only on its height and base.

In 1586 he published a pamphlet of a few pages, the French translation of which is entitled La Disme enseignant facilement expédier par Nombres Entiers sans rompuz tous Comptes se rencontrans aux Affaires des Hommes. In this he treated decimal fractions. Decimal fractions and fractions had been employed for the extraction of square roots some five centuries before his time. but nobody before Stevinus established their daily use. He declared the universal introduction of decimal coinage, measures and weights to be only a question of time. His notation is rather unwieldy. He printed little circles round the exponents of the different powers of one-tenth. For instance, 237 1000 was printed 237 @ 5 @ 7 @ 8 @, and the fact that Stevinus meant those encircled numerals to denote mere exponents is evident from his James Stewart, the black knight of Lorn, by Joan or Joanna, employing the same sign for powers of algebraic quantities, eg, widow of King James I From Murdoch, duke of Albany, were 9 @ -14 @ 9-6 @ -5 to denote gs'-142"+6x-5

A number of his writings were translated into Latin by W Snellius There are two complete editions in French of his works (Leyden, 1608 and 1634) by Albert Girard See Steichen, Vice et travaux de Simon Steum (Blussels, 1846), M Cantor, Geschichte der Mathematik

STEWART, STUART or STEUART, the surname of a family which inherited the Scottish and ultimately the English crown Their descent is traced to a Breton immigrant, Alan the son of Flaald, which Flaald was a brother of Alan, steward (or seneschal) of Dol in Brittany This elder Alan, whose name occurs in Breton documents before 1080, went on crusade in 1097, and was apparently succeeded by his brother Flaald, whose son, the younger Alan, enjoyed the favour of Henry I., who bestowed on him Mileham and its barony in Norfolk, where he founded Sporle Priory By the daughter of Ernulf de Hesdin (in Picardy), a Domesday baron, he was father of at least three sons. Jordan, who succeeded to the family office of steward of Dol: William. who inherited Mileham and other estates in England, and who founded the great baronial house of Fitz Alan (afterwards earls of Arundel); and Walter, who was made by David I. steward (dapter) or seneschal of Scotland The Scottish king conferred on Walter various lands in Renfrewshire, including Paisley, where he founded the abbey in 1163 Walter, his grandson, third steward, was appointed by Alexander II. justiciary of Scotland, and, dying in 1246, left four sons and three daughters. The third son, Walter, obtained by marriage the earldom of Menteith, which ultimately came by marriage to Robert, duke of Albany, son of Robert II. Alexander, fourth steward, the eldest son of Walter, third steward, inherited by his marriage with Jean, granddaughter of Somerled, the islands of Bute and Arran, and on Oct. 2 1263 led the Scots against Haakon IV, king of Norway, at Largs He had two sons, James and John The latter, who commanded the men of Bute at the battle of Falkirk in 1298, had seven sons: (1) Sir Alexander, whose grandson George became in 1389 earl of Angus, the title afterwards passing in the female line to the Douglases, and in 1761 to the duke of Hamilton; (2) Sir Alan of Dreghorn, ancestor of the earls and dukes of Lennox, from whom Lord Darnley, husband of Queen Mary, and also Lady Arabella Stuart, were descended; (3) Sir Walter, who obtained the barony of Garlies, Wigtownshire, from his uncle John Randolph, earl of Moray, and was the ancestor of the earls of Galloway, younger branches of the family being the Stewarts of Tonderghie, Wigtownshire, and also those of Physgill and Glenturk in the same county; (4) Sir James, who fell at Dupplin in 1332, ancestor of the lords of Lorn, on whose descendants were conferred at different periods the earldoms of Athole, Buchan and Traquair, and who were also the progenitors of the Stewarts of Appin, Argyllshire, and of Grandtully, Perthshire; (5) Sir John, killed at Halidon Hill in 1333; (6) Sir Hugh, who fought under Edward Bruce in Ireland, and (7) Sir Robert of Daldowie. ancestor of the Stewarts of Allanton and of Coltness James Stewart, the elder son of Alexander, fourth steward, succeeded his father in 1283, and, after distinguishing himself in the wars of Wallace and of Bruce, died in 1309. His son Walter, sixth steward, who had joint command with Sir James Douglas of the left wing at the battle of Bannockburn, married Marjory, daughter of Robert the Bruce, and during the latter's absence in Ireland was entrusted with the government of the kingdom. He died in 1326, leaving an only son, who as Robert II. ascended the throne of Scotland in 1371. Sir Alexander Stewart, earl of Buchan, fourth son of Robert II, who earned by his ferocity the title of the "Wolf of Badenoch," inherited by his wife the earldom of Ross, but died without legitimate issue, although from his illegitimate offspring were descended the Stewarts of Belladrum, of Athole, of Garth, of Urrard and of St. Fort. On the death of the "Wolf of Badenoch" the earldom of Buchan passed to his brother Robert, duke of Albany, also earl of Fife and earl of Menteith, but these earldoms were forfeited on the execution of his son Murdoch in 1425, the earldom of Buchan again, however, coming

James Stewart, the black knight of Lorn, by Joan or Joanna, widow of King James I From Murdoch, duke of Albany, were descended the Stewarts of Ardvoirlich and other families of the name in Perthshire, and also the Stuarts of Inchbreck and Laithers. Aberdeenshire From a natural son of Robert II were descended the Steuarts of Dalguise, Perthshire, and from a natural son of Robert III the Shaw Stewarts of Blackhall and Greenock The direct male line of the royal family terminated with the death of James V. in 1542, whose daughter Mary was the first to adopt the spelling "Stuart" Mary was succeeded in her lifetime in 1567 by her only son James VI, who through his father Lord Darnley was also head of the second branch, there being no surviving male issue of the family from progenitors later than Robert II. In James V, son of James IV. by Margaret, daughter of Henry VII, the claims of Margaret's descendants became merged in the Scottish line, and on the death of Queen Elizabeth of England, the last surviving descendant of Henry VIII, James VI of Scot-land, lineally the nearest heir, was proclaimed king of England, in accordance with the arrangements made by Lord Burghley and Elizabeth's other advisers The accession of James was, however, contrary to the will of Henry VIII, which favoured the heirs of his younger sister Mary, wife of Charles Brandon, duke of Suffolk

By the usurpation of Cromwell the Stuarts were excluded from the throne from the defeat of Charles I at Naseby in 1645 until the restoration of his son Charles II on May 8, 1660 On the death of Charles II without issue in 1685, his brother James, duke of York, ascended the throne as James II., but he so alienated the sympathies of the nation by his unconstitutional efforts to further the Roman Catholic religion that an invitation was sent to the prince of Orange to come "to the rescue of the laws and religion of England" Next to the son of James II, still an infant under his father's control, Mary, princess of Orange, elder daughter of James II, had the strongest claim to the crown; but the claims of the prince of Orange also, even apart from his marriage, were not very remote, since he was the son of Mary, eldest daughter of Charles I. The marriage had strengthened the claims of both, and they were proclaimed joint sovereigns of England on Feb. 12, 1689, Scotland following the example of England on April 11. They left no issue, and the Act of Settlement, passed in 1701, excluding Roman Catholics from the throne, secured the succession to Anne, second daughter of James II., and on her death without issue (1714) to the Protestant house of Hanover descended from the princess Elizabeth, daughter of James I, wife of Frederick V., count palatine of the Rhine George, elector of Hanover, eldest son of Sophia (youngest child of the princess Elizabeth), and Ernest, elector of Brunswick-Lüneburg, or Hanover, became sovereign of Great Britain and Ireland The female issue of James II. ended with the death of Anne. James, called James III by the Jacobites and the Old Pretender by the Hanoverians, had two sons-Charles Edward, the Young Pretender, who died without legitimate issue in 1780, and Henry Stuart, titular duke of York, commonly called Cardinal York, on whose death in 1807 the male line of James II. came to an end. Henry was also the last descendant in the lineal male line of any of the crowned heads of the race, so far as either England or Scotland was concerned In the female line, however, there are among the descendants of James I representatives of the royal Stuarts who are senior to the house of Hanover, for Philip, duke of Orleans (brother of Louis XIV.), married, as his first wife, Henrietta, daughter of Charles I., and, as his second, Charlotte, granddaughter and heiress of the princess Elizabeth (daughter of James I ). By the former, through their daughter, the queen of Sardinia, he was ancestor, among others, of the princess Maria Theresa of Bavaria, who in 1910 was "heir of line" of the house of Stuart, her eldest son, Prince Rupert, being at that time heir to the throne of Bavaria.

STEWART, SIR DONALD MARTIN (1824-1900). British field marshal, son of Robert Stewart of Forres, Elginshire, was born at Mount Pleasant, near Forres, on March 1, 1824 He entered the Bengal army in 1840, and served in 1854 and 1855 in the frontier expeditions against the Mohmands, and Afridis Aka and Bari Khel (medal and clasp) In the Indian Mutmy in 1857 Stewart, after a famous ride from Agra to Delhi with despatches, served on the staff at the siege and capture of Delhi and Lucknow, and afterwards through the campaign in Rohilkhand For nine years he was assistant and deputy-adjutantgeneral of the Bengal army, commanded the Bengal brigade in the Abyssinian expedition in 1867, and became a major-general in 1868 He reorganized the penal settlement of the Andaman Islands, where he was commandant when Lord Mayo was assassinated, and, after holding the Lahore command, was promoted heutenant-general in 1877, and commanded the Kandahar field force in the Afghan War in 1878. On hearing of the Maiwand disaster he despatched Roberts with a division on his celebrated march from Kabul to Kandahar, and himself led the rest of the army back to India by the Khyber Pass. Promoted general in 1881, he was for five years commander-in-chief in India, and afterwards member of the council of the secretary of state for India until his death. He was promoted to be field marshal in 1894, and appointed governor of Chelsea Hospital in 1895. He died at Algiers on March 26, 1900.

See G R. Elsmie, Sir Donald Stewart (1903).

STEWART, DUGALD (1753-1828), Scottish philosopher, was born in Edinburgh on Nov. 22, 1753 His father, Matthew Stewart (1715-1785), was professor of mathematics in the university of Edinburgh (1747-1772) Dugald Stewart was educated at Edinburgh and Glasgow. At 19 he acted as substitute for his father in the chair of mathematics at Edinburgh. From 1785 to 1820 he was professor of moral philosophy in the university, though he retired from the active duties of the chair after the death (1809) of his second son, which was a great blow to him He died at Edinburgh on June 11, 1828.

Stewart's principal work is Elements of the Philosophy of the Human Mind (3 vols 1792, 1814, 1827). He also wrote Philosophical Essays (1810), and The Philosophy of the Active and Moral Powers (1828). His philosophical views are mainly the

reproduction of those of his master Reid

STEWART, SIR HERBERT (1843-1885), British soldier, born on June 30, 1843, at Sparsholt, Hampshire, was educated at Winchester and entered the army in 1863. Returning from service in India in 1873, he entered the staff college and the Inner Temple. He served in South Africa in the Zulu War and against Sikukuni, and was present at Majuba (1881), where he was made prisoner and was present at Majuna (1997), where the mas made present for a month. In Aug. 1882 he was placed on the staff of the cavalry division in Egypt, and took possession of Cairo after Tel-el-Kebir (Sept. 13, 1882). In 1884 he commanded the cavalry under Sir Gerald Graham at Suakin. For his services in Egypt he was made KCB, and was assistant adjutant and Q.M.G. in the south-eastern district in England (April-Sept. 1884). He then joined the expedition for the relief of Khartoum, and commanded the relief column sent by Lord Wolseley across the desert of Metemma. On Jan. 17, 1885, he repulsed an enemy charge near Abu Klea. He was promoted major-general, but died on the way back from Khartoum to Korti, on Feb. 16, 1885, and was buried

near the wells of Jakdul.

STEWART, WILLIAM (c. 1480-c. 1550), Scottish poet and translator, descendant of one of the illegitimate sons of Alexander Stewart, earl of Buchan, the "Wolf of Badenoch," was a

hanger-on at the court of James V Portions of his minor verse are preserved in the Bannatyne and Maitland Folio MSS. His chief work is a metrical translation of Hector Boece's History, in obedience to the command of James V, who entrusted Bellenden with its translation into Scots prose

Stewart's version remained in ms till 1858, when it was edited by W Turnbull for the "Rolls Series" (3 vols) The ms is now in the library of the university of Cambridge

STEWART, SIR WILLIAM (c 1540-c 1605), Scottish politician, began life as a soldier in the Netherlands, where he became a colonel In 1582 he was in Scotland, where James VI made him captain of his guard Having visited the English court in the king's interest in 1583, Stewart helped to free James from Wilham Ruthven, earl of Gowne, and to restore James Stewart, earl of Arran, to power, he was made a privy councillor and for a time assisted Arran to govern Scotland In 1584 he captured Gowrie at Dundee In 1594 he was knighted and was given lands at Houston He died before 1606

STEWART, WILLIAM DOWNIE (1878-1949), New Zealand politician and publicist, was born at Dunedin on July 29, 1878 In 1914 he entered parliament as member for Dunedin West, holding this seat from 1919 to 1935 after his political career had been interrupted by a period of war service with the Otago regiment in 1916-17 He was minister of customs 1921-28, of internal affairs 1921-24, of industries and commerce 1923-26, of finance 1926-28 and 1931-33, and attorney-general and acting prime minister in 1926 He was joint author (with J E. Le Rossignol) of State Socialism in New Zealand (1910). He died at

Dunedin, NZ, Sept. 29, 1949. STEYN, MARTINUS THEUNIS (1857-1916), last president of the Orange Free State, was born at Winburg in that State on Oct. 2, 1857 He was a student in Holland and later in England at the Inner Temple, and was called to the English bar in Nov. 1882 After his return to South Africa he practised as a barrister at Bloemfontein, and in 1889 was appointed state attornev of the Free State. A few months afterwards he became second pusne judge, and in 1893 first pusne judge of the high court. His decisions won him a reputation for ability and sound judgment In 1895, upon the resignation of President F. W. Reitz, Steyn was the candidate of the pan-Dutch party for the vacant post. The election resulted (Feb 1896) in a decisive victory for Steyn As president he linked the fortunes of his State with those of the Transvaal, a policy which led to the extinction of the republic. He took part in the peace negotiations at Klerksdorp in April 1902, but was prevented by illness from signing the instrument of surrender at Pretoria on May 31 In 1908-1909 he was vice-president of the Closer Union Convention, where he showed a conciliatory attitude

STEYNING (sten'ning), town in Sussex, England, 12 mi W N.W. of Brighton by a branch of the S.R. Pop. (1931) 1,885. The church of St. Andrew retains a series of Norman pier-arches in the nave. The Anglo-Saxon church of Stevning mentioned in Domesday is attributed to St. Cuthman, who is said to have settled here before the oth century, and whose shrine became a resort for pilgrims. In 1086 Steyning was a thriving port, with a market, a mint and two churches. Its decay began in the 14th century owing to the recession of the sea, and it received another blow in the suppression of its priory by Henry IV.

STEYR, a town in Upper Austria at the junction of the Steyr with the Enns, seized by Germany in 1938. It is an old town, dominated by a 10th century castle. Two important new suburbs, Steyrdorf and Ennsdorf, lie across the streams. Steyr is a centre

of the iron and steel industry. Pop. (1939) 44,821.

STIBNITE, a mineral consisting of antimony sulphide, Sb<sub>8</sub>S<sub>8</sub>, occurring as bladed or acicular orthorhombic crystals; an important ore of antimony. It was mentioned by Dioscorides and Pliny under the names stimmi, stibi and platyophthalmon (πλατυόφθαλμον); the last name refers to the use which the ancients made of the powdered mineral for darkening the eyebrows to increase the apparent size of the eyes. The Arabic name al-kohl (now strangely corrupted to alcohol) had reference to member of the university of St. Andrews. He was in orders, and a the same use. Antimonite is also a common name for this species.

The crystals are prismatic in habit, deeply furrowed longitudinally, and usually terminated by acute pyramidal planes There is a perfect cleavage (O10) parallel to the length of the crystals, and the basal plane (001) is a plane of gliding, the latter gives rise to very characteristic transverse striations or nicks on the cleavage surfaces of crystals which have been bent The colour is lead-grey, and the lustre metallic and brilliant, crystals become dull on prolonged exposure to light Cleavage flakes of extreme thinness transmit a small amount of red light, but are more transparent for heat rays. The mineral is quite soft (H=2), and has a specific gravity of 46 Stibnite occurs with quartz in beds and veins in gneisses and schists, or with blende, galena, etc., in metalliferous veins. Magnificent groups of brilhant crystals, up to 20 in in length, were formerly abundant in the antimony mine of Ichinokawa, on Shikoku island, Japan Large, but dull, crystals have also been found at Lubilhac in Haute-Loire, France Prismatic and acicular crystals often penetrating tabular crystals of barytes, are common at Baia Sprie in Rumania (formerly Felsőbánya, Hungary). (L. I. S)

STICK-INSECT, an insect of the family Phasmatidae (see ORTHOPTERA), so named because of a resemblance to twigs of trees and shrubs, upon which most phasmids live and feed body and legs are long and slender, and the protective resemblance to twigs is enhanced by the usually brown, gray or green coloration and the immobile attitudes assumed. Some species are further protected by an armature of sharp spines. Many are wingless; when winged the tegmina are short, but the hind wings are often large and beautifully coloured, though usually kept folded over the abdomen. As in the leaf-insects (q.v), to which phasmids are closely allied, the eggs closely resemble seeds. Stickinsects attain their largest size and greatest profusion of species in the tropics, one Australian species, Palophus tstan, reaching a length of 10 in. A few smaller forms occur in southern Europe, and 25 species are known from the United States, among them Diapheromera femorata, which sometimes defoliates oak forests Phasmids freely regenerate amputated legs and antennae; under certain conditions the stump of an antenna will regenerate a leg (SEE RECENERATION IN ANIMALS). (T, H, HL.)

STICKLEBACK, a group of small fishes (Gasterosteus) in the temperate some of the northern homisphere. The majority has been some the temperate some of the northern homisphere. The majority has been some that the some that the some that the same than the some than the

Sticklebacks are short-lived animals said to reach an age of three or four years. In spring each male selects a territory, which he farcely defends and to which he invites all females, until the nest is filled with owa. At this pernod he assumes a dress of blue and red. The eggs are comparatively large, one female depositing from 50 to 100.

The three-spined stickleback (G. couleatus) is found everywhere in northern and central Europe, northern Asia, and North America. The ten-spined stickleback (G. pangitins) is smaller than the three-spined species, rarely exceeding 2 in in length. Its geographical range nearly coincides with att of the other species, in, and is armed with 15 short spines. It is common round the British coasts. At suitable localities which are sheltered from the waves and overgrown with seawed, especially in rock pools and shallows covered with Zostera, one or two males establish themselves with their harens. The elaborate nest is constructed by binding together suitable fronds of seawed.

STIGAND (d 1072), archbishop of Canterbury, is first mentioned in 1020. He was then chaplain to Canute and afterward

to his son, Harold Harefoot, and after the death of Canute appears to have acted as the chief adviser of his widow, Emma In 1043 he was consecrated bishop of Elmhain and in 1047 was translated to Winchester, he supported Earl Godwine in his quarrel with Edward the Confessor, and in 1052 arranged the peace between the earl and the king In this year the archbishop of Canterbury, Robert of Jumièges, having been outlawed, Stigand was appointed to the archbishopric, but Pope Leo IX and his two successors refused to recognize him In 1058, however, Benedict X gave him the pall, but this pope was deposed in the following year Stigand is said by Norman writers to have crowned Haiold in Jan 1066, but this ceremony was probably performed by Aldred archbishop of York Stigand submitted to William, and assisted at his coronation. But the Conqueror was anxious to get rid of him. In 1070 he was deposed by the papal legates and was imprisoned at Winchester, where he died, probably on Feb 22, 1072 Stigand was an avaricious man and a great pluralist, holding the bishopric of Winchester after he became archbishop of Canterbury, in addition to several abbeys

See E A Freeman, The Norman Conquest (1870-76), vols. ii., iii. and iv., and J. R. Green, The Conquest of England (1899), vol. ii. STIGMA'TIZATION, the impression of stigmata. Origi-

nally, the process of marking or branding slaves and criminals. The aposalie Paul is the first to speak of singmata in a religious sense. He reminds the Galatians of the distinctive "marks (stagmata) of the Lord Jesus" in opposition to the old mark of cricumcision. "I bear the marks of the Lord Jesus in my body! (Gal. 5.17). Paul's stigmata were scars of wounds received during his apostolate from persons opposed to his preaching (II Cor 17:24 f).

Specifically, stigmatization is a phenomenon observed in a number of Christian saints and mystics for which no satisfactory natural explanation has been offered as yet. It consists of the appearance, on the body of a living person, of wounds or scars corresponding to those of the crucified Chrisi

The first and most celebrated stigmatization of this kind is that of St Prancis of Assis (178-1296). His biligraphers, Thomas of Celano, St. Bonaventure and other contemporares tell us that early one morning, Sept 14, 1244, while Prancis was praying on mount La Verna, a sax-winged seraph appeared to him bearing between his wings the form of one crucified and clearly the figure of Christ. When the apparition vanished, a great love of God was felt in Franci's soul and in his body there appeared an impression of the wounds of the Lord Jesus The reproduction of a lancewound, fresh and bleeding, was seen on his side, whence thereful after blood came out, on many occasions staining his garments. His hands and feet seemed perforated in the middle. Pope Alexander IV and many other witnesses declared that they had seen the stigmata both before and after his death.

According to Dr. A Imbert-Gourbeyre, up to 34r cases of stigmatization have been recorded after the time of St. Francis In 300 cases, the stigmatized person was a woman. Better known stigmatists of modern times are. Catherine Emmerch of Muenster, (1774-1824), Mary von Mfert of Kaltern, Tyrol, (1873-68); Louise Isteau of Bost de Haine, (1856-89). Two renowed cases of stigmatization belong to the 20th century, those of Gemma Galgani of Lucca, Italy, (1878-920) and of Theresa Neumann of Konnersreuth, Germany, German is the last stigmatist to be canonised by the Roman Catholic Church (May 2, 1940). However, she was declared a saint not on account of the stigmata to five for her berlov intrue. Gemma received the stigmata on June 8, 1899. In addition to the wounds in her hands, feet and side, she experienced also the stigmata to the ecrown of the story and the stigmata of the crown of the story and the st

The case of Theress Neumann attracted the attention of scholars and scientists for several years. Born on Good Friday, April 3, 1998, the received the first stigmats on the upper surface of her hands and feet on Good Friday, April 2, 1926. On this occasion, her eyes began to bleed profusely, a phenomenon that used to occur whenever she meditated on Christ's suffering. Stigmats on the lower surface of her hands and feet appeared on the follows.

lowing Good Friday, Apill 15, 1927, and in subsequent years speedy recovery of Vale college after the War of Independence those on her side, shoulder and brow became manifest. They his mellectual and theological breadth helped to secularize and were witnessed by thousands within the first decade of their appearance and became an object of study and investigation meteorological statistics; he imported silkworms and books or (Minichevier medicinische Wickienschrift, Nov. 18, 1927). It silk culture; he corresponded with many litterati; he undertool has been often observed that real stigmata cannot be cured, that the study of Hebrew at the age of 40 and became an ablt the wounds remain fresh and show no sign of suppuration even scholar, in short, his hunger for knowledge was insatiable Or Franklin's recommendation he was made a doctor of divinty.

Sabatter in his Fre de sont Franços d'Assure (1804), A Imbert-Gomberc, La dispositione (1804), G. Francisco (1904), J. Teodorowicz, Konnerresult in Lichte der Mythle und Psychologie, Bing tir by B. Kitsung (1904).

STILHENE, a glistening colourless crystalline hydrocarbon meltung at 1x3°C, and boiling at 3c6°C, and soluble in alcohol or ether It is prepared either by the action of sodium on benzylidene (benzal) chlouide, CaH, GCHCls, or by passing toluene over heated lead oxide Stübene is symmetrical diphenylethylene, CH<sub>2</sub>CH CHClg, and many of its derivatives are known to exist in two structural forms exhibiting stereoisomerism of the type shown by fumaric and malete cards. It is chiefly of interest as being the basis of several important synthetic dyes. Stiffener accomplexes, 44 Chaimineotilhene-2-drishiphonic acid, Stiffener accomplexes, 14 Chaimineotilhene-2-drishiphonic acid, and coupled with \$\theta-aphthylmine acid by successive treatment with aqueous causite sodia and alkaline inc dust, when diazotises with aqueous causite sodia and alkaline inc dust, when diazotise with account of the stability of the solid property of the stability of the stabi

Shibene colours—Varous cotton yellows and oranges are obtained by boiling p-nitrotoluen-s-sulphonic acid with aqueous caustic soda alone (Chlorazol yellow), in the presence of oxidisable substances such as glycerol, sodium sulphite, or gallic acid (Chlorazol Fast Orange) or with oxidising agents such as sodium hypochlorute (Chlorazol Fast Yellow)

Diphenylacetylene or tolane, C6H5-C CC6H5, colourless crys-

tals melting at 60° C, results from the action of alcoholic potash on stilbene dibromide (G T.M)

STILBITE, a mineral of the zeolite group consisting of hydrated calcium aluminium silicate, CaAl<sub>2</sub>(SiO<sub>2</sub>)<sub>6</sub>+6H<sub>2</sub>O Usually a small proportion of the calcium is replaced by sodium. Crystals are monoclinic, and are invariably twinned, giving rise to complex groups and characteristic sheaf-like aggregates. The colour is usually white, sometimes red, and on the perfect cleavage (parallel to the plane of symmetry) the lustre is markedly pearly; hence the name stilbite (Gr  $\sigma \tau t \lambda \beta \epsilon \nu$ , to shine) given by R. J. Hauy in 1796. After the separation of heulandite from this species in 1818, the name desmine (δέσμη, a bundle) was proposed, and this name is now employed in Germany. The hardness is 3.5 and the specific gravity 2-2. Stilbite occurs with other zeolites in the amygdaloidal cavities of basic volcanic rocks; it is sometimes found in granite and gneiss, and exceptionally in metalliferous veins Beautiful, salmon-pink crystals occur with pale green apophyllite in the Deccan traps near Bombay and Poona; white sheaf-like groups encrust the calcite (Iceland-spar) of Berufford near Djupivogr, Iceland; and crystals of a brick-red colour are found at Old Kilpatrick, Dumbartonshire.

STILES, EZRA (1727—1799). American clergymen and educationalist, seventh president of Vale college, was born on Nov. 20, 729; in North Haven, a parish of New Haven (Connecticut). He graduarde at Vale in 749—55. He also preached in 7790 and was a tutor at Yale in 1749—55. He also preached in 7790 to the Indians at Stockbridge, was admitted to the bar in 778, and practised in New Haven for two years. After pastorates at Newport (R.I.) and Portsmouth (N.H.) he became in 778 president of Yale college and professor of ecclesiastical history processing the result of the results of the New Haven of the New Haven of the Yale college and professor of edivality and lecturing on minny subjects. He died in New Haven on May 12, 1793. His wise administration as president and coossible values.

his intellectual and theological breadth helped to secularize and strengthen the college. He carefully kept thermometric and meteorological statistics; he imported silkworms and books on silk culture; he corresponded with many litterati; he undertook the study of Hebrew at the age of 40 and became an able scholar, in short, his hunger for knowledge was insatiable On Franklin's recommendation he was made a doctor of divinity by the University of Edinburgh in 1765, and he was awarded other honorary degrees in his own country. Dr Stiles published a number of sermons, an Account of the Settlement of Bristol, Rhode Island (1785); and a History of Three of the Judges of King Charles I. (1794). His Literary Diary (3 vol., 1901) was edited by F B. Dexter, who quotes largely from Dr Stiles's Itmeraries Extracts from the Itineraries and Other Miscellames with selections from Dr. Stiles's correspondence prepared by the same editor appeared in 1916. Both give a valuable picture of New England life and contemporary figures.

STILICHO, FLAVIUS (?-408), Roman general and statesman, was the son of a Vandal who had served as an officer in the army of the emperor Valens (364-378). He himself entered the imperial army at an early age and speedily attained high promotion He had already become master of the horse when in 383 he was sent by Theodosius (379-395) at the head of an embassy to the Persian king. Sanor III His mission was very successful. and soon after his return he was made count of the domestics and received in marriage Serena, the emperor's niece and adopted daughter In 385 he was appointed master of the soldiery m Thrace, and shortly afterwards directed energetic campaigns in Britain against Picts, Scots and Saxons, and along the Rhine against other barbarians Stilicho and Serena were named guardians of the youthful Honorius when the latter was created joint emperor in 394 Rivalry had already existed between Stilicho and Rufinus, the practorian practect of the East. Consequently in 395, after a successful campaign against the Germans on the Rhine, Stilicho marched east, with the design of displacing Rufinus; and by connivance with the barbarians he procured the assassination of Rufinus at the close of the year, and thereby became virtual master of the empire In 306 he fought in Greece against the Visigoths, but an arrangement was effected whereby their chieftain Alaric was appointed master of the soldiery in Illyricum (397). In 398 he quelled Gildo's revolt in Africa and married his daughter Maria to Honorius. Two years later he was consul. He thwarted the efforts of Alaric and Radagaisus to seize lands in Italy by his victories on the Danube at Pollentia and Verona in 401-3.

vertical in 401-3.

In a second campaign against Radagaisus, who led a large force of various Germanic peoples into Italy in 495, he surrounded the barbarian chieftain on the rocks of Fissole and starved him into surrender. Early in 408 he married his second daughter Thermanità to Honorius. It was rumoured about this time that Silikho was plotting with Alaric and with Germans in Gaul and the contract of the con

by false promises to quit the church in which he had taken sanctury, was executed on Aug. 23, 408.

The principal sources for the life of Stilkho are the histories of Caudian See T. Hodgkin, Italy and her Inveders, vols. i, and it. (Oriodt, 280.); E. Gibbon, Deckee and Falt of the Romes Empire, edited by J. B. Burry, vol. ii. (1902). P. Villatt, the Borberton Avasibus of Italy Society in the last cauting of the Witter Empire (1809). Mommsen in Hernes xviiii; and K. Birtin, Späirömische Charakterbilder (Leipzig, 1919).

STILL, ANDREW T. (1828-1917), founder of esteopathy, was born in Jonesville, Va., on Aug. 6, 1828. His family moved in 1837 to Macon county, Missouri, and later to the Shawnee

reservation near Kansas City, Kansas Still took an active part and draperies, Venetian and Bohemian glass richly ornamented in the slave question in Kansas, and in 1857 was elected to the Kansas Territorial legislature on the Free State ticket. He began searching for other means than medicine to combat disease and formulated his principles of osteopathy in 1874. He underwent a long period of opposition, but finally, in 1892, founded the American School of Osteopathy at Kirksville, Mo, in conjunction with William Smith, a Scottish physician In 1922 the Andrew T Still College of Osteopathy and Surgery was founded and merged with the original American school. He was the author of The Philosophy of Osteopathy (1899), Autobiography of Andrew T. Still (1897) and Osteopathy, Research and Practice (1910). See "Andrew T Still," Missouri Historical Review, vol. xix, 1924.

STILL, JOHN (15437-1608), bishop of Bath and Wells, was born at Grantham, Lines He studied at Christ's college, Cambridge He was appointed in 1570 Lady Margaret professor of divinity, subsequently held livings in Suffolk and Yorkshire, and was master successively of St. John's College (1574) and of Trinity College (1577). Still was vice-chancellor of his university in 1575-76 and again in 1592-93, and was 1afsed to the bishopric of Bath and Wells in 1593 He died on Feb. 26, 1608, leaving a large fortune from lead mines discovered in the Mendin Hills. He was for some time generally believed to be the author of the English comedy Gammer Gurton's Needle, which is now ascribed to William Stevenson (q v.)

STILL ENGINE: See INTERNAL COMBUSTION ENGINES

STILLINGFLEET, EDWARD (1635-1699), English divine, was born at Cranborne, Dorset, on April 17, 1635 He graduated from St. John's college, Cambridge, in 1652, and in the following year was elected to a fellowship. At Sutton, Beds, of which he was vicar, he published (1659) his Irenicum in which he sought to give expression to the prevailing weariness of the faction between Episcopacy and Presbyterianism, and to find some compromise He looks upon the form of church government as non-essential, but condemns Nonconformity. Although in 1680 he published his Unreasonableness of Separation, his willingness to serve on the ecclesiastical commission of 1689, and the interpretation he then proposed of the damnatory clauses of the Athanasian creed, are proof that to the end he leaned towards toleration His rapid promotion dates from 1662, when he published Origines sacrae, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures and the Matters therein contained. In 1665 the earl of Southampton presented him to St. Andrew's, Holborn, two years later he became prebendary of St Paul's, in 1668 chaplain to Charles II., in 1670 canon residentiary, and in 1678 dean of St Paul's He was also preacher at the Rolls Chapel and reader at the Temple. Finally he was consecrated bishop of Worcester on Oct 13, 1689. During these years he was ceaselessly engaged in controversy with Nonconformists, Romanists, Deists and Socinians. His various learning, his dialectical expertness, and his massive judgment, rendered him a formidable antagonist; but the respect entertained for him by his opponents was chiefly aroused by his recognized love of truth. The range of his learning is most clearly seen in his Bishop's Right to Vote in Parliament in Cases Capital. His Origines Britannicae, or Antiquities of the British Church (1685), is a strange mixture of critical and uncritical research. In his closing years he had some controversy with John Locke, whom he considered to have impugned the doctrine of the Trinity. He died at Westminster on March 28, 1699. His manuscripts were bought by Robert Harley, afterwards Earl of Oxford.

A collected edition of his works, with life by Richard Bentley, was published in London, 6 vols. (1710); and a useful edition of The Doctrines and Practices of the Church of Rome Truly Represented was published in 1845 by William Cunningham.

STILL-LIFE PAINTING, the art of painting inanimate objects for their beauty of colour, line or arrangement. It was first developed as an individual branch of easel painting by the artists of the Netherland school of painters. Families of artists chose this simple line of art for their life's work. Gold and siland even jewels, scientifically arranged for scintillating effects. were motifs for some of the most brilliant artists. Simple kitchen utensils of brass and copper, with meat, fish and vegetables. made fine subjects for colour and line. The sparkle of metals, the glitter of wet fish, the deep and rich tones of meat and vegetables-what better material could the painter desire!

Exquisite drawing, with painstaking draughtsmanship as a primary factor, resulted in paintings that were sought not only by the rich burghers, but by visiting princes and ambassadors In every museum may be found these masterpieces, and although not so numerous as the many rows of portraits, genre and religious canvases, they, nevertheless, hold their high place in Dutch art

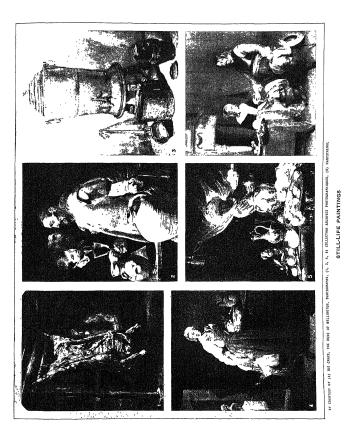

The Flemish and Dutch artists felt, and so did many true lovers of the fine arts of that time, that the subject of a picture was not the only motif worth while; that an arrangement beautifully composed, either for luxurious abundance or for simplicity in colour, tone, values and line, would make a noble work of art, in spite of what higher thought might find in portraying character in the portrait and deep feeling in the religious picture They argued that a well painted still-life was a greater art production than a badly painted Madonna, however well conceived

Subject-matter .- Pictures of the life of the people themselves, their houses, gardens, the interior of the splendidly furmished homes of merchants and aristocrats, rich in hangings and elaborate in table service, made beautiful settings for the painter The everyday life of the people around the artist showed him just what he wanted. Besides, it furnished a subject that was simpler to do than the literary picture, as well as being more straightforward and true People in silk and velvet, visiting in well-appointed rooms to listen to music or to partake of wine and cake or fruit. served on silver or choice porcelain, were none the better as subjects than a girl scouring a brass kettle in the kitchen.

That greatest part of the painter's knowledge, the observation of values, which means rendering the lights and shadows of a subject regardless of local colour, was first thoroughly understood by these artists, and is the basis of all sound painting From the work of these men, still-life developed. The principle is the same, the interiors being to a great extent still-life. There is usually very little expression or movement needed for the figures. However well painted the heads, the clothes, even the glass of amber-coloured wine in the lady's hand, seem almost of the same interest as the head. Take the figures out and the pure still-life is the result. The simple composition of a few peaches on a piece of delft with a silver pitcher and an ornamented glass half full of wine is all that a master like Willem Kalf needs to make a supreme painting

Technique.—Often in the galleries and at exhibitions, critical visitors, some of whom are professional painters, ask. "What is still-life?" Reproducing the roundness and firmness of a red apple is not very different from the modelling of a head. Lovers of painting look for something different in a canvas, something that for them means beauty or truth-and not every one sees the same beauty in a picture painted by a master. Take Velázquez' "Aguador" for an example; to the painter, a quiet study of model-ling, with remarkable still-life; to one with perhaps no ability as a painter, a thoughtful study of a man's head, to another a beautiful head of a boy. Velázquez had a number of interesting still-life pictures. In "The Steward" and "Old Woman Frying Eggs," each has a single figure in the composition, but the pictures are evidently made for close studies of inanimate life, dead fish, meat, jars and glass, masses of objects, scattered all over the canvas Rembrandt's "Flayed Ox" in the Louvre is a great example of noble quality, rich in colour, bold in treatment, closely observed in values, and of great simplicity-a masterpiece.

Pieter Aertsen, early 16th century, one of the first absolute still-life painters, although at times introducing figures in the background of some of his pictures, painted pictures of meats, vegetables, etc., in the kitchen or larder His large canvas in Uppsala, representing a butcher-shop with a calf's head, a side of beef, a pig's head and sausages, fowl, fish and all sorts of gruesome details of what one expects to find in such a place, is typical. ver cups, flagons and plates of porcelain and delft, oriental rugs. The canvas is overfilled, every small place is crowded, and

4. "Fish" by Henri Matisse (1869-

although correct in drawing, well coloured and a picture most interesting, it is in questionable taste.

Abraham van Beyenn (1630-75) stands eut as one of the forment painters of rish, producing well composed paintings, gloming with bright colours and glistening surfaces. The painting of wei, sparking fish gives opportunities to the student for the study of brilliant light against the deep and rich notes in the wet rish, and as the fish very soon deteriorates in colour and form, the canvas must be painted quickly, in the heat of enthusiasm, thus bringing forth the finest results, the most spontaneous work.

Joachim Buckelaer painted fish, as did Alexander Adriassen and, in their late years, Vollon, Manet and Chase

Jan Davidsz van Heem and his son, Cornelius de Heem, the two most celebrated members of a large family of still-life painters, are separately noticed. Jan was one of the earliest and ablest. The realism of the individual flower or peach was more desired by these painters than the ensemble of the picture. Jan an Huysum (q, v) reached the top as a flower painter whose

style was similar to that of the de Heems.

Willem Kalf, like Willem Classz Heda, had finer perception of tone and envelopment. Both were painters of rich objects that were executed in the adopted style of the Dutch, but with keen observation of values and tonality; they were taught by masters like Vermeer and Terborch.

Frans Shyders' large game compositions are highly decorative, his fruit rich in colour, well drawn and painted, but overfilled with details and without concentration of the modif. No air in them! The pictures of game that his pupil, Jan Fyt, painted are well studied, realistic in the weight of deer and hare, and in the quality of the painting of fur and feathers. Jan Weenix was a highly decorative panter of dead game in luxinous surroundings, garden backgrounds with decorated vases, the implements for the bunt and its soon.

In all this interesting still-life work it was always the manner that was considered superior to the matter, and it was always the school that called for excellence of craftsmanship. Every master had his pupils who followed his style; father taught son, and the son taught his son; it was a trade that had to be learned

Without absolute knowledge of his tools and the preparation of the canvas or panel, one did not count for much in the craft. So-called "visions" were not considered in the Netherlands, as they were in Italy. Pictures that could be studied and loved at short range were called for, and the work could not be carelessly done. Therefore, something was often missing, even in this beautiful work. It left no room for imagnation. It was only for the eye—charming to look at, but nothing to dream about—and was generally the work of the panier and tarely of the artist,

Chardin -- Tean Baptiste Simeon Chardin lifted still-life to a higher plane in art than the Hollanders and Flemings of former years. Understanding their methods, he added to their technique air and light as the aim to search for. His simplicity saw beauty in his daily surroundings; his honesty rendered them with absolute truth. Every utensil in his kitchen we know-the copper waterfountain, the charcoal brazier, the brass kettles, the handsome water-jar, the bread knife, as well as the large loaf of bread, the herrings, cuts of meat, onions and pieces of china. Chardin's living-room we know, with the straight-backed chairs and the bird in its cage on a stand. We know the housewife with her white apron -and how splendid a white! Chardin's whites are miracles of painting. The white jug and the white fowl in the still-life in the Boston museum are unequalled. Few painters of all time have been able to handle white pigment as Chardin could. James McNeill Whistler was among the few.

Among files earliest pictures was to "Skate." now in the Louver. This was accepted by the academy as his diploma picture, simply painted and freer in treatment than other canvases of his early career. He painted a great many interiors, with one or two figures. Again and again't is the light that predominates, the atmosphere of the from o'r rooms, for we often look through an open door-into another room, and that from full of light. Every figure has its weight, stands soundly on its feet and is well in its distance from the onlower and from the wall behind.

As still-life painting or interior with figure, it has every quality aboven; every colour value is observed; the drawing is easy, never overdrawn, and still never slighted. Chardin's textures are removed as the still and citch is cloth, every edge, the despair of the average painter, if min but well beineded, light and air are over and around every figure or object. This is still-life painting, an answer to "What is still-life?"

Later Still-life Artists—Chardin died in 1779, and for meatly a century there were no still-hie panters of note; there was practically no interest in notione more. When Courbet started his bold and vigorous manner of panting, he was alone, he pantied what he saw and in a manner of bis own invention. Whatever in nature looked worth panting he paintied—figures, landscape, marines and still-life. His still-life canvases are done truthfully and spontaneously, and are of a flat, well-coloured technique. Several of his pictures have a stag in them, similar in motion to those of Snyders or Wentis. But with more weight, and greater organality.

Manet was an artist who painted for excellence, and his stilllife work, of which he did a great deal, is always of a high order Simple and full of high, the canvas is never overfilled. Manet was also an individual who saw with his own eyes and painted in a flat manner. Jocal colour and values being purposely shighted.

Antoine Vollon painted landscapes, but is better known for his still-life, in which he was very prolific. Most of his work was done in one sitting, and in a decorative, well-arranged, somewhat Dutch manner.

Vollon's picture of "Fish" in the Luxembourg is a splendid piece of painting, with its dark shadows, almost monotone, and the wet and slimy fish in brilliant light. His reputation was widespread.

Bonvin and Fantin-Latour were men of well-mented reputation Fantin-Latour's flower paintings are tastefully arranged and finely executed Bonvin's work, simple and truthful, is based on Chardin's methods.

Of the American painters, William M. Chase (1849—1916) painted fish, pots and brass kettles, and pictures of great brilliancy Julian Alden Weir's flowers are noted for their equisite delicacy and beauty. (See also Painting; Flower Painting) (É CN.)

STILLMAN, WILLIAM JAMES (1828-1901), American painter and journalist, was born at Schenectady (N. Y), June 1, 1828. He graduated at Union college, Schenectady, in 1848. He studied art under Frederick E. Church and carly in 1850 went to England, where he fell so much under the influence of Rossetti and Millais that on his return home in the same year he speedily became known as the "American Pre-Raphaelite." He studied art under Yvon in Paris, returned to the United States and devoted himself to landscape painting on Upper Saranac Lake in the Adirondacks and in New York City, where he started the Crayon. When it failed for want of funds, Stillman removed to Cambridge, Massachusetts. He returned to England, and afterwards painted with Ruskin in Switzerland. He was in Normandy in 1861 when the American Civil War broke out. His health was too weak for him to serve in the Northern ranks and he was appointed United States consul in Rome. In 1865 he resigned, but immediately afterwards he was appointed to Crete. He was an editor of Scribner's Magazine for a short time When in London lived with D. G. Rossetti. When the insurrection of 1875 broke out in Hercegovina he went there as a correspondent of The Times, and his letters from the Balkans aroused so much interest that the British government was induced to lend its countenance to Montenegrin aspirations. In 1877-83 he served as the correspondent of The Times at Athens; in 1886-98 at Rome. After his retirement he lived in Surrey, where he died on July 6, 1901. He wrote The Cretan Insurrection 1866-1868 (1874), On the Track of Ulysses (1888), Billy and Hans (1897) and Francesco Crispi (1800).

See his Autobiography of a Journalist (Boston, 1901)

STILLWATER, a city of eastern Minnesota, USA, on the St Croix river, at the head of Lake St Croix, 20 mi. NE of St. Paul; the county seat of Washington county It is served by the Chicago, Milwaukee, St Paul and Pacific, the Chicago, St Paul, Minneapolis and Omaha, and the Northern Pacific railways Pop. (1950) 7,643, and it was 7,013 in 1940 The city has a picturesque situation on bluffs high above the river It is the seat of the state prison (established 1851), a shipping point for the agricultural products of the region, and a manufacturing centre of growing importance Before the exhaustion of the forests, it had a large trade in pine lumber Stillwater was settled in 1843, laid out in 1848, and chartered in 1854. The "Stillwater Convention" of 1848 was the first step toward the erection of Minnesota Territory

STILO PRAECONINUS, LUCIUS AELIUS (c. 154-74 B C ), of Lanuvium, the earliest Roman philologist, belonged to the equestrian order. His aristocratic sympathies were so strong that he voluntarily accompanied O Caecilius Metellus Numidicus into exile. At Rome he divided his time between teaching and literary work. His most famous pupils were Varro and Cicero, and amongst his friends were Coelius Antipater, the historian, and Lucilius, the satirist, who dedicated their works to him Only a few fragments of his works remain. He wrote commentaries on the hymns of the Salu, and (probably) on the Twelve Tables, and investigated the genumeness of the Plautine comedies, of which he recognized 25, four more than were allowed by Varro The rhetorical treatise Ad Herennium has been attributed to him by some modern scholars.

1900), p 148.

STILT (Himantopus himantopus), a bird of the plover famly (see PLOVER), remarkable for the extreme length of its slender legs. The bill is long and straight; the legs red, the wings and back black; the head, neck and

lower parts white

Its food consists of small arthropods, which it obtains by wading in shallow water. It ranges over Europe and Asia, not breeding northward of the Danube valley. The nest is a slight structure on the margin of a pool or lake, and contains four eggs, which resemble those of the ovster-catcher (q.v.) In America, from Oregon southward to Brazil, occurs the black-necked stilt, THE STILT (HIMANTOPUS HIMAN-H. mgricollis, Other species oc-

cur in South America, Australia and New Zealand. The stilts are

allied to the avocets (q.v.), and, like them, spend much time wading in shallow water.

STILTS, poles with footrests fixed at a certain distance above the ground. They were originally designed for use in crossing rivers and marshes. As a means of amusement stilts have been used by all peoples in all ages, as well as by the inhabitants of marshy or flooded districts. The city of Namur in Belgium, which formerly suffered from the overflowing of the rivers Sambre and Meuse, has been celebrated for its stilt-walkers for many centuries. Not only the townspeople but also the soldiers used stilts. The governor of Namur having promised the archduke Albert (about 1600) a company of soldiers that should neither ride nor walk. sent a detachment on stilts, which so pleased the archduke that he conferred upon the city perpetual exemption from the beertax, no small privilege at that time.

The home of stilt-walking at the present day is the department of Landes in Gascony, where, owing to the impermeability of the subsoil, all low-lying districts are converted into marshes. Stilts

used by children are very long, the upper half being held under

the arms, they are not strapped to the leg
STIMSON, HENRY LEWIS (1867-1950), US lawyer and statesman, was born in New York city on Sept 21, 1867, and educated at Yale (AB, 1888) and Harvard (AM, 1889) universities He attended the Harvard Law school and in 1801 was admitted to the New York bar. In 1906 he was appointed U.S. attorney for the southern district of New York state This position he relinquished in 1910 to become the unsuccessful candidate of the Republican party for governor of New York In 1911 he was appointed secretary of war by Pres Wilham Taft, in which office he continued from May 1011 to March 1913 During US participation in World War I he served in France as colonel of the 31st field artillery In 1927 he was sent by Pres Calvin Coolidge as a special commissioner to Nicaragua, where he met Pres. Adolfo Díaz and the rebel leader José Moncada and was instrumental in persuading both leaders to lay down their arms on condition that the U.S would supervise the 1928 election His success on this mission, together with his study of the Philippine question in 1926, led to his appointment, in Dec. 1927, as governor general of the Philippine Islands. He succeeded Maj Gen Leonard Wood, whose policies he continued with notable success. As secretary of state in Herbert Hoover's cabinet from 1929 to 1933, he urged international opposition to Japan's aggressions in Manchuria, He led the U S delegations to the London naval conference in 1930 and the disarmament conference of 1932. He served again as secretary of war from 1940 to 1945. He died Oct 20, 1950, in Huntington, N.Y.

STINKHORN, the popular name of a group of fungi belonging to the Basidiomycetes, so called because of their carnonlike odour. The young plant (egg) resembles a small puff-ball (q.v) but soon splits open at the apex when a stalk emerges with a conical, slimy, evil-smelling head on which the spores are borne. The spores are dispersed by insects attracted by

the odour.

STINK-WOOD, a South African tree, known botanically as Ocotea bullata, and a member of the family Lauraceae. Other names for it are Cape walnut, stinkhout, Cape laurel and laurel wood It derives its name from having a strong and unpleasant smell when freshly felled. It is used for building in South Africa and is said to be a substitute for teak and equally durable The wood is dark walnut or reddish brown to black with a yellow sapwood, and the grain extremely fine, close, dense and smooth

STINNES, HUGO (1870-1924), German industrialist, was born in Mulheim on Feb. 12, 1870. Educated as a mining engineer, he entered his grandfather's firm in 1890, but two years later established a business of his own, with a capital of 50,000 marks. The business expanded steadily and came to include, besides dealing in coal, the ownership of coal mines, barges, river steamers and sea-going vessels. Stinnes organized an international business in coal, including the importation of coal from England He built up a fleet of steamers trading in the North Sea, the Baltic, the Mediterranean and the Black Sea. He also established iron and steel factories. During World War I he commanded a large share of the industrial work required by the German authorities, and rapidly increased his shipping interests. In 1920 he entered the Reichstag as a member of the German People's Party (the former National Liberal party). He began to buy up newspapers, whose democratic opinions were quickly modified in accordance with his own. In 1921 he was reported to be contem-plating the formation of a super-trust to control the whole of German industry. He died in Berlin April 10, 1924. After his death the business, conducted by his son, rapidly shrank In June 1925 a conference of bankers was called to investigate the financial affairs of the trust; and but by bit the great organization was liquidated and sold. In Oct. 1925 a new company was registered at Hamburg under the title of Hugo Stinnes Coal Trade and Shipping Co., Ltd., the Stinnes family retaining 40% of the shares.

STIPPLE AND CRAYON ENGRAVING. Stippleengraving was a little art of prettiness and daintiness, particularly well adapted to the translation of anecdotic pictures of a sentimental, mildly romantic, or domestic character, such as were

BY COURTEST OF (1, 2, 3) FRANK Y SABIN, (4) THE TRUSTEES OF THE BRITISH MUSEUM

# ENGLISH STIPPLE ENGRAVINGS OF THE 18TH CENTURY

Stipple engraving consists of a design drawn in a series or group of dots through an etching ground on a copper plate, and bitten with acid, then completed with dots made directly in the copper by a curved stipple-graver and perhaps a toothed wheel called a roulette

1. "Countes Senicer," engraved by Francisco Bartelarii (1727-1813)
by William Word (1764-1826) star the culnting by George Morland the Mascurate," engraved by John Rachael Smith (1782-1812) after the painting by George Morland (1781-1804). "George Morland (1781-1804)." George Roman (1714-1808)

tuned out in great numbers to supply a vogue in the English sallers' windows, and few native engravers could resist the easy maket during the reggs of George HII, many of which, popular attraction of the new method, while it brought also Italian and in the day, survive only in the colour-prints and, though rarely of much attistic value, are yet now highly valued for their ment in survival. Nevertheless there were in the brief hey-day of the art a few among the multitude of designers and engraves who, realising its limitations, made the most of its qualities, and these, such as J. R. Smith, William Ward and John Jones, the special respectations with the survival of the special possibility of the survival of th

As a separate method, stipple-engraving came to England from France probably about 1764, by way of the crayon manner and the pastel, and these had evolved originally from the dotted manner, to which Ludwing von Siegen refers; in amounting the wonders of his own invention of mezzotint in 1642, as one of the modes of enganing which it was not The dotted manner, a process of punching the plate with awd and mailet, called opps multel, was used for its own sake with pictorial effect by Jan Lutma, an Amsterdam goldsmith, and the son of Rembrandt's sitter; but graven dots had been used earlier as accessory to line-engraving by Guiho Campagnola, Ottavio Leon, and others, while in England the eathlest important engraver of portraits, Whiliam Rogers, in Queen Elambeth's rege, had supplied the face of the Queen, while of Chriefs. If

But in the 18th century, when the crayon and pastel drawings of Boucher and others were popular in France, the aim of the engravers was to reproduce their texture on the copper-plate. The idea was in the air, so to speak, and several were engaged in the attempt to materialize it Thus the invention of the crayon manner was claimed separately by Jean Charles François, Gilles Demarteau, who used his own version of it with artistic feeling. and Louis Marin Bonnet, an ingenious engraver to whom we owe at least the "pastel manner" This was a subtle development of the crayon mode admitting colour variety from a series of plates. as we may see in Bonnet's really fine print, La Tête de Flore, after Boucher, but François seems to have been actually the first in the field The means used to imutate crayon drawing resembled soft-ground etching, though to produce the appearance of the chalk lines the etching-ground was perforated by tools of the roulette order, and various kinds of needles, while, after the usual biting by the acid, the finishing touches were given by graver, dry-point and roulette, though one often fancies the methods of soft-ground had been employed. François taught this crayon engraving, and with it the application of colour in printing à la poupée, to William Wynn Ryland, a young English line-engraver, who had been studying with Le Bas in Paris, and who, when funds were lacking after his return to London, bethought him of the new manner of engraving he had learnt. Then having called Bartolozzi into collaboration, they both medified and developed it as stipple-engraving.

The new method proved very easy of accomplishment, simple and rapid. The outline was etched in a series of dots, and all the shadows were put in with large or closer dots, or tiny groups of dots When all the biting was over, the ground was removed, and the finishing was done with dry-point and stipple-graver, a curved tool. Then the printing was done with black, red, or several coloured inks, a rag-stump, or poupée, being used, and the plate freshly cleaned for each impression. Beginning by translating the pretty pseudo-classical designs of Angelica Kauffman and Cipriani, which acquired a very popular vogue, Ryland and Bartolozzi found the new method exceedingly profitable. To the ready hand of Bartolozzi it came almost as a fairy gift, with the facilities of the medium linking themselves to his sweet caressing sense of beauty. Indeed, he developed it with richer character in its fine shades than the unfortunate Ryland could do, as we may see in many notable prints after Reynolds and other distinguished painters, All the painters of the day were anxious to share in the profits so readily made by the stipple-prints which were filling the print-

attraction of the new method, while it brought also Italian and French engravers to learn it, and work here for the English market. There was also, up to the war with revolutionary France in 1793, a great trade in English prints on the continent, and Bonnet and other French engravers, adopting the stipple method, tried to get a share in this trade by issuing prints with titles often in misspelt English Sir Robert Strange, the eminent line-engraves, launched an indignant tirade against stipple, and even denied its claim to be regarded as engraving at all, though there was no denying its efficacy as a medium for colour-printing, the white of the paper, showing between the tinted dots, affording a peculiarly luminous quality, and thus giving it a superiority over the coloured mezzotint, though it must be admitted that rarely was the stipple or the mezzotint of old time completely printed in colours, some portions invariably being left to be coloured by hand. Nevertheless, the popularity of stipple continued as long as the special subjects for which it was used remained in fashion, and as long as the leading 18th century painters and engravers survived the period of their comparatively short though successful collaboration, but it really wanted with the advent of colour-lithography. Stipple-engraving is rarely practised nowadays as a separate art, though a recent attempt has been made to revive it for original expression by Dorothy Woollard As a medium for original colourprinting it has completely given place to aquatint, woodcut or panting it ass Competerly given piete to adjustin, wooded to wood engaving lithography or relief-etching from several plates where the plates of the plates of the plates of the plates (Spend Western Colors) and the plates of the plates of the (1906). STIRES, ERNEST MILMORE (1868—1951), bishop of Long Island, was bom in Norfolk, Va, on May 22, 1866 Herrecoved the degree of B. Litt at the University of Virginia in 1885, and from 1889-91 continued his studies at the Episcopal Heological seminary of Virginia, receiving the degree of D.D. at Trunty college in 1901 The degree of L.D. was conferred upon him at Kenyon college in 1903. He received his first appointment as rector at West Point in 1891, and in 1893 went to the Church of the Good Shepherd in Augusta, Ga. In the same year he was called to Grace church, Chicago, where he remained until 1901. He then accepted a call to 8t. Thomas's church, New York He was consecrated bishop of Long Island on Nov 24, 1925, and he served in that capacity until his retriement in 1941.

He died in Palm Beach, Fla, on Feb. 12, 1951 STIRLING, WILLIAM ALEXANDER, EARL OF (c 1567-1640), Scottish poet and statesman, generally known as William Alexander, was born at Menstrie House, near Stirling, about 1567, and probably educated at Stirling Grammar school. He may also have been to the universities of Glasgow and Leyden. He followed James VI. to England, where he became one of the gentlemen-extraordinary of Prince Henry's chamber. For the prince he wrote his Paraenesis to the Prince . . . (1604), a poem in eight-lined stanzas on the theme of princely duty He was knighted in 1609, in 1614 he was appointed master of requests, and in July 1615 to a seat in the Scottish privy council. In 1613 he began a correspondence with Drummond of Hawthornden In 1621 he received from James I, enormous grants of land in America, including Nova Scotia and New Brunswick, and was appointed lieutenant-governor of the new colony which, however, was ceded to the French in 1632. (See Nova Scotia: History.) From 1626 till his death he was the king's secretary for Scotland, and in 1630 was created viscount Stirling and Lord Alexander of Tullibody. In 1631 he edited and published a translation of the Psalms said to be by James I. In 1639 he became earl of Donovan. He died on Feb. 12, 1640, in London

Alexander's poetical miscellanies and minor verse include Aurora, containing the first fancies of the author's youth (1604); An Elejis on the Death of Prince Henrie, and shorter pieces He also wrote four tragedles, Darius (1603); Croesus (1604); The Alexandreau (1605), and Julius Caesus (1607); the first two of which were published together in 1604 as the Monarchicks Tragedles; they are didactic poems of dialoques rather than plant but they contain some fine solloques Of Alexander's heroic poem north side of the square is the chapel royal, founded by Alex-Donathon only the first book was written Donatedly, or The Order and the T, rebuilt in the 15th century and again 15th by 15th b

STIRLING, WILLIAM ALEXANDER, titular EARL OF (1726-1783), American soldier, was born in New York city. He served first as commissary and then as aide-de-camp to Governor William Shirley at the beginning of the French and Indian War, and in 1756 he accompanied Shirley to England, where he prosecuted his claim to the earldom of Stirling In 1759 an Edinburgh jury declared him to be the nearest heir to the last earl of Stirling, and in 1761 he returned to America and assumed the title of Lord Stirling by which he was afterwards known in America, He became a member of the New Jersey provincial council and surveyor general of the colony. In 1775 he sided with the patriot cause and was appointed colonel of a regiment in New Jersey. In March he became brigadier-general, and for a time was in command at New York, and supervised the fortification of the city and harbour. At the battle of Long Island he was taken prisoner, but was soon afterwards exchanged, and in Feb 1777 became a major-general. He participated in the battles of Trenton, Princeton, Brandywine and Germantown, and especially distinguished himself at Monmouth He took an active part in exposing the Conway Cabal, presided over the court-martial of General Charles Lee, and enjoyed the confidence of Washington to an unusual degree. In Oct. 1781 he took command of the northern department at Albany to check an expected invasion from Canada He died at Albany on Jan 15, 1783. He was a member of the board of governors of King's college (now Columbia university) and was devoted to the study of mathematics and astronomy.

See W. A Duer, "Life of William Alexander, Earl of Stirling," in Vol ii of the Collections of the New Jersey Hist. Soc. (1847).

STRLING, royal, large and parliamentary burgh, river port and county town of Stirlingshire, Scotland. Pop. (1938), 23,552. It is finely situated on the right bank of the Forth, 394 mi. N.W. of Edinburgh and 29½ mi. N.E. of Glasgow, being served by the L.N.E. and L.M.S. railways. The old town occupies the slopes of a basaltic hill (420 ft. above the sea) terminating on the north and west in a precipice. The modern quarters have been laid out on the level ground at the base, especially toward the south. Remains of a town wall exist at the south end of the Black walk, Formerly there were two main entrances-the South port and the "auld brig" over the Forth to the north, a high-pitched structure of four arches, now used only by foot-passengers. It dates from the end of the 14th century and was once literally "the key to the Highlands." Just below it is the bridge erected in 1829 from designs by Robert Stevenson, and below this again the railway viaduct. The castle crowning the hill is of unknown age, but from the time that Alexander I died within its walls in 1124 until the union of the crowns in 1603, it was intimately associated with the fortunes of the Scottish monarchs. It is approached from the esplanade, on which stands a colossal statue of Robert Bruce The main gateway, built by James III, gives access to the lower and then to the upper square, on the south side of which stands the palace, begun by James V (1540) and completed by Mary of Guise. The east side of the quadrangle is occupied by the parliament house, a Gothic building of the time

ander I, rebuilt in the 15th century and again in 1594 by James VI (who was christened in it), and afterwards converted into an armoury and finally a storeroom. In the plain to the southwest were the King's gardens, now under grass, with an octagonal turf-covered mound called the King's Knot in the centre Farther south lies the King's park. On a hill of lower elevation than the castle and separated from the esplanade by a depression styled the Valley-the tilting-ground of former times-a cemetery has been laid out Here is the Virgin Martyrs' memorial, in memory of Margaret Maclachlan and Margaret Wilson, who were drowned by the rising tide in Wigtown bay for their fidelity to the Covenant (1685); the large pyramid to the memory of the Covenanters, and the Ladies' rock, from which ladies viewed the jousts in the Valley Adjoining the cemetery on the south is the parish church, portions of which may have formed part of the first church, founded by David I Following the Reformation it was divided into two churches, but was restored to its original condition in 1935. The choir (the old East church) was added in 1494 by James IV, and the apse a few years later. At the west stands the stately battlemented square tower The nave (the former West church) is a transition between Romanesque and Gothic, with pointed windows. The crow-stepped Gothic gable of the south transept afforded the main entrance to both churches. The choir is in the Decorated and Perpendicular styles Within its walls Mary Queen of Scots was crowned in 1543, when nine months old, and in the same year the earl of Arran, regent of Scotland, abjured Protestantism; in 1544 an assembly of nobles appointed Mary of Guise queen-regent; on July 29, 1567, James VI was crowned, John Knox preaching the sermon, and in Aug 1571 and June 1578 the general assembly of the Church of Scotland met. James Guthrie (1612-1661), the martyr, and Ebenezer Erskine (1680-1794), founder of the Scottish Secession Church. were two of the most distinguished ministers. To the southwest of the church is Cowane's hospital, founded in 1630 by John Cowane, dean of guild, and now used as a guildhall. Adjoining it is the military prison Near the principal entrance to the esplanade stands Argyll's Lodging, erected about 1630 by the 1st earl of Stirling, Sir William Alexander, the founder of Nova Scotia. On his death in 1640 it passed to the 1st marguess of Argyll and later was made into a military hospital It is a fine example of a baronial town house. Broad street contains Mar's Work, the palace built by John Erskine, 1st (or 6th) earl of Mar, about 1570, according to tradition, out of the stones of Cambuskenneth abbey; the old town house, erected in 1701 to replace that in which John Hamilton, the last Roman Catholic archbishop of St Andrews, was hanged for alleged complicity in the murders of Darnley and the regent Moray; the town cross, restored in 1891, and the house which was, as a mural tablet says, the "nursery of James VI and his son Prince Henry." The Smith institute, founded in 1873 by Thomas Stewart Smith, an artist, contains a picture gallery, museum and reading room Carpet weaving and woollen spinning and manufactures are the staple industries, and ironfounding, carriage-building and agricultural implement-making are also carried on, in addition to furniture factories, cooperage and rubber works and confectionery works. There is some shipping from the small harbour, which is accessible only at high

Stirling, with Falkirk and Grangemouth, returns a member to parliament.

in 1839 from designs by Robert Stevenson, and below this again the milway viaduct. The castle crowning the hill is of unknown east of Stirling, is a thickly-wooded hill on the top of which stands age, but from the time that Alexander I died within its walls the Wallace monument (1869), a branch allower, with a valhalla in 1144 until the union of the crowns in 1603, it was hintmately containing butst of eminent Scotsmen. Castlement above, associated with the fortunes of the Scottish monarchs. It is on the left bank of the Forth, about 1 mi ENE of Stirling, was approached from the esplanach, on which stands a colosal state of founded by David I in 1147 for monks of the order of St August of Robert Bruce. The main gateway, built by James III, gives time. Several Scots parliaments met within its walls. At the access to the lower and then to the upper square, on the south Reformation Mary Queen of Scots bestowed it on the ste earl of side of which stands the palace, begun by James V (1540) and Mar (1562), who is said to have used the stones for his palace completed by Mary of Guise. The east side of the quadrangle is in Stirling All that remains of the abbey is massive, four-occupied by the parliament house, a Gothic building of the time storied tower, the west doorway and the foundations of some of of James III, now used as a barrack-room and stores. On the the walls. The bones of James III and his queen, Margaret of

Denmark, who were buried within the precincts, were discovered in 1864 and reinterred next year under a tomb at the high altar at

the expense of Queen Victoria.

Stirling was known also as Snowdoun, which became the official title of the Scots heralds The Romans probably had a station here In 1119 it was a royal burgh and under Alexander I was one of the Court of Four Burghs (superseded under James III. by the Convention of Royal Burghs) In 1174 it was handed over to the English in security for the treaty of Palasae, being restored to the Scots by Richard I. The earliest known charter was that granted in 1226 by Alexander III., who made the castle a royal residence. The fortress was repeatedly beseged during the wars of the Scottish Independence. In 3504 it fell with the town to the Scottish landependence. In 3504 it fell with the town to the Scottish single in 1314 that Scottish and the Scottish single in 1314 that Scottish single in 1314 that Scottish single in 1314 that III. In the Scottish single in 1314 that III. In 1314 in terms of his compact with Edward III., but the Scots regained it in 1339 in terms of his compact with Edward III., but the Scots regained it in 1339.

From this time till the collapse of Queen Mary's fortunes in 1568, Stirling almost shared with Edinburgh the rank and privileges of capital of the kingdom. It was the birthplace of James II in 1430 and probably of James III and James IV. In 1571 an attempt was made to surprise the castle by Mary's adherents, the regent Lennox being slain in the fray, and seven years later it was captured by James Douglas, 4th earl of Morton, after which a reconciliation took place between the Protestants and Roman Catholics It was occupied in 1584 by the earls of Angus and Mar, the Protestant leaders, who, however, fled to England on the approach of the king. Next year they returned with a strong force and compelled James VI. to open the gates, his personal safety having been guaranteed In 1504 Prince Henry was baptized in the chapel royal, which had been rebuilt on a larger scale. After the union of the crowns (1603) Stirling ceased to play a prominent part on the national stage. The privy council and court of session met in the town in 1637 on account of the disturbed state of Edinburgh In 1641 Charles I gave it its last governing charter, and four years afterwards parliament was held in Stirling on account of the plague in the capital, but the outbreak of the pest in Stirling caused the legislaters to remove to Perth. During the Civil War the Covenanters held the town, to which the committees of church and state adjourned after Cromwell's victory at Dunbar (1650), but in August next year the castle was taken by General Monk. In 1715 the 3rd duke of Argyll held it to prevent the passage of the Forth by the Jacobites, and in 1746 it was ineffectually besieged by Prince Charles Edward.

STIRLING NUMBERS, in mathematics In the year 1730 James Stirling, in his Methodus Differentialis interduced ino analysas two sets of numbers which, because of their uses in various branches of analysis, their properties, and the methods used in their computation, have continued to attract the attention of mathematicians.

One of the latest writers on the subject, Professor Nielsen of Copenhagen has named them "Stirling numbers of the first and second kind" in honour of their discoverer.

**Definitions.**—The Stirling numbers of order n of the first kind may be defined as the co-efficients in the expansion of

by the defined as the co-entral and the expansion of 
$$(1+x)(1+2x)\cdots(1+nx)=1+nS_1x+nS_2x^2+nS_2x^3+\cdots$$

in ascending powers of x, while the Stirling numbers of the second kind are found in

$$\frac{1}{(1+x)(1+2x)\cdots(1+nx)} = 1 - {}_{n}T_{1}x + {}_{n}T_{2}x^{2} - {}_{n}T_{4}x^{3} + \cdots,$$

also in ascending powers of x.

This definition immediately leads to the following theorems: (a) The  $P^{th}$  Stirling number of order n of the first kind is equal to the sum of the products of the first n integers taken P at a time without repetition.

(b) The P<sup>ih</sup> Stirling number of the second kind of order n is equal to the sum of the products of the first n integers taken P at a time with repetitions.

Stirling used the numbers now named after him as a tool for expressing  $v^n$  as a series of factorials

$$\begin{array}{l} x^2 = x(x-1) + x, \\ \tau^2 = x(x-1)(x-2) + 3x(x-1) + 3, \\ \lambda^4 = x(x-1)(x-2)(x-3) + 6x(x-1)(x-2) + 7x(x-1) + x, \\ \lambda^4 = x(x-1)(x-2)(x-3)(x-4) + 1xx(x-1)(x-2)(x-3) + x \\ - x^2 = x(x-1)(x-2) + x^2 $

The coefficients of the various factorials (1:1, 1:31, 1:67, 1:10.57:13) are the String numbers of the second kind. For about 150 years mathematicians considered it important to be able to express algebrate expressions in form of sequences of factorials. The result was a nch literature consisting of memoris dealing with the pecularities of this method of expression. In the year 1846 Weierstrass proved the general futility of this mode of notation, and since then the subject of "factorial notation" has slowly but surely been eliminated as a topic of discussion in mathematical hierature. At present it is used only in certain problems of finite summation, in theories of interpolation, and as nexample illustrating some of the uses of the Stringn numbers.

Applications.—George Boole in his treatise on the calculus of finite differences calls attention to the "system of numbers expressed by  $\Delta^n$  or differences of nothing)" without indicating whether he realized that these numbers were already used by Strling 'The formula given by Boole for  $\Delta^n$  or may well be used for the calculation of the above mentioned coefficients T, i.e., the Strling numbers of the second kind.

$$\frac{1}{n!} {}_{n}T_{m-n} = n^{m} - \left(\frac{n}{1}\right)(n-1)^{m} + \left(\frac{n}{2}\right)(n-2)^{m} - \left(\frac{n}{3}\right)(n-3)^{m} + \cdots$$

The Stirling numbers of the second kind (T) also appear in the expansion of  $(e^{\tau}-1)^{\rho}$ . Thus,

$$\begin{array}{c} \frac{1}{21}(s^p-1)^2 = \frac{s^3}{21} + \frac{sT_1s^2}{31} + \frac{sT_2s^4}{4^4} + \cdots \\ \frac{1}{31}(s^p-1)^2 = \frac{s^3}{21} + \frac{sT_1}{4^4} + \frac{sT_2s^4}{51} + \cdots \\ \frac{1}{4!}(s^p-1)^p = \frac{s^2}{2^p} + \frac{sT_1}{(b+1)!} s^{p+t} + \frac{sT_2}{(b+2)!} s^{p+t} + \cdots \end{array}$$

Formulas.-Of the recurring formulas the most important are

$$_{n+1}S_p = _nS_p + n \cdot _nS_{p-1},$$
  
 $_{n+1}T_p = _nT_p + n \cdot _{n+1}T_{p-1}.$ 

Of the independent formulas developed by various writers, none is suitable for practical purposes, but theoretically the following formulas which appear in a work by Ettinghausen (1826) are important:

$${}_{n}S_{p}=\sum \frac{(n+1)!}{a!\,b!\,c!\cdots x^{a}\,2^{b}\,3^{a}\cdots}$$

for all integral values of a,b,c . . . satisfying the equations:

$$a+b+c+\cdots=p+1,$$
  
 $a+2b+3c+\cdots=n+1,$ 

$$_{n}T_{p}=\sum \frac{(n+p)!}{a!b!c!\cdots i^{a}(2!)^{b}(3!)^{c}\cdots}$$

for all integers satisfying the equations

$$a+b+c+\cdots=p$$
,  
 $a+2b+3c+\cdots=n+p$ .

Relations between the S's and the T's are given by

The second formula is evidently obtained from the first by interchanging the T's and the S's It has also been observed (Amer. Math. Monthly, 1928) that the Striling numbers of the first kind can be obtained by performing the algebraic divisions,

$$\frac{2+x}{(1-x)^{\delta'}} \frac{6+8x+x^2}{(1-x)^7}, \frac{24+58x+22x^2+x^6}{(1-x)^9} \dots$$

while the Stirling numbers of the second kind appear in the quotients of

$$\frac{x+2x}{(x-x)^9}$$
,  $\frac{x+8x+6v^2}{(x-x)^9}$ ,  $\frac{x+22x+58x^2+24x^3}{(x-x)^9}$ ...

The Stirling numbers have many important relationships to the Bernoulin numbers (q, v). Bother numbers (q, v), and the tangential coefficients, and there are numerous formulas connecting them. In fact, there is a way of regarding the Bernoulin numbers as a species of Stirling numbers; that is  $(e^{\omega}-1)^2$  always gives, when expanded, Stirling numbers, and when we let  $\pi=-1$ , we obtain a well-known expansion giving the Bernoulli numbers.

The consideration of  $(e^x - 1)^{-n}$  leads to what may be called ultra-Stirling numbers, a subject which, like the ultra-Bernoulli and ultra-Euler numbers has been very little studied.

and ultra-buier numbers has been very utile studied.

STIRLINGSHIRE, midland county, Scotland, bounded north by Perthshire, north-east by Clackmannanshire and the Firth of Forth, south-east by Linlithgowshire, south by Lanarkshire and the detached part of Dumbartonshire and south-west and west by Dumbartonshire; land area 288,332 ac., or 450.5 sq mi. In the northwest the Grampians end in Ben Lomond (3,192 ft ) The centre is occupied by the Lennox hills The oldest rocks are the Dalradian schists in the north-west beyond a great fault which runs from near the bottom end of Loch Lomond in a north-easterly direction across Scotland. On the south-eastern side of the fault are the conglomerates and sandstones of Lower Old Red Sandstone age, followed by the Upper Old Red series Then follows the Carboniferous system occupying the rest of the county. The true coal-measures are well-developed between Grangemouth and Stenhousemuir and about Falkirk. Intrusive sheets of basalt have penetrated the Carboniferous rocks and are quarried for road metal; Abbey Craig and Stirling Castle hill are formed of one of the more important of these intrusions. Much boulder clay covers the older rocks and an interesting blue marine clay is found beneath it in the Endrick valley The Carse of Stirling is overlaid by the muds and sands of the 50-ft. raised beach; and traces of the 100-ft. beach also are found.

The chief river is the Forth, which forms most of the northern boundary. The other important streams are the Carron, rising in Campsie fells and slowing to the Forth at Grangemouth; the Endnck, which, rising in Furty hills, emplies itself into Loch Lomond; the Kelvin, which, from its source in Kilsyth hills, slows southwest to the Clyde at Glasgow after a run of 2 z m.; and the Avon, rising in the detached portion of Dumbartonshure, and the Avon, rising in the detached portion of Dumbartonshure, and the Avon, rising in the detached portion of Dumbartonshure, and the Avon, rising in the detached portion of Dumbartonshure, and the Avon, rising in the detached portion of Dumbartonshure, and are are a reason of the Avon, rising in the detached portion of Dumbartonshure, are are, which, like Lock Katrine, and Loch Arklet, in the worth-west area, which, like Lock Katrine, rovides part of the water supply of Glasgow. The Forth and Clyde canal crosses the south-eastern corner of the county from Grangemouth to Castlecary.

History and Antiquities—The wall of Antonius, built by Lollius Urbicus, in A.D. 149, connecting the Forth and Clyde, passed through the south-east of the county, in which it is locally known as Graham's Dyke. At Castlecary and Camelon many relics have been found. The Camelon causeway ran eastwarfs from Castlecary and crossed the rampart at Camelon, whence it proceeded northwards to Stiffing and the Forth, where there was a

station near the present bridge of Drip Thence it crossed the river to Keir and Dunblane in Perthshite After the withdrawal of the Romans the county once more fell into the hands of the native inhabitants, who, however, gradually retired before the advance of the Saxons and Scots By the time of Malcolm Canmore (d 1003) the lowland area had become settled, but the highland tract remained a disturbed and disturbing region until the pacification following the Jacobite rising of 1745-6 The county played a conspicuous part in the struggle for Scottish independence, being particularly associated with many of the exploits of Sir William Wallace and Robert Bruce. The three great battles of the independence were fought in the shire-Stirling Bridge (1207), Falkirk (1208), Bannockburn (1314) James III was stabbed to death in a cottage in the village of Milton after the battle of Sauchieburn (1488), but apart from the disastrous defeat of the Covenanters at Kilsyth (1645) and the transitory triumph which Prince Charles Edward won at Falkirk (1746), the history of the shire practically centres in that of the county town

Agriculture and Industries.—The arable soils are of two kands, locally distinguished as 'crase' and "dryfield," the rest of the land being composed of pasture, moor and peat. The "carse" cetteds along the valley from Buchlywe to the eastern boundary. The soil consists of the finest clays, without stones, but interserved with strate of marine shells. It has been largely stripped of the overlying peat, and by draming, subsoil ploughing and the so of lime has been converted into a rich soil, especially adapted for wheat and beans. The "dryfield," which occupies the valleys and the higher ground bordering the carse, is fertile and sudded for potatoes and turnips, of which there were 5,880 ac in 1938. Oats (14,67 as 2) and wheat (2,997 ac) are the chief grain crops. Beans are also grown. The cattle are comparatively few, but sheep, chefty Black-faced, are rused. The average size of the 1,511 holdings in 1938 was 70½ ac, but over half were of 50 ac and were Birches grow on the lower slopes of the mountains in Buchanan and Drymen, and oaks on the banks of Loch Lomond. Larch and Scots fir are the leading trees in modern plantations.

The coalfield of the south-east supplies the staple industry, and coal is also mined in the east, near the Forth and Clyde canal Iron ore and fireclay are also obtained, while granite, limestone and sandstone are quarried The ironworks at Carron near Falkirk are important and nails are made at St. Ninian's and elsewhere. Woollens are manufactured at Stirling, St. Niman's and Bannockburn; calico-printing and bleaching are established in the south-west, especially at Lennoxtown and Milton, and there are chemical works at Falkirk and Denny, Tanning, iron-founding, paper-making, brewing and distilling are carried on at different places, and shipbuilding at Grangemouth, the chief port, southern and south-eastern districts are served by the LNER from Edinburgh to Glasgow (via Falkirk) and the L M S.R. from Glasgow to Stirling (via Larbert), while branches connect Grangemouth. Denny and other places with the through-lines. One L.N E line crosses the shire, mostly in the north, from Stirling to Balloch, and another goes from Glasgow to Aberfoyle.

Population and Administration.—Fop (est :038) 1733-410. In 1931 Gaelic and English were spoken by 1.039 persons. Falkirk (est. 1938 pop. 38,173) and Stirling (23,552) are large burgls, the small burgls being Grangemouth (13,710). Kileyth (3,763). Denny and Dunlpace (5,995), and Brage-of-Allan (3,890). There are three county districts. The shire returns a member to parliament with Clackmannan, and Stirling, Falkirkh and Grangemouth one member Stirling is the only royal burgl. The shire forms a sherifidom with the counties of Dumbarton and Clackmannan, but there is a resident sherific substitute at Stirling and another at Falkirk. The shire is under school board jurisdiction, and there are high schools at Stirling and Palkirk.

and americal are assist. The starter is tunder school other jurisuition, and there are high schools at Strings and Palkitch poet and scholar, whose original name was Goran Lulja, was born at Wike in Dalecardia on Aug. 7, 1958. He took his degree at Gersfrewid, and spent some years in travelling over every quarter of Europe. Gustavus Adolphus gave him a responsible post at Dorpat in 1630, and raised him next year to the noblity. After the kings death, Christian attached him, as a kind of poet laureste, to fee death, Christian attached him, as a kind of poet laureste, to fee

court in Stockholm His property lay in Livonia, and when the Russians plundered that Province in 1656 the poet, who was in temporary disgrace at the court, was reduced to extreme poverty for two or three years He subsequently became judge at Trondhjem, member of the council of war (1661) and president (1667) of the College of Antiquities at Stockholm He died at Stockholm on April 22, 1672 His greatest poem Hercules (pt 1653) is a didactic allegory in hexameters, written in very musical verse, and with almost Oriental splendour of phrase and imagery Brollops-Besvars Ihugkommelse, a sort of serio-comic epithalamium in the same measure, is another brilliant work masques, Then fangne Cupido (Cupid Caught) (1649), Freds-aft (The Birth of Peace) (1649), and Parnassus triumphans (1651), were written for the entertainment of Queen Christina He can scarcely be said to have been successful in his attempt, in the first two of these, to introduce unrhymed song measures

Stjernhjelm was an active philologist, and left a great number of works on language, of which only a few have been printed. He also wrote on history, mathematics, philosophy and natural science, pro-ducing original and valuable work on every subject he attempted, There is a full list of his writings in the Svenskt biographiskt Lexikon,

vol xv (Uppsala, 1848) STOA, in Greek architecture, a long open building with the roof supported by one or more rows of columns parallel to the back wall A row of rooms may open from the rear of the colonnade, a second story is often added Stoae surrounded the market places and later the sanctuaries and served for nearly all public and private business, commercial and legal, as well as for public promenade Athens, Corinth, Delos and the Asia Minor cities ofter good examples (L T SE)

STOBAEUS, JOANNES, so called from his native place Stobi in Macedonia, the compiler of a valuable series of extracts from Greek authors. Of his life nothing is known, but he probably belongs to the latter half of the 5th century AD From his silence in regard to Christian authors, it is inferred that he was

not a Christian.

The extracts were intended by Stobaeus for his son Septimius, and were preceded by a letter briefly explaining the purpose of the work and giving a summary of the contents From this summary (preserved in Photius's Bibliotheca) we learn that Stobaeus divided his work into four books and two volumes. In most of our manuscripts the work is divided into three books, of which the first and second are generally called Έκλογαι φυσικαι και ήθικαι (Physical and Moral Extracts), and the third 'Ανθολόγιον (Florilegium of Sermones)

As each of the four books is sometimes called 'Ανθολόγιον, it is probable that this name originally belonged to the entire work; the full title, as we know from Photius, was Έκλογων ἀποφθεγμάτων ὑποθηκῶν βιβλία τέτταρα (Four Books of Extracts, Sayings and Precepts). The modern arrangement is somewhat arbitrary, and there are several marked discrepancies between it and the account given by Photius

The introduction to the whole work, treating of the value of philosophy and of philosophical sects, was lost with the exception of the concluding portion; the second book is little more than a fragment, and the third and fourth have been amalgamated by altering the original sections. From these and other indications it seems probable that what survived is only an epitome of the original work, made by an anonymous Byzantine writer of much later date. The didactic aim of Stobaeus' work is apparent throughout. The first book teaches physics-in the wide sense which the Greeks assigned to this term-by means of extracts. It is often untrustworthy; Stobaeus betrays a tendency to confound the dogmas of the early Ionic philosophers, and he occasionally confused Platonism with Pythagoreanism. For part of this book and much of the second book, he depended on the works of Aetius, a peripatetic philosopher, and Didymus.

The third and fourth books, like the larger part of the second, are concerned with ethics; the third, with virtues and vices in pairs; the fourth deals with more general ethical and political subjects, frequently citing extracts to illustrate the pros and cons of a question in two successive chapters.

In all Stobaeus quotes more than 500 writers, generally begin-

ning with the poets, and then proceeding to the historians, orators, philosophers and physicians

It is to him that we owe many of our most important fragments of the dramatists, particularly of Euripides.

Editio princeps (1609), Eclogae, ed T Gaisford (1822), A Meineke (1866-64), Floridegum, ed T Gaisford (1850), A Meineke (1857-1857), C Wachsmuth and O. Hense (1884-94, and 1909)

STOBO, ROBERT (1727-c. 1772), Scottish-American soldier, born in Glasgow, Scot, emigrated to Virginia where he became a merchant and an officer in the militia. He fought in the French and Indian War Held as a prisoner by the French, he escaped in 1759 and joined the successful English assault on Ouebec. Memours of Major Robert Stobe of the Virginia Regiment was published in London in 1800 Stobo is generally considered to have been the basis for the character Lismahago in Tobias Smollett's The Expedition of Humphry Clinker (1771)

STOCK, FREDERICK AUGUST (1872-1942), U.S conductor and director of the Chicago Symphony orchestra for 37 years, was born on Nov 11, 1872, in Julich, Ger

From his father, a bandmaster, he received his early musical training, and he later studied violin and composition at the Cologne conservatory.

Theodore Thomas, founder and conductor of the Chicago Symphony orchestra, discovered Stock when he was a violinist with the Cologne orchestra and invited him to Chicago to join the new orchestra in 1805. He made his debut there as a viola player and six years later became Thomas' assistant and associate conductor

Shortly after the Chicago symphony moved into its new quarters at Orchestra hall in 1905 Thomas died and Stock became his successor He directed from the Orchestra Hall podium for the next 37 years, except for a short period during World War I when public opinion forced his resignation until he could obtain final U.S. citizenship papers

Stock was said to have introduced more scores by U S composers than any other conductor in the country He composed three overtures, two symphonies, a violin concerto, a 'cello concerto, a Festsval March and Hymn to Liberty

He died in Chicago on Oct 20, 1942.

STOCK. The modern business company producing goods or rendering services of an economic nature must initially be supplied with assets-money, property, equipment, materials, etc.which will enable it to perform its functions. The portion of the assets supplied by persons who invest their money at the risk of profit or loss is called the company's capital, and those who provide it are called members of the company. In order that many persons may have an opportunity to invest their funds in such a company, its capital, as authorized by its charter, is resolved into a stated number of shares which in the United States are called capital stock and in England are called capital shares, or, more rarely, company stock.

If the members of the company operate under a partnership agreement, any one of them may be held liable to satisfy all of the company's creditors out of his private estate and is said to have unlimited liability. The laws of the western democracies, however, permit those who desire to undertake a business as a group or company to apply to a designated official for a charter of incorporation. This, when granted, permits them to act as a single legal person or body corporate in business relations with others within such limits as are set forth in the charter and laws. liability of each member of the company to creditors is thereby limited to the sum that he agrees to contribute to the chartered company's capital.

The practice of supplying public and private bodies corporate with needed money in the form of funds subscribed by many persons can be traced back to the middle ages in western Europe. From the beginning of their use a characteristic of funds of this type has been the fact that the subscribers acquired collectively as well as severally given bundles of legal rights, powers, privileges, immunities, liabilities and duties with respect to the user of the fund, themselves, and other persons These rights are private property whose ownership is vested in the subscriber or subsequent holder.

416 STOCK

At first the subscriber to such a fund received no written instrument as evidence of his rights and had to rely entirely upon the books and records of the user of the fund to prove his ownership. But by the close of the 17th century it became customary to give him a certificate that identified the fund, the amount of his participation and the payments to which he was entitled. The transferral of his rights in the fund to another by giff, sale, etc, was then easily accomplished by executing an assignment of the instrument which, in moder times, a generally held to be necotiable.

Trading in such bundles of rights was greatly facilitated by the use of transferable certificates These came to be distinguished from one another not only by the nature of the obligation assumed by the user of the fund, but also by the nature of the payments which the holder of rights was entitled to claim Thus in England and its American Colonies in the early part of the 18th century certificates representing shares in the proprietary capital of a chartered company risked at profit and loss were already called shares of joint stock or simply stock, those that entitled the owner to claim a periodic payment of interest and repayment of a principal sum at some future date were usually called obligations or debentures, and those that entitled him to claim annually only a given sum of money either for a limited number of years, for life, or for an indeterminate period of time were called annuities The persons who acted as brokers and dealers in such bundles of rights were called stock brokers or jobbers, and the market in which they operated came to be called the stock exchange Thus at one time the word stock, when used in its broadest sense, signified all sorts of subscribed funds and rights therein However, early in the 19th century it had already become the practice not only in England but also in the United States to employ the term securities to signify all varieties of such rights and to reserve the word stock to signify only a particular kind of security Today the English concept of stock is quite different from that in use in the United States.

### UNITED STATES

In the United States the term stock is used as a term of law and finance. It signifies a chartered company's proprietary capital that is divided into shares whose owners are members of a body corporate. Collectively, therefore, they own the business carried on by the company or corporation and as owners may obtain a profit or sustain a loss. The extent to which a member of the body corporate participates in the conduct of its affairs and shares in its profits or losses is determined by the number and variety of the shares that he owns. Because it is a constituent part of a capital stock, the share is also generally called stock and the certificate reciting ownership of such shares is called a stock certificate During the last decade of the 18th century, however, shares in the funded debt of the United States and throughout the 19th century in the funded debt of New York city were called stock. But shares in a loan fund, whether for use by federal, state or municipal governments or private companies, are now almost invariably called bonds.

At common law any group of persons may contribute to a fund to be used for bissines purposes under a partnership agreement, but any one of such persons may be sued personally by creditors of the partnership for unpaid debts. However, when such a group of persons is constituted a body corporate a separate legal personality is conferred upon them collectively. It is the legal person with whom creditors have to deal and to whom primarily they must look for sustfaction of their claims. The extent to which the individual member of the body corporate is liable is determined by the laws of the state that has granted the privilege of incorporation. The procedure employed to provide such a body corporate with capital rudnes is regulated by state as well as federal law.

Capital Stock.—The laws of the several states provide invariably that the authorized capital stock of a business corporation shall be reloved into a given number of shares and that these may be further resolved into classes whose bundles of legal rights may differ from one another. Prior to 1912 an ascribed nominal or par value was given to the share. However, while some states missted upon a substantial nominal value, such as \$700, others required less and some set on ominimum limit, even authorizing shares with par value of a tenth of a cent Incorporation taxes and licence fees in other states were based on this par value. As a result, after 1912 most state laws were amended to give incorporators a choice between par value shares and shares of no-par value, but at the same time a minimum paid-in capital with which the company might begin business was prescribed

Subcerbers to capital stock must pay in full the par value of the share or the stated value that has been ascribed by directors of the company to the share of no-par value or remain liable to creditors of the company for the unpaid balance. For this reason, it is the practice to issue definitive share certificates only after such payments have been made and to note thereon that the shares are "full pad and nonassessable." When more than the par value is paid the excess is called a paid-in capital surplus. In the case of no-par value shares any sum in excess of the minimum capital prescribed by the charter may be designated as paid-in capital surplus.

Only enough stock need be subscribed and paid in to meet the minimum capital requirement set by the charter. In consequence, therefore, the corporation may have a paid-in capital stock that is less than its authorized capital stock. When it acquires as assests shares it once had susued, these are called treasury stock and the

issued remainder is outstanding stock.

Powers and Rights of Stockholders.—Collectively the stockholders of record accept the charter, adopt a seal, adopt by-laws, petition the state to amend the charter or dissolve the body corporate, and dispose of corporate assets, but they must place the management of their business affairs in the hands of a board of directors whose membership they elect and may remove. This board appoints a president, one or more voce-presidents, a secretary, a treasurer and a legal representative as officers of the company to administer its affairs. The directors also determine within appart to administer its affairs. The directors also determine within disposition is to be made of the surphis and earnings, and declare dividends.

When there is only one class of stock authorized and outstanding, the bundle of legal rights middent to ownership of one share may be summarized as follows: to receive notice of meetings of the body corporate; to attend these meetings in person or by proxy; to vote in person or by proxy on any resolution that is prosed, especially for election of directors, to share in distributed earnings when and as declared by the board of directors (dividends); to share in capital on liquidation, to receive financial reports and an accounting from directors; to petition a court for an order to inspect the company's books or to protect the company or a group of participants against inequities or acts ultra vises (exceeding their legal powers); to have an opportunity to subscribe to additional shares pror to their offer to the public; and to dispose of shares by girt, sale, hypothecation or otherwise

Classes of Stock—To resolve the capital stock of a company into classes of sherse whose rights, powers and privileges differ from one another has long been a U S as well as an European custom. The rights that usually are modified in one way or another to accomplish this purpose are these. (1) to vote in the election of directors, (3) to share in the earnings, and (3) to share in the assets on dissolution. Although modification usually results in placing one class of stock in a favoured position relative to basic stock with respect to one or more of these three rights, this is not necessarily the result.

Common Stock.—When the authorized capital stock of a corporation consists of only one class of shares, these usually are acid common stock. A favoured class may be distinguished from it solely by the voting power conferred upon it. Thus when power to elect the board of directors is vested in one class of common stock and is denied another, these classes usually are called voting and nonvoting common stock, and may be differentiated by means of prefixing such letters as A or B

Preferred Slock—When a stock is placed in a favoured position with respect to right to earnings it is usually called preferred stock. This is so even though a favoured position is ascribed to it also with respect to a share in assets on dissolution and in voting for directors, Suth stocks have been devised to provide a security

STOCK 417

that has some of the features of a bond without giving the holder thereof power to obtain a judgment against the company for failure to fulfil its promises. This end is effectively attained when the security is part of the capital stock of the issuing company

While a bond is a promise to pay a sum on a given day and if not paid permits the holder to obtain a judgment satisfiable out of the capital of the issuing company, such a promise can be made to the holder of stock subject only to important conditions. In the first place he cannot receive repayment until all creditors have been paid, not can he be paid out of capital stock except by liquidation. For this reason a preference to share in assets before any distribution is made to holders of less favoured stock usually becomes effective only upon dissolution. However, it is of course scrings which could be used for tredemption of a preferred stock. A preferred stock of the latter type is called a redeemable preferred stock of the latter type is called a redeemable preferred stock.

Similarly the promise to pay interest on a debt on a due date permats the cliamant to obtain a pudgment ordering its payment out of capital if necessary and usually also makes the principal due and payable at once on failure to keep the promise On the other hand, the holder of a stock that is preferred as to dividends has no such power to enforce payment. Dividends are payable only when and as they are declared by the board of directors out of "carnings" or surplises net earnings" as the phrases run. When there are no earnings they may not be paid. But even when earnings are available payments may be withheld provided the promise of sundry claimants as observed. When dividends are declared not not provided the promise of such payments and the provided the promise of such payments and payments are available sayments and such payments are available sayments and such payments are available sayments. The control of the provided has provided the promise of the payments are available to the payments and the provided the promise of the payments are available to the payment and the payments are available to the payment are available to the payment are available to the payment and the payment are available to the payment are available to the payment and the payment are available to the payme

On the whole, it is clear that common stockholders, who are in the least favoured position, run the greatest risk of loss and cannot share in profits until holders of stock in more favoured positions have been satisfied. The theory therefore has been advanced that common stockholders should have power to elect a board of directors who while managing the busness for them must satisfy others before satisfying their electors. However, such an arrangement would give no protection to holders of noncumulative preferred stocks (see below). Some, therefore, have conditional or unconditional power to elect the board of directors, others have votting rights per share such as are enjoyed by common stock and still others have no votting rights at all.

Where there are several classes of preferred stock whose order of preference is established they are usually identified as first, second, thurd, etc., preferred stock, or as A, B or C preferred stock. Even within the limits set forth above many variations in the legal rights that constitute preferred stock are possible, and additional rights and protections may be introduced. For this reason it is well to describe some of the types that have such spocial features.

Noncessulative and Cunstilative Cilims: to Dividents.—It is common practice to ascribe a dividend presumed to be paid annually to a preferred stock as a given per cent of par value, or as a given sum when the share has no par value, before any dividend may be paid to common stock. When a dividend is not declared in any given year on such a preferred stock, even though there are earnings, it is lost to the stockholder, and the stock is cailed non-cumulative preferred. At time it is therefore protected by giving the holders the right to elect a board of directors to serve until a dividend has been paid. However, a better means of preventing remaining unpud shall have prior claim upon future earnings and must be paid in full before a dividend may be paid to common stock. A stock with this type of claim to dividends is called a cumulative preferred stock.

Additional Participation in Dividends—Unless it is otherwise specified, a preferred stock does not share in any earnings that remain for distribution after its ascribed dividend has been paid, but specific provisions may be inserted that give it some surfights. For this reason a distinction is made between participations of the provision of the preference of the provision of th

ing and nonparticipating preferred stocks.

The terms on which a preferred stock is to participate in any distribution of earnings that normally would go to common stock must be clearly set forth in the charter or in the resolutions that create the preferred stock Its participation is said to be "simple" when both common and preferred stock share equally per share in dividends out of earnings that remain after the preferred stock has received its regular ascribed dividend and a like payment per share has been made to common stock Usually a preferred stock with such rights is called participating preferred stock. When preferred stock participates before common has received payments equal to the regular dividend of the preferred stock it is said to participate "immediately" Participation may also be limited to given percentages or sums, according to priorities that are allocated to several classes of preferred and common stocks, which are then said to participate "specially" Such participating features, however, are much more common in England than in the United States

Redeemable Stock.—Only when the charter of the company so provides may it redem a class of stock and remain in operation Under no circumstances is redemption at the option of the holder, for such a right would put him in the position of a creditor. Redemption must remain optional with the company. The provision creating the stock may provide that it may be redeemed in part by call on and after a given date, or that it must be redeemed, if at all, in whole. The price at which it may be redeemed must also be stated. While the privilege of redemption at par value is more common than redemption at a premium, the latter arrangement does not have such a depressing effect on the market value of the shares.

Consentible Stock.—Holders of stock are sometimes given the privilege of converting it into another form of security at their option. As a rule conversion results in the surrender of some priority rights. Thus preferred stock is usually convertible only into common. The charter of the company may set forth the conditions and terms under which a given stock is convertible into another, but if enough unissued common stock is available an offer to convert preferred stock into common may originate with the directors. When a preferred stock is nonparticipating the conversion privilege is often of value because when dividends paid titled its holders can obtain the higher dividend rate by converting their shares into common.

Conversion of nonvoting preferred into voting common and redemption of voting preferred has often played a role in struggles to elect boards of directors because the number of voting shares could be increased by conversion and decreased by redemption.

Protected Preferred Stock—When the company has a preferred stock outstanding, the directors may, at their option, set up a reserve out of earnings that can be drawn upon to pay dividends to the preferred stock in years when earnings may be insufficient for that purpose. Such a requirement may also be set forth in the charter provision that creates the preferred stock. Under these conditions a preferred stock is said to be protected.

Guaranteed Stocks.—When one company for a valid consideration agrees to be responsible for the payment of dividends on stock issued by another company, such stock is said to be guaranteed, Guaranteed stocks originate almost entirely among railway companies. The consideration received by the guarantor usually a long-term lense of the issuer's entire property, subject to a rental payment that is sufficient to pay interest and amortization on the lessor's outstanding bonds and a given dividend per share its outstanding stock. Usually the guaranteed stock has been subsequently purchased in the market by the guarantor.

Stocks with Rights.—The holders of common stock have a premptive right to an opportunity to subscribe to new issues of the common and also often of preferred stock before these are offered to others or the public. When such an offer is made to them it is usually at a price that is below the market price of like shares and they are said to have rights to a privileged subscription. While the right to this privileged subscription is open the outstanding stock that possesses it is quoted in the market with "rights-on." holders entitled to them the shares are quoted "ex-rights" Finally when the privilege for making use of the warrants has expired, the stock is again quoted without any additional notation Canada generally follows US practice because the bulk of its company capital comes from its southern meighbour.

#### GREAT BRITAIN

In England since 1862, the term stock has signified a subscribed fund, resolvable into parts as small as pounds, shillings and pence, for use as corporate capital or a loan. The opportunity to subscribe acts small sums was devested morder that persons of modest means might invest as much or as little in money as they deem desirable, for otherwise they would have to commit themselves to subscribe to indivisible units which in the case of loan funds are boads, usually of an ascribed value of foco, or in the case of proprietary capital shares of a par value of not less than \$I\_{TO}\$, but usually also of fico. The subscriber to, or subsequent purchaser of, participation in such a fund receives a certificate that usually sets forth briefly the purpose for which the fund has been subscribed, the rights of the holder and the number of pounds, shillings and pence in the fund that it represents

The pnec that £100 of stock will bring in the market naturally depends upon the net return per annum to the holder and the pnec that other investors are willing at the time to pay for it. Its price is therefore usually quoted at £100 as par or a penetralge over or under that figure. While the price of bonds is quoted in the same way, the price of shartes in the capital of a company is quoted in pounds, shillings and pence per share because these may be issued and traded when only part paid.

The bodies corporate that make use of funds of stock can be either public or private. In the fanacial markets public funds are classified as either "government" or "municipal" and each of these categories is resolved into British, colonial and foreign subclasses. When they are used by chartered private companies these funds are either loans called debenture stock or constitute a part of the capital of the company. When they are of the latter type they are called company stock. Company stock is convettible into full pand shares and vice verse and may even have voting rights.

STOCKARD, CHARLES RUPERT (1879—1939), U.S. biologist and anatomut, was born in Washington country, Miss. on Fb. 27, 1797. He was educated at the Massistipp Agricultural and Mechanical college and at Columbia university, where he received his doctorate in 1906. He was granted his medical degree by the University of Wurzburg in 1922. After completing his studies at Columbia, he joined the faculty of the medical college of Cornell university and was professor of nantomy there from 1911 until his death. Stockard attracted international attention by his morphological investigations and by his experimental production of monstrotities. He died in New York city on April 7, 1939.

STOCKBRIDGE, a town of Berkshire county, Massachusetts, U.S.A., on the Housatonic river, served by the New York, New Haven and Hartford railroad. Pop. (1950) 2,311; (1940) 1.815. It is a summer and autumn resort and a region of historic interest. Within its area of 24 sq mi. are Lake Mahkeenac or Stockbridge Bowl, Ice Glen (where caverns are lined with ice even in midsummer) and Monument mountain (1,710 ft.). Most of 'Tanglewood," home of the Berkshire Symphonic festival and the Boston Symphony orchestra's Berkshire music centre, is in Stockbridge, overlooking "the Bowl." In 1736 a plantation 6 mi, square (including the present town of Stockbridge) was laid out for the Mohican Indians who had come to the Housatonic valley from the west bank of the Hudson when white settlements began to encroach on their territory, and among whom John Sergeant had established a mission in 1734. In 1739 this "Indian town" was incorporated as the town of Stockbridge. The Indians had a school and a church with Jonathan Edwards in charge from 1750 to 1758. Many of them fought on the American side during the Revolution. In 1783-88 nearly all of them moved to New York, and by 1829 most of them had gone to Wisconsin.

STOCKBROKER, an agent who deals in stocks and shales He need not be a member of any recognized stock exchange, nor of an association of stock exchanges. He need not confine his energies to dealing in only such securities as those which are quoted in a stock exchange. The broken member of the London stock exchange is an agent for the buying and the selling of stocks and shares of any description, and his status is kept stript clear from that of a stock)obber, so far as the London stock exchange rules are concerned

The broker, if a stock exchange member, acts as an agent, seldom as a principal. He does not as a rule buy from a client nor sell to a client. He buys or sells on behalf of the client, and takes a certain amount of commission, the extent of which is laid down in stock exchange rules for members of the stock exchange as his remuneration for doing the business. He is not allowed, in the London stock exchange, to buy roo shares from a client say at  $L_5$  and sell them simultaneously to another client at  $L_5$  5°. To do this would be acting as a principal, the part assigned to a stockpobber

The young man who would become a broker in a London stock exchange usually finds that a good way of achieving his end is to obtain a seat in the office of a stock exchange firm, entering either as a junior or a clerk, and gradually working his way through the various stages which stand between the outsider and the fullblown member of the stock exchange He can become a member without delay, provided he is not less than 21 years of age and is able to obtain three sureties who will guarantee, in the sum of £500 each, the fulfilment of his obligations for four years from the date of his admission. If the candidate has served as a clerk in the stock exchange for four years previous to the lodging of his application form, two sureties, or recommenders, only are required, who must each enter into an obligation as above mentioned. but for £300 apiece The scale of the London stock exchange charges, both for admission fee and annual subscription, is substantially less in the case of the experienced man. The candidate for membership must obtain with a very small proportion of exceptions a nomination, the price of which varies considerably, When first created several years before World War I, a nomination reached the value of £700 After that war, nominations became at one time practically valueless. Several are known to have changed hands at £5 apiece After that an improvement set in, and the price rose to about £2,000, but it fell heavily during World

Strict rules govern the stockbroker in the London stock exchange, and some of the provincial stock exchanges have modelled their rules upon them. He must be a Brutish subject; he has to apply for re-election every year, he must state whether he intends to act as broker or jobber, he must not be a principal in any business other than that of stock exchange, nor must he be member of, or subscribet to, any other institution where dealings in stocks and shares are carried on. His wife, also, must not be engaged in business.

His duties bring him into contact with his clients, and with brokers and jobbers alike, and he acts as agent between the public on one side and members of the stock exchange on the other He is required to have a general knowledge of all the markets in which he is called upon to deal, and he must be prepared to give reasonable answers to the hundreds of questions with which he is plied on all sorts of subjects.

The broker's life is more arduous than that of a jobber, mvolying longer hours and the exerces of unlimited patience, for he has to make allowance for the fact that the majority of his clients do not grasp the intimate details of what is after all a very technical business. His first daily duty, after having digested the financial business. His first daily duty, after having digested the financial business. His first daily duty, after having digested the financial business. His first daily duty, after having digested the financial business. His first daily duty, after having digested the financial business. His first daily didentify a first state and the stock exchange for execution when the markets open. He, the broker, buys or sells War loam in one market, Kaffirs in another, artificial silks in another, going through various parts of the house that have no strict delimitations, one market impraging on the next. The men round the markets who deal in specialized stocks and shares are the jobbers, and to them the broker proceeds, expecting that he will be able to get a double price made to hum, at the

higher of which he can buy and at the lower of which he can sell without the jobber knowing in advance which of the two courses the broker will take in executing his client's order

In the spring of 1939, as a result of the losses sustained for many previous years by members of the public through the malpractice of what are called bucket shops, parliament passed an act to provide for regulating the business of dealing in securities. It is called the Prevention of Fraud (Investments) act, 1939 Section I lays down that no person shall, on or after the appointed day. carry on or purport to carry on the business of dealing in securities except under the authority of a principal's heence, that is to say, a licence under this act authorizing him to carry on the business of dealing in securities. The servant or agent of any such person is required to hold a representative's licence authorizing him to deal in securities as a servant or agent of the holder of a principal's licence These restrictions do not apply, the act lays down, to a member of any recognized stock exchange or recognized association of dealers in securities The Bank of England and ceitain other bodies and persons are exempted from the restrictions imposed by this act Contravention of its provisions involves liability for heavy penalties Issue of the licences, the act provides, is in the hands of the board of trade and a prescribed fee, together with a deposit of £500, is required for a principal's licence which will be valid for one year Fraudulently inducing persons to invest money is an offense that carries liability to penal servitude for a term not exceeding seven years, and restrictions are placed upon the distribution of circulars relating to investments, The restrictions do not apply to prospectuses and other documents permitted by the board of trade. The act was partly suspended after the outbreak of World War II

United States—A stockbroker is an agent who deals in stocks, bonds and other securities either on or off an organized exchange. Legally, the relationship between the broker and customer is not only that of agent and principal but becomes that of creditor and debtor and that of pielage and piedgor when the customer purchases on margin and the broker furnishes the required additional funds secured by collateral. The relationships between brokers and their customers are governed by the various and differing state statutes, customs, business policy and the constitutions and rules of the organized exchanges. The New York stock exchange does not permit a corporation to become a member, consequently brokerage houses with memberships on the exchange are partnerships.

The distinction between brokers and jobbers, which obtains in London, does not exist in the United States On the New York stock exchange all brokers are free to trade with one another and with the public as they choose provided they conform with the constitution and rules of the exchange. Brokers on the New York stock exchange may be divided, according to the special nature of their business, into five groups (1) commission brokers, those who act for the public at a commission fixed by the exchange; (2) "two-dollar" brokers, who act as agents for other member brokers on the exchange at a rate of \$2 50 per 100 shares (the old name still prevailing although the \$2 rate has been superseded); (3) floor or room traders, those who buy and sell for themselves and for their own profit; (4) specialists, who specialize in certain securities and may act as commission brokers or floor traders but who ordinarily do not come into contact with the public, and (5) the odd-lot dealers, who supply or buy from commission brokers a sufficient number of odd lots to equal the full 100 shares, which is the minimum amount that may be purchased or sold on the exchange. While very few houses deal in odd lots. they usually have several representatives on the exchange and probably one-fourth of all the business done on the exchange originates in odd lots. The odd-lot dealer enables the small investor to trade in a few stocks or shares within a small fraction above the price at which large lots are bought and sold.

to price at which large iots are brough, and solu.

Brokers who are members of the New York stock exchange are controlled rigidly by the constitution, rules and customs of the exchange in an effort to secure fair competition and the proper relationship between the broker and his customer. For example, a broker may not take the side of the market opposite his customer, his charges are regulated, he must report accurately the

status of his business to the exchange, he may not advertise securities fabely and the advertising by the firm of itself is regulated explicitly by the schange. American stock exchanges are modelled after the New York exchange. Brokets are also regulated by the laws of their respective states and by the Securities and Exchange Commission created by federal law.

STOCKER, HELENE (1869-1943), German writer, editor, educator and organizer in the pacifist movement, was born at Elberfeld in 1869 Of a strict Calvinistic family opposed to higher education for women, she eventually went to Berlin in 1892, and was one of the first women to study philosophy, economics, art and literature at the universities of Berlin, Glasgow and Berne. She received a Ph D degree from the last named institution in 1901, subsequently settling in Beilin as an adult educator 1905 she founded the League for the Protection of Motherhood and Sexual Reform, and edited its publication, New Generation To her intransigence respecting more wholesome sex relations was added her firm pacifism, induced by Bertha von Suttner's story, "Die Waffen nieder" For cuticizing the treaty of Brest-Litovsk she was forbidden by the military authorities, for the remainder of World War I, to make further public pronouncements After the war she continued her work for peace as a member of the board of the Deutsche Friedensgesellschaft and in 1921 as a member of the International Peace bureau of Geneva Some of her proposals, notably one concerning a legal status for the children of unmar-11ed mothers, were incorporated in the constitution of the Weimar republic.

In 1922 she expressed her views on love in a novel entitled Labbe, and several collections of her essays appeared in the following years. With Hitlet's rise to power she was obliged to fee Germany, going first to Caechoslovakia, then to Switzerland, England, Sweden and eventually to the United States. She was deprived of her citizenship and her property by the nazi government. She dided in New York city, Feb 24, 1943

STOCK EXCHANGE or Bourse, a market for the purchase and sale of securities, such as shares, stocks and bonds Markets for dealing in securities have existed for centuries. They had their beignings usually in the regular meetings, in a certain place, a coffeebouse or restairant, of a few men who for a commission were prepared to act as intermediaries between buyers and sellers. As their business grew, these men formed themselves into a sort of a sociation, and rules were framed to regulate the conduct of their business. With the growth and wider distribution of wealth the volume of stock exchange business has steadily expanded, and during the ooth century the growth has been more rapid than in any similar period.

The development of joint-stock enterprise could never have reached its present stage but for the facilities which the stock exchanges provide for dealing in securities. Their primary function is to liquely capital by enabling a person who has invested money in, say, a factory or a railway, to convert it into cash by disposing of his share in the enterprise to someone else. Without the stock exchange, capital would become immobilised, for once invested there would be no means of liquelymp it.

London.-London was once the greatest of the world's stock exchanges in the range and volume of its transactions; and even after New York's rise to rival importance in the 20th century the range of London's business covered every corner of the earth and every class and type of security. It was not until the latter part of the 18th century that the London stockbrokers definitely formed themselves into a stock exchange with premises of their own, They had been in the habit of meeting and doing business in the Royal exchange and neighbouring places, but in 1773 those who had hitherto met at Jonathan's (coffeehouse), in Change alley, moved to a room in Sweeting's alley to which the name of the stock exchange was formally given, the building becoming known as the Stock Exchange Coffee house or tavern. Business grew anace, and in 1801 a group of members raised \$20,000 of capital in 400 shares of £50 each for the purpose of providing an adequate building and acquired a site in Capel court, Bartholomew lane, which today is one of the entrances to the "house."

The new building of the members was opened in 1802. At that

time the members of the stock exchange numbered about 500 Rules were drawn up for the conduct of business and for regulating membership of the house It was provided that all future members should be admitted by ballot, and members were required to pay a subscription of ten guineas each for themselves and five guineas for their clerks. It was the general intention that the shares should be held by members, but there were always a large number of members who did not hold shares The first extension was made in 1823 when the floor space was nearly doubled by the addition of a second room for dealings in foreign stock. In 1854. the two rooms with some small additions were rebuilt as one in the form of a dome with two transepts Several subsequent extensions of this building were made, the principal one being in 1885 when another dome was added Then in 1953 a public gallery was constructed to help dispel some of the ignorance about the true functions of the house The stock exchange building occupies the greater portion of the triangular area formed by Throgmorton street. Bartholomew lane and Old Broad street

Organization .-- Until the end of World War II the property of the stock exchange was under the control and administration of nine trustees and managers, who were appointed by the shareholders Business transactions on the stock exchange, however, were regulated not by these trustees and managers but by the committee for general purposes, numbering 30 members elected annually by their fellow members, which was charged with the admission of members and their clerks and was generally responsible for their good order and government but had no funds of its own and could not initiate or control the expenditure of the money subscribed by the members Though this system, known as dual control, worked remarkably smoothly, it was anomalous, and various efforts were made from time to time to terminate it. But none of these efforts succeeded until World War II when a complete change took place in the management of the stock exchange. In June 1945 the two controlling bodies were amalgamated into one entity known as the council of the stock exchange. The necessary revision to the rules and regulations of the stock exchange authorizing this change laid down that the council should at first consist of: (1) foundation members, who were to be the persons acting as trustees and managers at the time of the amalgamation; and (2) ordinary members, who were to be members appointed by ballot of the members of the stock exchange generally. It was, however, provided that after June 24, 1954, there would no longer be any foundation members, all such members being compelled to retire by that date, so that after 1954 all members of the council (from 30 to 36 in number) were to be elected by stock exchange members generally.

With the adoption of a revised constitution and the abolition of dual control, the stock exchange stopped distributing profits to the proprietors. But in order that members might retain their stakes 'n the equity of the stock exchange the 20,000 shares in issue were written down from £5 to 1x. shares. The council on March 1, 1948, issued 4,0000 64 redeemable annuities as compensation for the reduction of capital and for the surrender of rights to dividends. These annuities are redeemable by purchase at any time and any price, or by drawings after March 1, 1958, at 2500 for each annuity; and they may be reissued at any of a share qualification for membership was abolished. It was, of a share qualification for membership was abolished. It was hovever, provided that each member should hold at least one share for voting purposes, which could be obtained on application to the council.

The discipline of the stock exchange is very strict, and the council deals severely with members guilty of improper conduct. It has power to suspend or expel a member. The council also settles disputes between members and between members and their clients.

Securities cannot be dealt in on the stock exchange except by permission of the council, and conditions have to be fulfilled before that permission is granted. Before World War I any security could be dealt in without the permission of the committee, and all that the latter was called upon to do was to fix a special settlement for the completion of the first transactions. Sometimes

weeks would elapse before a special settlement was applied for and granted, sometimes none was applied for or granted Grave abuses occasionally arose in connection with the marketing of new shares in this way. The abolition of this licence to deal gave the interests of the public much better protection than they had previously enjoined.

Membership.—The income of the stock exchange (for the year to March 4a, 1953, it amounted to £506,63) is derived from the annual subscriptions of members and their clerks and from entrance fees paid by new members and from rents and investments. The fees have been raised from time to time. Members admitted with three surreties after March 24, 1876, but before March 25, 1879, paid an annual subscription of only 30 guiness. In the 1950s the annual subscription was 100 guiness for a new member with three surreties, 50 guiness for a new member with three surreties, 50 guiness for a member with three surreties, 50 guiness for undustricted clerks. By this time, too, the entrance fees were: 1,000 guiness for a member with three sureties, 500 guiness for a member with two sureties, 500 guiness for member with two sureties, 500 guiness for member with two

Before 1904 it was possible to become a member of the stock exchange without the nomination of a retiring member, consequently, membership increased rapidly in periods of activity, so that in periods of mactivity competition for business became extremely keen In 1904, however, it was decided to restrict the membership. Since then, in the ordinary way the only method by which a person may become a member is to obtain a nomination (by purchase) from an existing member who must retire in his favour. Nominations may be obtained from a former member, or, if he has not disposed of his nomination, from the legal personal representative of a deceased member Nominations, which are personal and nontransferable, are usually purchased, and the cost may range between £40 and £2,000. A candidate for membership must be recommended by three members, who become sureties for him during the first four years in £500 each, or £1,500 altogether. A certain number of clerks who have completed four years' service are admitted each year without nomination; for these, only two sureties of £300 each are needed, their liability extending for four years. Membership is for 12 months only, so that everyone who wishes to remain a member must apply to the committee for re-election.

In 1953 there were 3,577 members of the stock exchange, employing 1,445 clerks (of whom 847 had the right of entry to the floor of the house).

Business -By custom, each market has a special place allotted to it; for instance, the space immediately in front of the World War memorial is the market for British government securities and other gilt-edged stocks Dealers or jobbers in these securities take up their posts in this space every day, and dealers in other classes of securities similarly occupy the floor space allotted to their particular markets In this way the locality of a market can be readily and easily found by the brokers who go to the house to buy or sell securities for their clients. There is an important distinction between brokers and dealers. Brokers are not allowed to deal on their own account, nor can dealers act as brokers-this is the vital difference (see also Stockbroker). The dealer or jobber occupies a position similar to that of the wholesale dealer in commodities. He keeps a stock of particular securities, say oil shares, and his function is to buy oil shares when they are offered to him and to sell them if they are wanted. He quotes two prices for a share, his buying price, which is the lower, and his selling price, which is the higher, and the difference represents his profit. A broker acts for the public which desires to buy or sell securities. Ordinarily, both for buying and selling securities, though under certain circumstances only for buying, a commission is charged by the broker (the minimum for such commissions was fixed first before World War I but raised in 1952) On receiving an order to deal in a certain security, a broker goes to a jobber in that market and asks for a price, mentioning the amount of stock which he desires to deal in, but he does not disclose whether he is a buyer or a seller. The jobber "makes a price": i.e., gives two prices. At one he is

prepared to buy and at the other to sell. If the broker is satisfied with the price, or if it conforms with the price lumif fixed by he client, he will tell the jobber that he sells or buys, as the case may be, at the price quoted. On the other hand, if he is disastisfied, the broker will ask for a closer price, and if the jobber is anxious to do busness he will make a closer price and the bargain is then made. A jobber's busness tequires special qualifications. If has been said that a jobber is born, not made. There is much truth been said that a jobber is born, not made. There is much truth closer in the price of the price is the price of the price of the price is the price is the price of the price of the price is the price of the price of the price of the price is the price of the pr

When a broker has bought or sold shares he enters on a printed sing the name of the shares and the price at which the business was fone, he then agas the slip and drops it into one of the boxes provided for the purpose made the house. These slips are all collected, and the prices are printed that evening in the official list. This is what is known as the marking of bargains. A broker is not now compelled by the rules to mark each bragam, although he will usually do so in order that his client may read the price at which he defall in the official list or in the financial prices.

Except in the gilt-edged market, every bargain that a broker executes for his client is "for the account," unless otherwise speci-This means that the bargain will be completed (i e, the stock led over and paid for) on the next settling day. The usual handed over and paid for) on the next settling day, period of the account is a fortnight, but there are four 21-day accounts in the course of a year Settling days are usually fixed for a Tuesday, the passing of tickets-ticket day-takes place on a Thursday, and making-up day is Wednesday, prices for the settlement of current securities being fixed in the morning. Brokers on executing an order for a client send to him a contract note which sets forth the details of the transaction, the price obtained or to be paid, the amount of brokers' commission, of stamp and transfer fee and the amount of the contract stamp. Later, as settlement day approaches, a further note is sent to a client who has bought stock, requesting him to forward the purchase money. In the case of a speculative transaction the same procedure is adopted, except that the client, if he has bought stock, is required not to pay the total purchase money but merely the difference between the price which he gave and the price fixed on making-up day if the latter is lower than the former. If, however, the security has risen in price, the client receives a cheque for the difference between the price at which he bought and the making-up price

A rate of interest, or contango (q v), as charged for the facilities of buying and holding stock without paying for it. Contangose vary in accordance with the current rate of interest. Usually they are higher on the more speculative securities than on the investment type. The rate of a contango is also affected by the state of the "open" account, as it is called, in a particular share. If there is a large bull account, t, a, b, a large number of speculative purchases for a rise (see Butt.), and dealers are annous to discourage further buying, the contango may rise to 10% or more. Rates are generally lower on the more active shares and higher on the less active, which means that there are fewer people ready to carry the latter type of share.

Shares in which the market is narrow and difficult cannot be contanged. Some speculators self for a fall (see Bear) as well as but for a rise. Facilities for technically lending shares to speculators who have sold them are also provided, and the rate of interest charged for lending stock is called backwardation ( $\sigma$ 0.). This varies with the size of the hear account. If the buil account open in a stock is larger than the bear, there will be a contango rate and no backwardation rate, and twice versa.

Since World War I the facilities for carrying over bargains from account to account have been greatly reduced, but speculation has not disappeared. The speculators have merely changed their methods. The banks, instead of lending money to members of the stock exchange as largely as formetry for releanding to their clients, now lend freely to their own customers on stock exchange collateral, provided however that they believe the loan to be for a boan fide business transaction and not for purposes of secularity.

tion This is a safer method, for a bank rarely allows its client to borrow more than he can repsy Another popular device of speculators is to gamble during one account only If mailets are rising, a speculation will buy at the beginning of an account and self toward the end and vice versus Speculation is cheaper in this form, for by completing his operation in one account, the operator pays only one commission

The hours of business on the stock exchange are nominally from 9,30 AM to 3:30 PM, after which time the streets around the house are crowded with brokers and jobbers returning to their offices. Since World War I no sessions have been held on Satur-

days

New York.—The New York Stock exchange is the principal organized securities market of the United States It came into existence in 1792 and closely parallels, in its history, almost the source course of the life of the country.

entire course of the life of that country
It was in the third year of George Washington's first administration that a few businessmen who traded in the securities of
the day decided to appoint a place and a regular time for their
meetings New York city was then a small city by later standards It had 4,0000 people and occupied 5,000.

Congress, which first met in 1789, had authorized an issue of \$80,000,000 in bonds to refund the Revolutionary War debt. Banks and insurance companies were springing up in a number of places and public improvements were being started.

To pay for the cost of the Revolutionary War and to finance these other activities, stocks and bonds had to be sold to the public But the people, then as now, were unwilling to invest in securities unless they could be easily resold. The need for a market place for securities was clearly apparent

When these pioneer brokers decided to meet every day under the wide branches of an old buttonwood tree—it was located only a few blocks away, on Wall street, from the site of the present New York Stock exchange—they fullilled one of the most vital financial needs of a young republic. These men were the 24 original members of the New York Stock exchange. They dealt only ingovernment stock and a few issues of bank, insurance and canal company shares, and for their trading floor they had a small plot of ground protected by the branches of a tree.

The New York Stock exchange is a greatly broadened, highly mechanized and efficiently organized unit, world-wide in the scope of its services. But, in essentials, the market place experienced no fundamental change by going under a roof. It is an auction market where the securities of the largest and best-known business enterprises, representing the savings of the people, are continually appraised by a world consensus and where these securities may be readily converted into cash and cash exchanged for securities.

Many millions of people—possibly half the population of the United States—have a personal interest in securities markets, either directly as part owners of the companies and as holders of government and other listed securities, or indirectly, as the holders of insurance policies and savings banks accounts. Every bank and insurance company of consequence has a substantial proportion of its assets invested in listed securities.

As a market place, the trading floor of the New York Stock exchange affords exactly the same fundamental facilities that a public market does for the housewife or the auction room for the tobacco dealer. It is solely a convenience for the conduct of trade.

The exchange does not, as is supposed by some, buy or sell securities, not does it in any manner fix the prices of them. No part of the proceeds of a transaction goes to the exchange. Commissions, however, are charged by the brokers who act as agents for the public. The New York Stock exchange is an association of brokers. As members of the exchange, their principal function is to serve as a sents for people desiring to buy or sell securities.

When the exchange lists a security it requires that the issuing company be a substantial going concern; that it be legally organized and the securities validly authorized and issued; that there be sufficient distribution of the securities to assure a national market; and that the company comply with the exchange's requirements respecting adequate periodic reports of earnings, financial position and operations for the information of security holders and the public

Fundamentally, the rules of trading are those of auction markets. The highest hid has the floor, as has the lowest offer first bid or the first offer at a price has priority at that price. Each sale ends the auction and a new market is then started. All bids and offers are made orally, in an audible voice. Secret transactions are not pennitted, and the prompit publicity given to price by means of the stock and bond ticket tapes makes deception in respect to prices of bisted securities impossible the only function the exchange has with respect to prices is to publish them on the ticket tapes.

Legally, the exchange is a voluntary association, it has never obtained a charter or assumed the form of an incorporated body. Its membership is limited to 1,375, and anyone desting to become a member must purchase a membership for seat) from a returning member or from the estate of a deceased member. A candidate for membership must also be formally elected by the board of governors after a thorough investigation of his business career, his qualifications and general fitness to be a member. The candidate must agree, without qualification, as must general partners of members, to abide by the constitution and rules of the exchange, carrying as they do powers of sweeping character over all phases of his business.

The board of governors of the exchange consists of 25 persons, including a chairman of the board, a paid president, two representatives of the public and 2r others who are chosen from among the members of the exchange and from allied members (partners in member firms).

It is required that ten of the governors shall be members of the exchange, residing and having their principal places of business within the metropolitan area of the city of New York, four shall be alled members, residing and having their principal places of business within the metropolitan area of the city of New York, who shall be general or limited partners in member firms engaged in a business involving direct contact with the public; seven shall be members or albed members of the exchange, residing and having their principal places of business outside of New York, and not less than two of these seven out-of-town governors shall be members of the exchange. The chairman of the board is elected annually from among the members of the exchange.

The board of governors of the exchange is vested with all the powers necessary for the government of the exchange, the regulation of business conduct of members and allied members and the promotion of the welfare, objects and purposes of the exchange and, in the exercise of such powers, may adopt such rules, sues such orders and directions and make such decisions as it may deem appropriate (E Low).

American, Stock Exchange.—Known until Jan 5, 1953, as the New York, Curb exchange, the American Stock exchange as a voluntary unincorporated association of regular member stock brokers. As the second largest stock exchange in the United States, it provides a free and open auction market for securities of companies engaged in every phase of industrial, commercial, utility and rafficod endeavour. (For its earlier history, see Curp Mar-EST.)

Paris.—The origin of the Paris Bourse (bourse des volence), has been traced back to the money-changers' market of the year 1138. The perpetual rente (a bond usued by the state or by a least governmental body) was first introduced in France early in the 16th century. Transactions in securities were first conducted on the Bourse at the beginning of the 18th century. There were about 1s (mainly governmental) transferable securities listed on the Bourse in 1756; the 1866 the list comprised about 36 issues.

The Bourse is open from 12.30 to 2 30 P m., except on Sundays, Saturdays and legal holidays. There are three types of market, the official market or parquet, the curb market or marché des courtiers; and the free market or marché hors-cote.

The Parquet.—The rules governing the conduct of business on the official market were firmly established by the early part of the 19th century. According to these, the official stockbroker or agent de change has a transferable monopoly (now subject to governmental sanction), must act only as an agent and must not recommend the purchase or sale of securities to his clients Members of the stockbrokers' association or Compagnie des Agents de Change (whose number was limited to 70 in 1890) enjoy great social prestige. Their appointment, or charge d'agent de change, for which they post a bond or cautionnement, is granted by the president of the republic and can be passed from father to son or, under certain regulations, sold They are sworn government officials, subject to close governmental supervision (the government, for example, reserves the right to determine the rate of commission charged by them to their clients), and, under the system of solidarité (legally instituted in 1890), they guarantee both the accounts that they accept from their clients and from lenders of money and the integrity of officially listed securities Their association publishes the daily bulletin showing official quotations for listed securities, which comprise the leading French and foreign governmental and corporate issues, in all about 2,500 stocks and bonds (including about 250 foreign) The administrative body of the association is the chambre syndicale, elected annually by the members

Methods of trading on the official market are, in the first instance, divided into cash (au comptant) transactions and transactions for the term or for future delivery and settlement (à Cash transactions are made in any officially listed security for any amount thereof Orders are commonly placed either at a fixed price (à cours fixe) or at the best market price (au mseux) or at the average price (au cours moyen) On the parquet there is one settlement day a month, at the month's end, for future or à terme contracts Included in the list of securities available for term trading are the French state rentes, securities issued by important French banks, utilities and industries, and some foreign governmental and industrial issues. Because of the breadth and better prices which often prevail in the term market, it is used by both investors and speculators. Clients trading in the term market are permitted to engage in firm of nonoption (à ferme) or in option (à prime) transactions Finally, at the end of the month, all open accounts—of chents with their agents, of agents with agents or with lenders of money (reporteurs)-are settled through the central hquidation service (hquidation centrale).

The Corb and Free Monkets—The courters, in pursuance of the law of Feb. 16, 1942, have taken the place of the former basquiers or valeurs or coulistants. They too have a transferable monopoly. Whereas that of the agents de change covers all securities quoted on the official market, theirs covers securities not the free market are handled by them. The courter, however, is not a government official but only a commission agent, being appointed by the chambre syndicale of the agents de chonge after agreement with the chambre des courters; nevertheless he is required to post a bond and to show that he has capital assets not less than a faxed minimum. In 1953 there were about 50 courters.

The free market, then, comprises all shares quoted nether on the parquet nor on the marché das courtaers. When a new the is introduced in the Bourse, it is generally quoted first of all on the free market. Upon the share's steadying its quotation, the Association des Courtiers adds it to its list of securities Eventually, when they deem that the market for its broad enough the agents de change annex it to their own list Securities may thus pass through three successive stages, from market to market. Often, however, the middle stage, in the marché des contiers, is omitted.

(G V.)

Amsterdam.—The first exchange in Amsterdam was founded in 1611. Transactions were largely concerned with commodities but also with stock of the Dutch East India company and were of a very speculative character, comprising forward bargains, purchases on margin, option and put-and-call transactions. Already in the first half of the 17th century a daily list was sused, containing, however, exclusively rates of exchange The Confusion de confusiones of Joseph de la Vega, a Spanish Jew, shows that speculation was the prevailing feature of those days.

In 1787 the Association for Trading in Bonds was founded, with its own clubhouse, henceforth stockjobbing was separated

from the trade in commodities In 1845 a new exchange, in which stockpobbing also took place, was built at the Dam In 1876 the Veieninging voor den Effectenhandel (Stock Exchange union), a private association, began to regulate the stock exchange Rules had already been evolved to protect both the public and members.

The exchange built by H P Berlage for the Amsterdam municipality at the Damaka in 1903 allotted about one-quaster of tapatry at the Damaka in 1903 allotted about one-quaster of the space to the stock exchange, but this soon proved to be too little The Stock Exchange union therefore had a new exchange of work built by J Cuypers, which came into use in 1913 and is connected with the Berlage exchange by an overhead passage

Before World War I, prehaps because of the Netherland's meccantile and seafaring tadition, pelhaps because modstry was underdeveloped at home, the Dutch investor showed a strong micination for foreign securities, patientially for US ones. After World War I capital surpluses were more and more directed to the East Indies, and there was a boom on the Amsterdam exchange until 1929, when the world economic depression began During their occupation of the Netherlands in World War II the Germans tred to disrupt business on the stock exchange as much as they could, that we prompts. After the liberation in May 1925 these amovations were somewhat mitigated but it was not until 1953 that the old articles were re-established.

The Stock Exchange union, though remaining a private association, was in 1914 subordinated to the minister of finance insofar as the latter was given the right to regulate the exchange's opening and closing and to approve the listing of new securities

The Amsterdam exchange, which in more prosperous days had had 800 members, had 500 m 1954. Transactions in a security in which no constant dealing takes place are handled by a hockman, that is, by a jobber specializing in that security and receiving a small commission from the brokers who pass orders to him. Every broker, however, has a right to bid or offer in any security listed, if circumstances would give rise to open trading. Official dealings start at 1 15 PM and terminate at 2 OP M

Since the end of the 10th century the Amsterdam banks have been members of the stock exchange, so that many transactions are effectuated not on the stock exchange itself but in the banks; such internal clearings, however, are based on the official quotations and governed by the regulations. The stock exchange has fixed minimum commission traffs, but no broker would charge a

higher commission than those minimum rates.

To speak generally, there is no forward market for stocks in Amsterdam, most dealings are for money", settlement usually takes place on the same day as the conclusion of the bargain, dolivery four days later Opton dealing is, however, possible. Upto World War II, a considerable number of transactions were done on "prolongation" (purchase on margin), whereby the security was pawned and the purchaser paid a surplus of 26%, at least on the market value, such loans could be "prolonged" at the prolongation. After World Wai II, however, all purchases have to be fully paid in cash. Bear transactions are likewise prohibited, though in practice a bear seller may borrow or line the securities that he has to deliver

Basic, Geneva and Zurich.—There are stock exchanges in a number of commercial centres in Switzerland, namely Basic, Berne, Chur (canton of Grisons), Geneva, Lausanne, Lucerna, Neuchkel, St. Gall and Zurich Of these, those situated in Basic, Geneva and Zurich are most important, and from the legal point of view it is in these cantons only that the markets come under the supervision of the cuntonal authorities In the other centres, the markets rank as private organizations. While the principal government and industrial securities are quoted in all the stock exchanges, the smaller centres generally come into use in connection with dealings in securities of a strictly local character (e.g., hotels, local or mountain railways) in which they, often specialize by writte of their geographical situation.

The stock exchange of Basle, originally founded in 1875, now functions under a cantonal law of Feb. 17, 1944; that of Zunch, originally founded in 1876, functions under one of 1883 subse-

quently modified on Dec 22, 1912, and subsequent additional legislation, that of Geneva, however, founded by the Société des Agents de Change in 1850, received legal status under a cantonal law as

early as Dec 20, 1856

While the exchanges are thus strictly individual in their organization and vary from place to place, the Vereingung Schweizerischer Effektenbersen endeavours to secure the maximum possible uniformity. This such matters as the formalities of admixion of foreign securities on the Swiss stock exchanges are regulated by this body. The admitted members each stock exchange form a committee or managing body which is responsible for the general control of the market,  $\sigma_s$ , membership, the financial sittus of members, the accounting and the presentation of accounts, the settlement of disputes and usances. It is these usances which in turn determine the manner of delange;  $t\sigma_s$ , the procedure required in the case of transactions for cash or for forward dates, delivery of stock, exercise of rights, etc.

In the three principal markets, of which Zurich, with a monthly record in 1933 of about 6,35 markings (of Geneva's 3,000 and Basle's 2,100), is the most important, only firms which have the approval of the cantenial authorities and are members of the Boersenkammer or the Effekten Boersenwerein can transact bussenses (the turnover of business in Zurich in 1932 was 6,137,1000,000 Fr. as against 1,792,000,000 Fr. in the case of Basle, Geneva did not publish corresponding figures). In Geneva the transaction of business was fournerly restricted to the agents de change, through whom all transactions had to be effected, but after 1934 consisted of three members representing the private or commercial banks, three members representing the frederal bankings organizations and two members representing the frederal bankings.

Dealing on the stock exchanges of Basie, Geneva and Zurich is restricted to banks authorized by the professional association of

dealers for the exchange in question

Only securities officially introduced can be dealt in on the stock exchange. The dealings which regularly and extensively the place in nonquoted securities (including newly issued stocks not yet officially introduced and foreign securities of all kinds) take locaentirely outside the stock exchange and are not officially marked on any record. Banks work on a commission basis and in the case operate technically as responsible principals in their own names even though they may represent third patters

Business is transacted daily in the ring or corbaile, access to which is exclusively reserved to authorized dealers. When the session opens, the clerk of the stock exchange reads out the names of the securities quoted in the order of the official price list Bonds are read out and dealt in in the first part of the session, shares in the second Once each security has been read out, dealings therein may begin between members in the ring by direct verbal negotiation (no jobbers or their equivalents are employed) and may continue so long as the session remains open In Zurich there are two rings, one for bonds and the other for shares. At the close of business, the list is read through again and dealers and ignresentatives of the Boersenkammer or association take note of all puces recorded during the session, any necessary corrections or adjustments being made. The list, which is then officially published, comprises all transactions officially recorded, markings being in each case qualified by an indication showing whether the deal is for cash, for end of the current (settlement) month or the end of the following (settlement) month (A. H. SH )

Milan.—The most important Italian stock exchange is that of Milan, which was founded in 1808. It is membrahip in 1933 comprised 104 agenti di cambio (about one-third of the total number of such agenti in Italy), who dealt in about 330 securities coof it them shares, 107 mortgage and other bonds and 23 government securities); and transactions on it constituted 60% of the total

number of such transactions in Italy in 1952.

The rules governing Italian stock exchanges are fixed by law. Stock exchanges, established by decree of the president of the republic, are administered by the local chambers of commerce and supervised by the treasury, by the deputation did borso (nominated verty year by the treasury to watch the trends of buistiness) and

by the directing committees of the agents di cambio (elected every two years by the general assembly to see that agents do not overstep the limits of their competence, to act as friendly arbitrators or in disputes efferred to them and to compile and publish the official lists); a representative of the treasury, moreover, attends the election and the subsequent sessions of the committee.

An agente di cambo is a public official appointed by presidential decree as the result of a competition, he is not allowed to deal on his own behalf or to hold interests in firms whose normal business is predominantly concerned with stock exchange transactions. His rate of commission is fixed by the treasury. Direct negotiations by word of mouth can be conducted only by these agents or their representatives, the leading banks, however, may have their observers in the stock exchanges, and persons whose normal business is concerned with the stock exchange are admitted on presentation of a succession hass.

Hours of business are the same for all Italian stock exchanges, being fixed by the treasury as from 10 15 AM to 12 45 PM every day except on Saturdays, on holidays and two weeks during the month of August.

The Italian stock exchanges deal in national, communal and provincual securities, in mortgage and other private bonds and in shares Methods of trading include transactions a content (for eash), which are of little importance, being almost entirely confined to securities of fixed value; transactions a termine (for the term) which constitute the greater part of stock exchange business, being concerned with shares, and transactions a premio of which option dealing alone is fairly widespread Shares, consolidated and redeemable government stock and a few other securities are quoted at tel qual rates, securities of fixed value usually at a price exclusive of accrued interest. Settlement takes place at the end of the month, through clearing houses. (LA R.)

STOCKHOLM, the capital of Sweden, on the east coast, not far south of the junction of the Baltic sea and the Gulf of Bothnia The population of Stockholm in 1751 was 61,040, in 1850, 93,070; in 1850, 176,875; in 1900, 300,624, in 1950, 824,850.

Origin.-Before Stockholm arose, Bjorko, Sigtuna and Uppsala were places of great importance. Bjorko ("the isle of birches"), by foreign authors called Birka, was a kind of capital where the king lived occasionally at least; history speaks of its relations with Dorestad in the Netherlands, and the extensive refuse heaps of the old city, as well as the numerous sepulchral monuments, show that the population must have been large. But though situated at a central point on Lake Malar, it was destroyed, apparently before the beginning of the 11th century (exactly when or by whom is uncertain); and it never recovered. Sigtuna. lying on the shore of a far-reaching northern arm of Lake Malar. also a royal residence and the seat of the first mint in Sweden, where English workmen were employed by King Olaf at the beginning of the 11th century, was destroyed in the 12th century. Stockholm was founded by Birger Jarl, it is said, in or about 1255, at a time when pirate fleets were less common than they had been, and the government was anxious to establish commercial relations with the towns which were now beginning to flourish on the southern coast of the Baltic. The city was originally founded as a fortress on the island of Stadholm. The castle was erected at the northeastern corner, and the city was surrounded with walls having fortified towers on the north and south It came to be called Stockholm ("the isle of the log," Latin Holmia, German Holm); the true explanation of the name is not known. During the middle ages the city developed steadily, and grew to command all the foreign commerce of the midlands and north, but it was not until modern times that Stockholm became the capital of Sweden. The mediaeval kings visited year by year different parts of the kingdom.

Situation.—Stockholm is famed for the beauty and physical

Situation.—Stockholm is famed for the beauty and physical characteristics of its situation. The coast is here thickly fringed with islands (the skörgörd), through which a main channel, the Saltsjö, penetarise from the open sea, which is nearly 40 mi. from the mainland. A short stream, with a fall normally so slight as to be sometimes reversed by the tide, drains the great lake, Millai into the Saltsjö. The city stands at the junction of the lake and the sea, occupying both shores and the small islands intervening. From the presence of these islands a fanciful appellation for this city is derived—"the Venice of the North", but actually only a small part is insular. There are five main divisions, Gamla Staden, old town, ancient nucleus of the city, properly confined to Stadholmen (the city island) which divides the stream from Malar into two arms, Norrstrom and Soderstrom, Norriman on the north shore of the channel, including the business section; of Starmann, eastern residential section, Kungsholmen, to the wei, manufacturing and municipal centre, and Sodermalm, to the south, manufacturing are

Gamla Staden.—Ancient origins are apparent in the narrow, winding streets, though the individual holess are not very old, owing to the rawages of frequent fires. A few, however, preserve antique narrow fronts with gables, as in some of the North German towns. The old market, still called Stortong (great market) is now one of the smallest in Stockholm. At the north angle of the island is the royal palace (Stott). The original building was destroyed by five in 1697, the body of Charles XI being with difficulty rescued from the flames. A new palace after designs of Nicodemus Tessin the younger (d 1728) was not completed, owing to wars and the general distress, until 1754, while a restration carried out in 1901 included many ornamental details devised by the architect and executed at the expense of King Occar III. The new town hall designed by 5 bisters combines Swedish traditional styles with Italian influences, it is one of the world's more magnificent buildings.

West of the palace are the offices of the majority of the ministries, some of them in the former buildings of the royal mint.

BY COUNTER OF SWEDISH STATE BALLWAYS
THE ENGELBREKTSKYRKAN, NORRMALM, A CHURCH NAMED AFTER
ENGELBREKT, SWEDISH PATRIOT,
WHO WAS ASSASSINATED IN 1436

Beyond these, on the west side of the island, is a square named from the palace on its northern side. the Riddarhustorg Riddarhus (house of the nobility) was the meeting place of the Council of the Nobles until 1866. and its hall is adorned with the armorial bearings of noble families. The north forecourt has a statue (1800) of Axel Oxenstierna, the chancellor, by J. Borjeson In Riddarhustorg is a statue of Gustavus Vasa, unveiled in 1773 on the 250th anniversary of his accession. Southwest of the royal palace is the Storkyrka (great church), dedicated to St Nicholas, the oldest church of Stockholm, greatly altered from its original state. The date of its foundation is 1264; but it was

practically rebuilt in 1726—43. Within it is richly adomed with paintings and wood carving. Gamla Staden is the commercial centre of the city. At the broad shipping quay (Sheppstrow) which flanks the palace on the north and east, most of the seagoing steamers lie; and the exchange, customhouse, numerous banks and merchants' offices are in the immediate vicinity, Rid-darholmen (nobles' island), lying immediately west of Stadholmen, contains the old Franciscan church (Raddarholmskyrha), no longer used for regular service, which since the time of Gustavus Adolphus has been the burial place of the royal family. It has recently been restored, and contains mediaeval pantings, and many trophies of the European wars of Sweden. On one side of it stands the old house of parliament; on the other a statue of Birger Jarl, the reputed founder of the city. On Riddarholm also are varous government offices, and most of the steamers for Malar and the inland navigation lie alongside tis quays.

Normalm.—Staden is connected with Normalm by the Normalm of the Holy Spirit), on which are situated the new houses of parlament and the Bank of Sweden. A third bridge connects with the main thoroughfare of Normalm, Drottningstann (Queen street). The Norrbor gives upon Gustaf-Adolisation (Control of the Norrbor gives upo

Torg, where a statue of that king stands between the royal thearter, royal opera house and the palace of the crown prince Normalm is the finest quarter of the city, with broad straight streets, several open spaces with gardens, and handsome buildings. East and north of the theater royal, the Karl-den-Tolites-Torg and Kungstradgård (royal garden) form the most favoured winter promenade. There are a statue of Charles XIII and a fountain with allegorical figures, by J P Molin, also a statue of Charles XIII, and in the small Berzeili park close at hand one of the chemist J. J. Berzelius Near Drottningsgatan is the Klara church, the burlial place of the poet K. M Bellman, and west of this, occupying one side of a square, is the central railway station. In the building of the academy of scence is the national museum of natural history, including mineralogical, zoological and ethnographical departments

Other Districts.-On the island of Kungsholm, S. of Vasastad, are the Caroline medical institute, several hospitals, including the Serafimer (1752), the royal mint and factories, Ostermalm, lying east, that is, on the seaward side, of Norrmalm, is a good residential quarter, containing no public buildings of note, save the barracks of the Swedish guards and the fine royal library, which is entitled to receive a copy of every work printed in Sweden The library stands in the beautiful park of Humlegård (hopgarden), in which is also a statue of Linnaeus South of Ostermalm, and east of the Kungstradgård and Staden, hes the peninsula of Blasieholm (formerly an island) and, connected by bridges, the islands of Skeppsholm and Kastellholm, the three forming the foreground in the beautiful seaward view from the Norrbro. On the first is the national museum (1866), a Renaissance building, containing historical, numismatic and art-industrial collections, with ancient and modern sculptures, picture gallery and engravings. The numismatic collection is notable for its series of Anglo-Saxon coins. About 11,000 pieces came from the island of Gotland, some dating from 901-924, but the majority are later. In front of the museum is a bronze cast of the famous group of J. P Molin (1859), the "Baltespannare" (belt-bucklers), representing an early form of duel in Scandinavia, in which the combatants were bound together by their belts.

East of Skeppsholm an inlet, Ladugårdslandsviken, so named from the proximity of the former royal farm-yard (ladugard), and bordered on the mainland by a quay with handsome houses called Strandvagen, throws off a narrow branch (Djurgårdsbrunnsviken) and separates from the mainland an island about 2 mi. in length by 4 mi. broad. This is mainly occupied by Djurgården (the deer-park), a beautiful park containing the buildings of the northern museum, a collection of Scandinavian costumes and domestic and agricultural utensils, and a biological museum housed in a wooden building imitating the early Norwegian timber churches (stavekirke). Here also is Skansen, an ingenious reproduction in miniature of the salient physical features of Sweden with its flora, fauna and characteristic dwellings inhabited by peasants in the picturesque costumes of the various districts. Both the northern museum and Skansen were founded by Dr. Arthur Hazelius (1833-1901). There is a bust of the poet K. M. Bellman, whose festival is held on the 26th of July. Sodermalm, the southern quarter, is principally residential.

The heautiful environment of sea and lake is fully appreciated by the inhabitants. To the north of the city, accessible by rail and water, are the residential suburbs of Haga and Ulriksdal, with royal chateaus, and Dyursholm. Saltsjöbaden, poin least of Stockholm, on Baggensfjord, is the nearest and most favoured seaside resort, but Dalaró (ao mi. southeast) and Nynskamm (39 mi. south) are much frequented. Vaxholm, 12 ml. northeast by water, is a pleasant fishing village where numerous villas have been built.

Institutions.—Stockholm is the centre of government and the usual residence of the king; in summer he usually occupies one of the neighbouring country palaces. The city is the seat of the high court of instite (Högsta Domstolen) and of the court of appeal for the northern and midland districts (Svosa Hofyatt) As regards local government, Stockholm is a lim (administrative district) in itself, distinct from the rural lim of the same name, under a high governor (Evertathillarer) and deputy, with departments for secretarial work, taxation and police. The city is in the ducese of Uppsala, but has a separate consistory, composed of the rectors of the city parishes, the president of which is the rector of St Nicholas (Storkyrka). Stockholm has no state university. A private university (Hogskola) as founded in 1878, and

THE CITY HALL AT STOCKHOLM, COMPLETED IN 1922

was brought under state control in 1904. The president of the governing body is appointed by the government, while the appointment of the remaining members is shared by the Swedish cademy, the Academy of Sciences and the city council. The faculties are four—philosophy and history, philology, mathematics

and natural sciences and jurispudence. The Caroline institute (Krolinka Metho-Kuruguka natisia) is a medical foundation dating from 1815, which ranks after 1814, with the state universities of Upposals and Lund in the right to hold examinations and confer degrees in its special faculty. Special and secondary education is highly developed; there are schools of agriculture, mining and forestry, technical schools, a veternary school, a school of pharmacy, etc. Among the public schools under state conting, one, the Nya Elementarskolan, was founded experimentally in 1828, after the education committee of 1825—28, among the members of which were Tegnér and Berzelius, had reported on the want of such schools. This school retains its separate governing board; whereas others of the class are under a central board The control of the primary schools in the parishes is similarly centralized; whereas in Sweden generally each parish has its school board.

Stockholm is the seat of the principal learned societies and royal academies. (See Sumes»). There are schools of painting, sculpture and architecture under the direction of the Royal Academy of Arts; a conservatory of music under that of the Royal Academy of Musics, and experimental gardens and laboratones under the Royal Society of Agraculture. Outside the city is the Thiel gallery, with a rich collection of the works of Liljefons, Carl Larsson and Anders Zorn. The Natural History museum, the observatory and meteorological office, and the botanical gardens are under the supervision of the Royal Academy of Sciences.

Minor collections deserving mention are the museums of the geological survey and the Caroline Medical institute, and the archives in the record office (Riksarkivet).

Among places of entertalment, the royal theatre is managed by a company receiving a state subsidy. The Dramatic theatre (Dramatiska Teatern), in Kungsträdgårds-Gatan, the Swedish (Svenska) theatre in Blaischom-Gatan, and the Vasa theatre in Vasa-Gatan may also be mentioned. The Djurgård is the principalese for variety entertainments in summer. Several of the leading sporting clubs have their headquarters in Stockholm. An annal regata is sheld early in August by the Royal Swedish Vacht club (Svenska Segaluālskapet). A harbour much frequented by yachts is Sandhamn in the outer skargård.

The Stockholm General Skating club (Almänna Skridskoklubb) is the leading institution for the most favoured winter sport. A characteristic spectacle in winter is the tobogganing in the Humlegård on holidays.

The principal athletic ground is the Idrottspark (sports park), on the north side of Östermalm, with tennis courts and a cycing track, which may be changed into a skating-rink in winter. There is a similar park at Djursholm.

A stadium in Swedish mediaeval style, seating 15,000, was opened for the Olympic games in 1912.

Industry and Commerce.—Stockholm's industries are varied.

Industry and Commerce.—Stockholm's industries are varied, including iron and steel, engineering, shipbuilding, and the manufacture of a great number of consumption goods such as flour, beer, tobacco, clothing, leather, etc. The nearby Gustavsberg and Rofstrand potteries produce excellent wares. Government mining, printing, etc., is done here All told, Stockholm manufactures about three times in value the product of either Malmo or

Gothenburg. Stockholm is the first port of the country for imports, but in exports about equals Malmo and falls below Gothenburg, total tonnage is about 11,000,000 annually About 50% of the shipping tonnage is Swedish The channel is 32 ft. deep, and vessels of 23 ft. draught can tue up at Skenpsbro and Blassholm.

There is an outport at Vartan on Lulla Vartan channel to the northeast. The Hammarby channel takes vessels up to 3,500 kms. There is an intreate transportation centre in and over Slussen, connecting Lake Malar with the Baltic by water and also Gambard Staden with Sodermalm by land, All trains into the city have been electrical.

See P. R. Ferlin, Stockholm, Stad. (Stockholm, 1854-185); C. Lundin, and A. Strindlers, Gamla Stockholm (Stockholm, 1889); C. Lundin, Nya Stockholm. (Stockholm), 1860); G. Nordensvan, Malarrentinsgen-lifte gueen for Malari (Stockholm, 1860); E. W. Dahligen, Stockholm, 1860); E. W. Dahligen, Stockholm, 1867; issued by the muscapal council on the octasion of the Stockholm Exhibition, 1897).

STOCKINETTE. A term strictly denoting a particular variety of knitted or hoisery fabric composed of wool, cotton, silk or artificial silk, and produced as a tubular fabric and in a continuous pecce of indefinite length on a knitting machine of the circular type. The fabric may be used in its tubular form, or may be cut lengthwise and opened out into single width, to be made up into the numerous garments for clothing and other articles for domestic use.

STOCKJOBBER: See JOBBER (STOCK EXCHANGE). STOCKMAR, CHRISTIAN FRIEDRICH, BARON VON

(1787-1863), Anglo-Belgian statesman, who came of a Swedish family, was born at Coburg on Aug. 22, 1787. He was educated as a physician, and became attached in 1816 to Prince Leopold of Saxe-Coburg-Gotha on his marriage to Princess Charlotte of England When she died next year he remained Leopold's private secretary, controller of the household and political agent, until the prince became in 1831 king of the Belgians His disinterestedness and profound acquaintance with English and European social and political questions impressed themselves on all who were associated with him. In 1831 he retired to Coburg, in order not to excite Belgian jealousies by residing at court as confidential adviser, but he continued to be Leopold's right-hand man In 1837 Leopold sent him to England as adviser to the young Queen Victoria, and in the next year he accompanied Prince Albert (afterward Prince Consort) on his tour in Italy. He won the complete confidence of the prince as well as of the queen, and on their marriage in 1840 he became their trusted though unofficial counsellor, dividing his time between England and the continent. He died at Coburg on July 0, 1863.

See the articles on Victoria, Quiers; and Albert, Prince Consort of England. Selections from Stockmar's papers were published by his son Einest in 1872, and a biography by Juste appeared at Brussels in 1873; see also The Letters of Queen Victoria (1907).

STOCKPORT, a municipal, county and parliamentary borough of Lancashire (in part) and Cheshire (in part). England, 6 mi. S.E. of Manchester. Pop. (1951) 141,660. Area 12.5 sq mi. The boundaries of Manchester and Stockport meet in Levenshulme. The ancient town stood on the slopes of a narrow gorge where the Tame and Goyt join to form the Mersey, but the modern town has extended on to the more level land above. There are river bridges and a lofty railway viaduct bestrides the gorge. Stockport is served by the L.M.S. and L.N.E. railways. Motor buses connect it with Manchester. The town is an important industrial and railway centre. Its industries include cotton and felt hat manufactures, the construction of machinery for the cotton trade, motor and electrical engineering, bleaching and dyeing, and the manufacture of leather and of foodstuffs. The public buildings include the church of St. Mary (built about 1817) with portions of earlier date and a Decorated east window; St George's church (1897); St. Mark's church (1921); the town hall (1908), designed by Sir Brunwell Thomas; the central library (1913), the grammar school (1916) and the Hall of Memory. In all there are 415 ac. of parks and grounds. The Kinder waterworks (1912) have a reservoir covering 44 acres; the Goyt valley works were opened in 1937. The old Stockport grammar school was founded in 1487 and the Stockport Sunday school (founded 1784) is one

of the largest in the kingdom Stockport returns two members to parliament It was enfianchised in 1832, incorporated 1835, and became a county borough in 1888. Richard Cobden represented Stockport in parliament from 1841 to 1847.

During the Roman occupation there was a small military station on the site of Stockport, at the junction of two Roman loads. The etymology of the name may be Saxon, but there is no evdence of a Saxon settlement, and the place is not mentioned in Domesday. A castle was in existence in the 12th century, but is not mentioned after 1327. Stockport (Stokeporte, Stopport, Stopford) was made a free borough by a charter of Robert de Stokeport about 1220. This Stockport was not a true municipal borough until formally incorporated under the Municipal Corpolations act of 1835

STOCKS, a wooden structure formerly in use both on the continent of Europe and in Great Britain as a method of punishment for petty offenses. The culprit sat on a wooden bench with his ankles, and sometimes his wrists or even neck, thrust through holes in movable boards, generally for at least several hours. That stocks were used by the Anglo-Saxons is proved by their often figuring in drawings of the time (see Harleian mss. No 65). The second Statute of Labourers (1351) ordered the punishment for unruly artisans. It further enjoined that stocks (cennes) should be made in every town between the passing of the act and the following Pentecost. The act appears to have been ill observed, for m 1376 the commons prayed Edward III that stocks should be set up in every village. Though never expressly abolished, the punishment of the stocks began to die out in England during the early part of the 10th century, though there is a recorded case of its use so late as 1865 at Rugby. In many villages may still be seen well-preserved examples of stocks, in some cases with whipping posts attached. In the United States stocks were of frequent use in the 18th century, more particularly in the New England states; while in the southern states they were employed for punishing slaves (see Pillory),

STOCKTAKING. To prepare a balance sheet it is necessary for a trader to arrive at a valuation of his stock-in-trade; this process is called stocktaking or, in the U.S. inventory taking. When proper stock records are available, they are an invaluable check upon the accuracy of the stocktaking; but in their absence it is essential that the process of stocktaking should be performed with the utmost care. If a wrong value be placed upon stock, the accounts embodying that valuation will to a corresponding extent mis-state the profits of the undertaking and its current financial position, and to a corresponding extent the accounts of the ensuing period will be affected in the opposite direction. The lower the rate of turnover the more serious will be any error in the periodical stocktaking. In many cases, the only independent check that the trader has upon the accuracy of his stocktaking is the inherent probability of the percentage of profit shown by the trading account (See also Financial Statements.)

The generally accepted basis for the correct valuation of stockin-trade, assuming the goods to be in a readily saleable condition, is either the price they actually cost or the price at which they could then be bought in the open market, whichever of the two be the lower.

But although it is unsound to take into account any rise that there may have been in market values since the goods were bought, it would be equally unwise for a trader to dispose of his stock upon a rising market at normal pruces, where he can only replace the goods sold at a greatly enhanced figure. Usually, therefore, although rising market prices are gnored for stocktaking purposes, selling prices are advanced as buying pruces in crease; and this is equalized by the fact that as buying pruces fall, it commonly becomes necessary for the trader to reduce his selling prices, though he still has stock purchased at the higher rate.

Responsibility.—In most bisinesses it is usual to make the general manager responsible for the general accuracy of the stocktaking. The managers of departments are responsible to him, and the actual work is spit up among the various employees, each of whom is held responsible for his section of the work. Those employed in counting, measuring or weighing goods are usually those familiar with the handling of these goods, and thus able to identify them as being correctly described. The cost prices are then entered on the list by clerks from actual invoices. The managers decide what (if any) percentage is to be deducted from goods that are old-fashioned, or otherwise out of condition, and the remaining calculations are then completed in the office, after which the summary is certified by the general manager

The actual process of taking stock is often rendered more difficult and uncertain because it has to go on while trading operations are in full swing, and goods are accordingly constantly coming in and going out It is very necessary to take precautions to ensure that no errors arise from this cause. For this reason some bisiness houses prefer to close their premises during stocktaking, even though it means a corresponding loss of trade. Further, it is important to see that the invoices relating to all goods which have in fact been included in stock are also included in the books are presented to the control of the control of the control of the properties of the control of the control of the control of the actual between the control of the control of the control of the actual between the control of the control of the control of the actual between the control of the control of the control of the control of the actual of the control of the

When the trade is a seasonal one, it is usual to fix a date for stocktaking that comes between the two seasons, as it is naturally more convenient to take stock when the stock is at its lowest In such cases it sometimes happens that delivenes of new season's goods have already been accepted, the invoices for which are "dated forward," \*re\*, into the new accounting period. In such cases it seems admissible to exclude the value of these goods both from the purchases of the past period and also from the stocktaking.

(I. R. D.)

STOCKTON, CHARLES HERBERT (1845-1924), US naval officer, was born in Philadelphia, Pa , Oct. 13, 1845 He saw active service with the "Macedonian" during the Civil War, graduated from the United States Naval academy in 1865 and served on the "Swatara" on a voyage around the world, 1874-75. He commanded the "Thetis" from 1889 to 1891 and served on the Asiatic station as commander of the "Yorktown" from 1895 to 1807. He was president of the Naval War college from 1808 to 1000, and after commanding the battleship "Kentucky" from 1001 to 1903, he served as naval attaché in London until 1906. He was promoted to rear admiral in 1906 and became president of the naval examining and retiring boards and the board of inspection and survey. Following his retirement in 1907 he was first delegate to the London Naval conference 1908-09 and from 1910 to 1918 was president of George Washington university where he lectured on international law. Included among his various publications in the field of international law are International Law: Recent Subreme Court Decisions and Other Opinions and Precedents and Outlines of International Law (1914). Stockton died in Washington, D.C, on May 31, 1924.

STOCKTON, FRANCIS RICHARD (1844—1902), U.S. writer, was born m Philadelphia, P.A. April 5, 1844, Upon graduating from high school Stockton studied wood engraving, but soon turned to journalism. He contributed profilically to periodicals, and was variously on the staffs of Heerls and Home, Contray Magazine and St. Nicholas Magazine, of which he was assistant editor in 1873, From 1851 he devoted himself to authorship. He

died in Washington, D.C., April 20, 1902.

Illustrative of the seven categories of "romantie" narrative within which Stockton wrote are the fairy tales in Ting-a-Ling (1870), the conventional love story of Arias Clowerdon (1893), the outdoor romance of The Adventures of Caphain Horn (1893), the science faction of The Greet Stone of Seadies (1898), the sixtical tale in Kate Bonnet (1902), the high whimay of Rudder Grange (1879) and the enignatic fantasy of "The Lady or the Tiger?" (1882). Stockton's short stories are more successful than his novels; his Tame probably rests upon the last two titles.

G. C. K.)

STOCKTON, RICHARD (1730-1781), signer of the Delaration of Independence, was born Oct. 1, 1730, in Princeton, N. J. He was the grandson of another Richard Stockton, who was one of the original settlers of the city and the owner of the land which became the centre of modern Princeton. He was educated

at the College of New Jassey at Newark which later, largely though the efforts of his father, was moved to Prunceton and became Pranceton university. After his graduation in 1748, young Stockton studed law in Newark, and his admission to the barriers, 1875, was the beginning of a long and successful career as an attack. The state of the College of New Jersey and was able to persuade John Withershoon to accept the presidency of the college, a position the later had previously declined. From 1768–76 Stockton served on the executive council of his native colony and from 1774–76 as an associate justice of the New Jersey supreme court. In 1776 he became a member of the continental congress.

Stockton's attitude on the relation of the colonies to Great Bratian underwart, a considerable change in the years before the outbreak of the Revolutionary War The first record of his opinion is dated 1764, at which time he felt that any difficulties between the colonies and England could be settled by the inclusion in parliament of some US members Ten years later, however, his letter to Lord Dartmouth entitled An Expedient for the Seltement of the American Disputes advocated that the colonies be allowed to be completely self-governing and responsible only to the king By the time of his election to congress, he was convinced of the advisability of independence for the colonies, and he not only signed the Declaration of Independence but argued in

favour of it before its passage

He was re-elected to congress in 1776 and in the same year declined the position of chief justice of the New Jersey supreme court, to which he was elected unanimously, having previously been defeated for governor In Nov 1776, he was captured by the British at the home of a friend in Monmouth, N J., and imprisnced in New York city. Before his release, which was secured several months later by Washington himself, his health had suffered so hadly that he never recovered In addition, most of his fortune was gone, his lands and buildings having been looted by the British in his absence He did not return to public life, but spent the years until his death quietly in Princeton. He died in that city, Feb 28, 1787.

STOCKTON, ROBERT FIELD (1795-1866), US mand officer, was born in Princeton, N.J., Aug. 20, 1795, the grandson of Richard Stockton (9° v), siner of the Declaration of Independence. He attended Princeton college for a time, but in 1811 joined the navy as a midshipman, shortly becoming attached to the frigate "President," under the command of Commodere John Rodgers. He served under Rodgers during the War of 1812 except for a brief period in Washington as and to the secretary of the navy, and at the conclusion of hostifities was transferred to the Mediterranean, where he remained until 1821, parturpating (1815) in the war against the Barbary pirates. In 1821 he was placed in change of the schooner "Alligator" and dispatched by the control of the society the land which later became Liberta.

From 1836–98 he lived in Princeton, devoting his attention to the foundation of the New Jersey Colonization society, of which he was first president, and to the construction of the Delaware and Raritan canal, which owed its existence to him. He was responsible for obtaining the charter for the canal, for financing it with his own fortune and for directing it as president during the last years of his life.

In 1838 he went to sea sagin, as commander of the flagship of the Moditerranean feet. John Tyler asked hun to join his cabinet as secretary of the navy, but Stockton refused, preferring to remain on active duty. With John Ericson, later designer of the "Monditor," he drew up plans for the "Princeton," the first warship to be driven with a scree propeller, designing, himself, one of its guns, the largest in the U.S. fleet. On one of the ship's first voyages, Stockton's gun was fired and exploded, killing the secretaires of state and the navy and wounding numerous other passengers, but Stockton was absolved of all blassleved of states.

In 1845 he was chosen by Tyler to sail in the "Princeton" to Texas to deliver to the state government the annexation resolution of the U.S government, and later in the same year he comwhere he had been ordered to take command of the fleet from Commodore John Sloat. War with Mexico having broken out while he was en route, Stockton immediately took command of U.S land and sea forces, capturing Los Angeles, the Mexican stronghold, on Aug 13, 1846

Stockton at once set up a civil government, naming as governor John C Frémont, who had been associated with him in the fighting He subsequently fought and defeated the Mexicans at San Diego, San Gabriel and La Mesa, after which Los Angeles, which the Mexicans had recaptured, again fell to the US forces. The entire province of California was then ceded to the United States

Stockton returned east in 1847 and resigned from the navy three years later, on May 28, 1850. He served in the U.S senate from 1851-53 and after 1853 was president of the Delaware and

Raritan Canal company. He died Oct 7, 1866

STOCKTON, a city of central California, U.S A, at the head of tidewater on the San Joaquin river, 80 mi E of San Francisco; the county seat of San Joaquin county. It is on the Pacific highway; has a municipal airport; and is served by the Santa Fe, the Southern Pacific, the Western Pacific, electric and Beltline railways, by motor coach and truck lines, population (1950) 70,853;

(1940) 54,714 by federal census.

Stockton has a level site averaging 23 ft above sea level, surrounded by the fertile lands of the San Toaquin valley, which produce potatoes, onions, beans, corn, asparagus, grain, Tokay grapes and other fruits. More than 100 crops are grown in the county, valued in 1949 at \$107,000,000. It is the site for California's only inland deepwater port completed in 1933, reaching the Pacific ocean through San Francisco via a channel 80 mi, long and 32 ft deep. The value added by manufactures in Stockton in 1947 was \$63,949,000; bank debits in 1949 totalled \$775,885,623 and the assessed valuation of property for 1949 was \$77,900,740. Stockton is the seat of the College of the Pacific, the oldest moorporated coeducational institution of the state, chartered in 1851. located in Santa Clara until 1871, and in San Jose from 1871 to 1922.

There was a small settlement there (called Tuleberg) before the discovery of gold in the Mother Lode. With the coming of the first gold seekers the importance of the site as an outfitting point for the mining country immediately became apparent. A town was laid out in the spring of 1840 by Captain Weber and named after Robert Field Stockton, who had been prominent in the events which secured California for the United States In 1850 Stockton became the county seat and was chartered as a city.

STOCKTON-ON-TEES, a municipal and parliamentary of the River Tees, 112 mi. above its mouth and opposite Thornabyon-Tees Pop. (1951) 74.024. Area 9.4 sq.mi. Stockton's first market charter was granted in 1310 and it is still a big market centre for cattle and agricultural produce Because of the presence of iron ore in the Cleveland hills to the south (which has long been mined) and the Durham coal field to the north, it grew into a big industrial centre and the leading Tees port until superseded by Middlesbrough. The port has 980 ft, of quavage, a minimum depth of 12 ft. at low water ordinary spring tide and 221 ft. at high water ordinary spring tide and trades principally with Scandinavia and the Netherlands The historic Stockton-Darlington railway (opened 1825) was the first passenger-carrying railway. Stockton is interested in the development of diesel and electric locomotives. Many light industries are located in the town and partly within the borough is the Imperial Chemical Industries establishment at Billingham,

Stockton grew up around the manor house and later castle of the bishops of Durham, to whom the town belonged. It is said that King John granted a charter in 1214, but no trace of this The borough is first mentioned in 1283. Since 1867 Stockton has sent one member to parliament,

At Norton, 1 mi. north, St. Mary's church, once collegiate, shows Saxon and Norman work and has the remains of a fine three-decker

STOCKYARDS are facilities consisting of pens or other

manded the "Congress" in its voyage from Norfolk to the Pacific, inclosures, and their appurtenances, in which livestock—cattle, swine, sheep and goats-are received, held or kept for sale, delivery or shipment in commerce Typically, they may be classified as public stockyards, private stockyards, concentration yards and auction markets Public stockvards are characteristically North American, private stockyards, South American, and auction markets. British Yet markets containing the characteristics of each are present in all large livestock-producing countries.

Public Stockwards are customarily conducted and operated as public markets and are available to all sellers and buyers of livestock who comply with established regulations. In many countries public stockyards are also publicly owned and operated by municipalities, as in Buenos Aires, or by state governments, as in Australia In the United States, they are generally privately owned and operated by a stockyard company in which corporate stock is widely owned The principal public stockyards and auction markets of the United States and Canada are posted and regulated under similar statutes, viz, the Packers and Stockyards act, TO2T, and the Layestock and Layestock Products act, 1030. In the 1050s there were about 65 primary public stockyards and 260 auction markets in the U.S., and 11 public stockyards in Canada so regulated

A considerable number of secondary public stockyards in the US, because of size or the intrastate character of their business, had not been subjected to federal regulation, but in some cases and in some respects are regulated by state agencies. A typical year of activity was 1952, in which the 65 primary public stockyards in the U.S. received for sale or delivery to packers 23,727,996 cattle and calves, 38,017,093 swine, and 15,771,683 sheep, lambs and goats In the same year, the 11 stockyards in Canada received 1,314,446 cattle and calves, 1,034,880 swine and 189,804 sheep and lambs

Public stockyard owners are required to furnish without discrimination reasonable facilities and services in connection with the receiving, handling, feeding, watering, holding, delivery, weighing and shipment of hyestock. They do not sell or buy any livestock either for their own account or as agents for sellers or buyers They are required to publish, file with the government, and observe a schedule of reasonable charges for the use of facilities and services offered. While any owner may ordinarily sell his own livestock at a public stockyard, he customarily consigns it to one of the market agencies or commission firms authorized and registered to perform selling services on an agency basis at that stockyard The market agencies doing business at a public stockyard must register with the regulatory agency, provide a surety bond to assure the prompt payment of the proceeds of sales; publish, file and observe a schedule of commission charges for the services furnished; and establish and observe just and reasonable regulations and practices in respect to such services Market agencies provide competent selling services comparable to the skill of the buyers; collect the amount of the sale from the buyer; and remit the net proceeds of the sale to the consignor, retaining their authorized commission and paying the carrier, the stockward owner. and others, the legal freight, vardage, feed and other charges.

Public markets are usually operated 5 or 6 days each week. Customarily there are present buyers representing adjacent packers, butchers, order buyers representing packers at other points. dealers who buy and sell for their own account for speculative profit, and buyers of feeder or store livestock seeking animals for further grazing, feeding or fattening. Order buyers and dealers regularly engaged in business on a public stockyard must register with the government and provide suitable surety bonds to insure the payment for all livestock purchased. Packers and other buyers may be required to provide a bond, give assurance of financial responsibility or pay for purchases before the livestock is delivered to them.

Sales at public stockyards are negotiated privately and individually between the buyers and market agents in the pens containing the livestock, which may be sorted into separate lots of comparable kind, quality or size to facilitate the sale of each consignment on its ments Livestock is weighed by the stockyard owner and held until delivered or shipped to the buyer. Prices

agreed upon by the seller and the buyer are assembled and published by the market news services of the respective departments of agriculture or by registered market agencies for the use of producers, market men and buyers generally

To control and prevent the spread of livestock diseases and protect the public health, the bureau of animal industry of the US department of agriculture maintains constant inspection at many public stockyards Other state, municipal or national agencies maintain a similar inspection service at other public stockyards

Private Stockyards are operated by packers as adjuncts to their packing plants or by dealers for the purchase of livestock for speculative profit, the only buyer present being the representative of the packer or the dealer operating the yards. In South America, price arrangements are made before the livestock goes to the packer's yard, but in the U.S. prices are usually determined on receipt at the private yard. In Canada the prices, especially of hogs, are often determined after slaughter upon carcass weight and grade Many private stockyards are located at interior points in productive livestock regions away from the public market centres

Concentration Yards, typical of the U.S., are generally only another designation for private stockyards operated as assembly points in surplus livestock producing areas by packers located some distance away, by dealers who buy for their own account and in turn sell to such packers, by order buyers who buy on order as agent for packers, or by co-operative associations Hogs and calves are principally purchased at concentration yards, although there are occasional purchases of cattle and sheep Transportation privileges, such as unloading, sorting, regrouping and reshipment at the balance of through rates, which concentration yards formerly enjoyed, are no longer of great importance since most of the shipments to, and many of the shipments from, concentration yards now move by motor truck While most operators of private stockyards and concentration yards will buy livestock from anvone who will sell to them, they may discriminate in the person from whom they buy or in the price or the conditions of any purchase They generally provide and operate the facilities used. including the scales upon which the livestock is weighed. They are not regulated as public markets.

Auction Markets are a type of public market widely distributed over the world. They are often owned or operated by the auctioneers who conduct both the selling and the general operations of the yards, although in some cases the facilities are owned and operated by an individual, firm, corporation or municipality, with the selling conducted by the auctioneer under a lease, permit

or employment arrangement.

Auction markets conduct their sales under competitive, oral or written bidding either in a central auction ring or from pen to pen in the yards, usually one or two days a week, with some private trading carried on throughout the week. In some countries, where prices and sale conditions are strictly regulated, auction markets become a type of concentration yards or collecting centres for the controlled livestock, usually livestock intended for immediate slaughter. In Canada, and in a few cases in the U.S., some kinds and classes of livestock are regularly or occasionally sold at auction in public stockyards.

Most producers and packers have a choice of one or more of all four types of markets Public stockyards are the principal mar-kets used. Following World War I, shifting production and population, changes in transportation and refrigeration, and the use of motor trucks encouraged decentralization of the packing industry. a large part of which moved nearer to producing areas. Packers adjacent to public stockyards in order to maintain their competitive position increased their purchases direct from producers. private stockyards, concentration yards, and auction markets, and decreased the proportion of livestock purchased at public stock-

Livestock is produced chiefly in the corn belt and central plains section of the U.S., while meat consumption is concentrated in the populous coastal regions. Fluctuating supplies and demands from all directions increased the importance of public stockyards, the principal function of which is to effect an equitable distribution of total production through the medium of sensitive prices determined under favourable conditions

STODDARD, AMOS (1762-1813), U S soldier, was born in Woodbury, Conn , Oct. 26, 1762. He enlisted in the colonial army in 1779, serving until the close of the Revolutionary War, when he became a clerk of the Massachusetts supreme court. He spent the years from 1793-98 as a lawyer in Hallowell, Me., serving for one year (1797) in the legislature of Massachusetts, of which Mame was at that time a district. In 1798 he rejoined the army, receiving a captain's commission on his entrance and becoming a major in 1807 and deputy quartermaster in 1812. the territory of Louisiana was purchased by the United States, Stoddard was chosen to accept the territory from Spain in the name of France and to accept it the following day from France in the name of the United States. He was then named civil and military governor of the territory, a post he held for the few months in 1804 before congress set up a government. He was assigned to Fort Meigs, Ohio, during the War of 1812 and during the siege of that post received a fatal wound. He died May II, 1812

Stoddard was the author of The Political Crisis (1701), written and published in London during a visit he made in his youth, and of Sketches, Historical and Descriptive, of Louisiana (1812).

STODDARD, JOHN LAWSON (1850-1931), U.S. writer and lecturer, was born in Brookline, Mass, on April 24, 1850. He graduated from Williams college in 1871 and attended the Yale Divinity school for the following two years. After some years of teaching and travel he began, in 1879, his successful career as a travel lecturer.

Stoddard continued to travel and lecture for almost 20 years, delivering each year the illustrated Stoddard lectures on European, American and Oriental travel. During the period he published various travel and picture books, including the well known series, John L Stoddard's Lectures which first appeared (1897-98) in ten volumes Stoddard spent his later years in retirement in Europe, devoting himself to writing and editing and after 1917 to religious study His published works include Glimpses of the World (1892); Stoddard Lectures on Travel Abroad and in America, 15 vol (1898-1909), Beautiful Scenes of America (1902), The Stoddard Library; A Thousand Hours of Entertainment with the World's Great Writers, 12 vol. (1910); Rebuilding a Lost Faith (1921); Two Arguments for Catholicism (1927). He died in Europe in June 1931.

STODDARD, RICHARD HENRY (1825-1903), U.S.

writer, was born in Hingham, Mass., July 2, 1825. As a boy Henry Stoddard read whatever he could find, and wrote and revised conscientiously and continuously. The literati of New York were kind, and soon Stoddard was contributing frequently to magazines and saving up money enough to have his first book Footprints (1848) published. Nathaniel Hawthorne helped him to secure a position in the New York customhouse (1853-70). Later he was private secretary to Gen. George B McClellan in the New ne was private serically to dean. Georgia in MacCleand in la New York York dock department (1870–73); city librarian of New York (1874–75); literary edutor of the New York World (1860–70) and the Mail and Express (1880–1903); and editor of the Aldime (1869–74). He died in New York, May 12, 1903. Stoddard's

poems are sincere, original and felicitous in form.

STODDARD, WILLIAM OSBORN (1835-1925), U.S. writer and secretary to President Lincoln, was born in Homer, N.Y., Sept. 24, 1835. He graduated from the University of Rochester in 1858 and in the same year became coeditor of the Central Illinois Gazette. He proposed Lincoln for the presidency in the columns of the Gazette and actively supported him in the presidential campaign of 1860. He served as a secretary to the president from 1861 to 1864 and in 1864 was appointed U.S. marshal of Arkansas.

Stoddard wrote more than 100 books, including: Abraham Lincoln (1884); The Lives of the Presidents, 10 vol. (1886-89); Inside The White House in War Times (1890); and The Table Talk of Lincoln (1894). He died in Madison, N.J., on Aug. 29, STODDERT, BENJAMIN (1751-1813), first US secretary of the navy, was born in Chales county, Md, in 1751 He planned to be a merchant, but at the outbreak of the Revolutionary Wat, poined the army and served for a time as a cavalty officer. From 1750-81 he was secretary of the board of war and from 1761-98 he conducted a highly successful shipping business in Georgetown, Md. He was one of the men whom George Washington commissioned to purchase tracts of land in what is now the District of Columbia, to be repurchased later by the government and used as the site of the national capital

In May 1798, Stoddert joined the cabinet of John Adams as first secretary of the new navy department, although Adams had previously offered the position to George Cabot, who refused Stoddert's experience stood him in good stead in his new post When he took office the US navy consisted of little more than three frigates. When he left office, in 1801, he had enlarged it to more than 50 ships, which were able to defeat the French in the short and undeclared naval war between the two countries (1708-1800). He also authorized the purchase of land in six locations on the eastern seaboard for the construction of navy yards and was responsible for organizing the marine corps on the basis on which it still operates. During his secretaryship of the navy, Stoddert also served as head of the war department for a brief period between incumbents. He left office with Adams and returned to his business but it never prospered again and he died in Bladensburg, Md, Dec 18, 1813, a poor man.

STOECKEL, CARL (1858-1925) U.S. music patton, was born in New Haven, Com. Dec. 7, 1858. In the late 19th century he settled in Norfolk, Conn., where he and his wife founded the Letchfield County Choral union, which eventually included the membership of five choral groups from the vicinity of Licfaeld. In 1906 he built a "Music Shed" for the annual concerts of the group which, into following year, first legan to supplement their choral music with programs of orchestral music. By 1911 there were 700 singers in the choral union and their concerts, known as the Norfolk festival, were events of international importance in the music world Some of the most noted of modern composers served as conductors of the festival and many of them, including Johan Sibelus, wrote music especially for performance there The festivals were discontinued after Stoeckel's death. on Nov. 1, 1925

STOESSEL, ALBERT (1894–1943), U.S. conductor and composer, was born in St. Louis, Mo, Oct 11, 1894. He studied in Berlin, Ger, and made his debut as a violinist there in 1914, returning afterward to the United States. He became conductor of the New York (or Oator) society in 1921 and head of the music department of New York university in 1923. He conducted the Worcester (Mass) music festivals from 1925 to 1942. His opera Garrick, on the life of the famous actor, was produced in New York city of the 24, 1937, he also composed several orchestral works He died in New York city of May 12, 1943, while conducting Wulter Damosch's symphonic poem Dunkthe. (N. N. S)

STOFFLET, JEAN NICOLAS (1751-1796), Vendéan general, was born at Lunéville, the son of a miller. Long a private soldier in a Swiss regiment in France, and afterward gamekeeper to the comte de Colbert-Maulevrier, he joined the Vendéans when they rose against the Revolution to defend their religious and royalist principles During the war in La Vendée he served first under Gigot d'Elbée, fought at Fontenay, Cholet and Saumur, and distinguished himself at the battles of Beaupréau, Laval and Antrain. He was appointed major-general of the royalist army and in 1794 succeeded La Rochejaquelein as commander-in-chief, He accepted the terms of the treaty of La Jaunale (May 2, 1795) but he soon violated them, and at the instigation of royalist agents took arms in Dec. 1795 on behalf of the count of Provence (the future Louis XVIII), from whom he had received the rank of maréchal-de-camp. This last attempt of Stofflet's failed completely. He was taken prisoner by the republicans, condemned to death by a military commission, and shot at Angers on Feb. 23,

See General d'Andigné, Mémoires, edited by E. Biré (1900-01); C. Loyer, "Cholet sous la domination de Stofflet," in L'Anjou historique, vol m (1902-03).

STOICHEIOMETRY, in chemistry, is a term which, structly, denotes the determination of the proportions in which elements or compounds react with one another, and is occasionally extended to include the determination of atomic and molecular weights (Gr \u03c4\

STOICS, a school of philosophers founded at the close of the 4th century BC by Zeno of Citium, and so called from the Stoa or painted corridor (στοὰ ποικίλη) on the north side of the marketplace at Athens, which, after its restoration by Cimon, the celebrated painter Polygnotus had adorned with frescoes representing scenes from the Trojan War But, though it arose on Hellenic soil, from lectures delivered in a public place at Athens, the school is scarcely to be considered a product of purely Greek intellect, but rather as the firstfruits of that interaction between west and east which followed the conquests of Alexander Hardly a single Stoic of eminence was a citizen of any city in the heart of Greece, unless we make Aristo of Chios, Cleanthes of Assus and Panaetius of Rhodes exceptions Such lands as Cyprus, Cilicia and Syria, such cities as Citium, Soh, Heraclea in Pontus, Sidon, Carthage, Seleucia on the Tigris, Apamea by the Orontes, furnished the school with its scholars and presidents, Tarsus, Rhodes and Alexandria became famous as its university towns. As the first founder was of Phoenician descent, so he drew most of his adherents from the countries which were the seat of Hellenistic (as distinct from Hellenic) civilization; nor did Stoicism achieve its crowning triumph until it was brought to Rome, where the grave earnestness of the national character could appreciate its doctrine, and where for two centuries or more it was the creed. if not the philosophy, of all the best Romans Properly therefore it stands in marked antithesis to that fairest growth of old Hellas, the Academy, which saw the Stoa rise and fall-the one the typical school of Greece and Greek intellect, the other of the Hellenized east, and, under the early Roman empire, of the whole civilized world The transcendent genius of its author, the vitality and romantic fortunes of his doctrine, claim our warmest sympathies for Platonism But it should not be forgotten that for more than four centuries the tide ran all the other way It was Stoicism, not Platonism, that filled men's imaginations and exerted the wider and more active influence upon the ancient world at some of the busiest and most important times in all history

The history of the Stoic school may conveniently be divided in the usual threefold manner; the old Stoa, the middle or transition period (Diogenes of Seleucia, Boethus of Sidon, Panetius, Positionius), and the later Stoicason of Roman times. By the old Stoa is meant the period (c. 304-205 R.C.) down to the death of Chrysippus, the second founder; then was laid the foundation of theory, to which hardly anything of importance was afterward added. Confined almost to Atheas, the school made its way slowly among many rivals Aristo of Chios and Herillus of Carthage, Zeno's heterodox pupils, Perseus, his favourite disciple and housemate, the poet Aratus, and Sphierus, the adviser of the Spartan king Cleomenes, are noteworthy minor names, but the chief interest centres about Zeno, Cleanthes, Chrysippus, who in succession built us the wondrous system.

Zeno.—Zeno's residence at Athens fell at a time when the great movement which Socrates originated had spen tiself in the second generation of his spiritual descendants. Neither Theophrastus at the Lyceum, nor Xenocrates and Polemo at the Academy, nor Stilpo, who was drawing crowds to hear him at Megara, could be said to have inherited much of the great reformer's intellectual vagour, to say nothing of his moral earnestness. Zeno visited all the schools in turn, but seems to have attached himself definitely to the Cynics; as a Cynic he composed at least one of his more important works, "the much admired Republic," which we know

STOICS 43I

to have been later on a stumbling-block to the school. In the sonal characteristics can be traced the hair-splitting and formal Cynic school he found the practical spirit which he divined to be the great need of that stirring troublous age. For a while his motto must have been "back to Socrates," or at least "back to Antisthenes." The Stoics always counted themselves amongst the Socratic schools, and canonized Antisthenes and Diogenes, while reverence for Socrates was the tie which united to them such an accomplished writer upon lighter ethical topics as the versatile Persaeus, who, at the capital of Antigonus Gonatas, with hardly anything of the professional philosopher about him, reminds us of Xenophon, or even Prodicus Zeno commenced, then, as a Cynic, and in the developed system we can point to a kernel of Cynic doctrine to which various philosophemes of other thinkers (more especially Heraclitus and Aristotle, but also Diogenes of Apollonia, the Pythagoreans, and the medical school of Hippocrates m a lesser degree) were added. Thus, quite apart from the general similarity of their ethical doctrine, the Cynics were materialists; they were also nominalists, and combated the Platonic ideas, in their theory of knowledge they made use of "reason" (λόγος), which was also one of their leading ethical conceptions. In all these particulars Zeno followed them, and the last is the more important, because, Chrysippus having adopted a new criterion of truth-a clear and distinct perception of sense-it is only from casual notices we learn that the elder Stoics had approximated to Cynicism in making right reason the standard At the same time, it is certain that the main outlines of the characteristic physical doctrine, which is after all the foundation of their ethics and logic, were the work of Zeno The Logos, which had been an ethical or psychological principle to the Cynics, received at his hands an extension throughout the natural world, in which Heraclitean influence is unmistakable

Cleanthes .- If the recognition of physics and logic as two studies co-ordinate with ethics is sufficient to differentiate the mature Zeno from the Cynic author of the Republic, no less than from his own heterodox disciple Aristo, the elaboration on all sides of Stoic natural philosophy belongs to Cleanthes, who certainly was not the merely docile and receptive intelligence he is sometimes represented as being. He carried on and completed the assimilation of Heraclitean doctrine; but his own contributions were more distinctive and original than those of any other Stoic He was able to transform Zeno's seeming dualism of God (or force) and formless matter into the lofty pantheism which breathes in every line of the famous hymn to Zeus. Herachtus had indeed declared all to be in flux, but we ask in vain what is the cause for the unceasing process of his ever-living fire. It was left for Cleanthes to discover this motive cause in a conception familiar to Zeno, as to the Cynics before him, but restricted to the region of ethics-the conception of tension or effort. The soul of the sage, thought the Cymics, should be strained and braced for judgment and action, his first need is firmness (ebrovia) and Socratic strength But the mind is a corporeal thing. Then followed the flash of genius this varying tension of the one substance everywhere present, a purely physical fact, accounts for the diverse destinies of all mnumerable particular things, it is the ventable cause of the flux and process of the universe. Herein lies the key to the entire system of the Stoics, as Cleanthes's epoch-making discovery continually received fresh applications to physics, ethics and epistemology.

Chrysippus.-Zeno had caught the practical spirit of his age the desire for a popular philosophy to meet individual needs. But there was another tendency in post-Aristotelian thought-to lean upon authority and substitute learning for independent researchwhich grew stronger just in proportion as the fresh interest in the problems of the universe and the zeal for discovery declined-a shadow, we may call it, of the coming Scholasticism thrown a thousand years in advance. The representative of this tendency, Chrysippus, addressed himself to the congenial task of assimulating, developing, systematizing the doctrines bequeathed to him. and, above all, securing them in their stereotyped and final form, not simply from the assaults of the past, but, as after a long and successful career of controversy and polemical authorship he

pedantry which ever afterwards marked the activity of the school, the dry repellent technical procedure of the Dialecticians par excellence, as they were called He created their formal logic and contributed much that was of value to their psychology and epistemology, but in the main his work was to new-label and newarrange in every department, and to lavish most care and attention on the least important parts-the logical terminology and the refutation of fallacies, or, as his opponents declared, the excogitation of fallacies which even he could not refute.

Stoic Conception of Philosophy.-What is philosophy? No idle gratification of curiosity, no theory divorced from practice, no pursuit of science for its own sake, but knowledge so far forth as it can be realized in virtuous action, the learning of virtue by exer cise and effort and training So absolutely is the "rare and price less wisdom" identical with virtue itself that the three main divisions of philosophy current at the time and accepted by Zeno -logic, physics and ethics-are defined as the most generic or comprehensive virtues. Accordingly Aristo rejected two of these parts of philosophy as useless and out of reach-a divergence which excluded him from the school, but strictly consistent with his view that ethics alone is scientific knowledge. Of the three divisions logic is the least important; ethics is the outcome of the whole, and historically the all-important vital element, but the foundations of the whole system are best discerned in the science of nature, which deals pre-eminently with the macrocosm and thé microcosm, the universe and man, including natural theology and anthropology or psychology, the latter forming the direct introduction to ethics

Physics.—The Stoic system is in brief: (a) materialism, (b) dynamic materialism, lastly (c) monism or pantheism (a) The first of these characters is described by anticipation in Plato's Sophist (246 C seq ), where, arguing with those "who drag everything down to the corporeal"  $(\sigma \hat{\omega} \mu a)$ , the Eleatic stranger would fain prove to them the existence of something incorporeal, as follows "They admit the existence of an animate body Is soul then something existent (ovola)? Yes And the qualities of soul, as justice and wisdom-are they visible and tangible? No Do they then exist? They are in a dilemma" Now, however effective against Plato's contemporary Cynics or Atomists, the reasoning is thrown away upon the Stoics, who take boldly the one horn of this dilemma That qualities of bodies (and therefore of the corporeal soul) exist they do not deny; but they assert most uncompromisingly that they are one and all (wisdom, justice, etc.) corporeal And they strengthen their position by taking Plato's own definition (247 D), namely "being is that which has the power to act or be acted upon," and turning it against him For this is only true of Body; action, except by contact, is inconcervable; and they reduce every form of causation to the efficient cause, which implies the communication of motion from one body to another Again and again, therefore, only Body exists. The most real realities to Plato and Aristotle had been thought and the objects of thought, νοθs and νοητά, whether abstracted from sensibles or inherent in "matter," as the incognizable basis of all concrete existence. But this was too great an effort to last long Such spiritualistic theories were nowhere really maintained after Aristotle and outside the circle of his immediate followers The reaction came and left nothing of it all; for five centuries the dominant tone of the older and the newer schools alike was frankly materialistic. "If," says Aristotle, "there is no other substance but the organic substances of nature, physics will be the highest of the sciences," a conclusion which passed for axiomatic until the rise of Neoplatonism. The analogues therefore of metaphysical problems must be sought in physics; particularly that problem of the causes of things for which the Platonic idea and the Peripatetic "constitutive form" had been, each in its turn, received solutions. (b) But the doctrine that all existence is confined within the limits of the sensible universe-that there is no being save corporeal being or body-does not suffice to characterize the Stoic system; it is no less a doctrine of the Epicureans. It is the idea of tension or tonicity as the essential attrifondly hoped, from all possible attack in the future. To his per- bute of body, in contradistinction to passive inert matter, which 432 STOICS

is distinctively Stoic. The Enjoyreans leave unexplained the primary constitution and first movements of their atoms or elemental solids, chance or declination may account for them Now, to the Stoics nothing passes unexplained, there is a reason (λόγος) for everything in nature Everything which exists is at once capable of acting and being acted upon In everything that exists, therefore, even the smallest particle, there are these two principles By virtue of the passive principle the thing is susceptible of motion and modification; it is matter which determines substance (obota). The active principle makes the matter a given determinate thing, characterizing and qualifying it, whence it is termed quality (ποιότης). For all that is or happens there is an immediate cause or antecedent; and as "cause" means "cause of motion," and only body can act upon body, it follows that this antecedent cause is itself as truly corporeal as the matter upon which it acts Thus we are led to regard the active principle "force" as everywhere coextensive with "matter," as pervading and permeating it, and together with it occupying and filling space This is that famous doctrine of universal permeation (κράσις δί όλου), by which the axiom that two bodies cannot occupy the same space is practically denied. Thus that harmony of separate doctrines which contributes to the impressive sumplicity of the Stoic physics is only attained at the cost of offending healthy common sense, for Body itself is robbed of a characteristic attribute A thing is no longer, as Plato once thought, hot or hard or bright by partaking in abstract heat or hardness or brightness, but by containing within its own substance the material of these qualities, conceived as air-currents in various degrees of tension We hear, too, of corporeal days and years, corporeal virtues, and actions (like walking) which are bodies (σώματα) Obviously, again, the Stoic quality corresponds to Aristotle's essential form; in both systems the active principle, "the cause of all that matter becomes," is that which accounts for the existence of a given concrete thing (λόγος της οὐσίας). Only here, instead of assuming something immaterial (and therefore unverifiable), we fall back upon a current of air or gas (πνεθμα), the essential reason of the thing is itself material, standing to it in the relation of a gaseous to a solid body. Here, too, the reason of thingsthat which accounts for them-is no longer some external end to which they are tending; it is something acting within them, "a spirit deeply interfused," germinating and developing as from a seed in the heart of each separate thing that exists (λόγος σπερματικός). By its prompting the thing grows, develops and decays, while this "germinal reason," the element of quality in the thing, remains constant through all its changes,

Psychology and Theory of Knowledge.-If, however, in the science of nature the Stoics can lay claim to no striking originality, the case is different when we come to the science of man. In the rational creatures-man and the gods-Pneuma is manifested in a high degree of purity and intensity as an emanation from the world-soul, itself an emanation from the primary substance of purest ether—a spark of the celestial fire, or, more accurately, fiery breath, which is a mean between fire and air, characterized by vital warmth more than by dryness The physical basis of Stoic psychology deserves the closest attention. On the one hand, soul is corporeal, else it would have no real existence, would be incapable of extension in three dimensions (and therefore of equable diffusion all over the body), incapable of holding the body together, as the Stoics contended that it does, herein presenting a sharp contrast to the Epicurean tenet that it is the body which confines and shelters the light vagrant atoms of soul. On the other hand, this corporeal thing is veritably and identically reason, mind, and ruling principle (λόγος, μους, ήγεμονικόν); in virtue of its divine origin Cleanthes can say to Zeus, "We too are thy offspring," and a Seneca can calmly insist that, if man and God are not on perfect equality, the superiority rests rather on our side. What God is for the world that the soul is for man. The Cosmos must be conceived as a single whole, its variety being referred to varying stages of condensation in Pneuma. So, too, the human soul must possess absolute sim-plicity, its varying functions being conditioned by the degrees or species of its tension. It follows that of "parts" of the soul,

as previous thinkers imagined, there can be no question; all that can consistently be maintained is that from the centre of the body—the heart—seven distinct air-currents are discharged to various organs, which are so many modes of the one soul's activity. The ethical consequences of this position will be seen at a later stage. With this psychology is unimately connected the Stote theory of knowledge. From the unity of soul it follows that all psychical processes—ensation, assent, impulse—proceed from reason, the ruling part; that is to say, there is no strife or division the one rational soul alone has sensations, assents to judgments, is impelied towards objects of desire just as much as it thinks or reasons.

Cosmopolitanism .- In their view of man's social relations the Stoics are greatly in advance of preceding schools We saw that virtue is a law which governs the universe; that which Reason and God ordain must be accepted as binding upon the particle of reason which is in each one of us. Human law comes into existence when men recognize this obligation, justice is therefore natural and not something merely conventional The opposite tendencies, to allow to the individual responsibility and freedom, and to demand of him obedience to law, are both features of the system, but in virtue even of the freedom which belongs to him qua rational, he must recognize the society of rational beings of which he is a member, and subordinate his own ends to the ends and needs of this society. Those who own one law are citizens of one state, the city of Zeus, in which men and gods have their dwelling In that city all is ordained by reason working intelligently, and the members exist for the sake of one another; there is an intimate connection (συμπάθεια) between them which makes all the wise and virtuous friends, even if personally unknown, and leads them to contribute to one another's Their intercourse should find expression in justice, in friendship, in family and political life. But practically the Stoic philosopher always had some good excuse for withdrawing from the narrow political life of the city in which he found himself. The circumstances of the time, such as the decay of Greek citylife, the foundation of large territorial states under absolute Greek rulers which followed upon Alexander's conquests, and afterwards the rise of the world-empire of Rome, aided to develop the lead-ing idea of Zeno's Republic. There he had anticipated a state without family life, without law courts or coms, without schools or temples, in which all differences of nationality would be merged in the common brotherhood of man. This cosmopolitan citizenship remained all through a distinctive Stoic dogma; when first announced it must have had a powerful influence upon the minds of men, diverting them from the distractions of almost parochial politics to a boundless vista. There was, then, no longer any difference between Greek and barbarian, between male and female, bond and free
